I.—GENERAL; PLANT; MACHINERY.

Refrigerating machine employing compression supplementary to high condenser pressures; Test of a carbon dioxide ——. R. Plank. Z. ges. Kälteind., 1921, 28, 157—162. Chem. Zentr., 1922, 93, II., 1102.

The efficiency of compression refrigerating machines in which the working fluid operates in the neighbourhood of the critical state can be increased by submitting the compressed and cooled vapour, or condensed fluid, to subsequent compression followed by further cooling. Thus in a test carried out, not under particularly favourable conditions, an increased power consumption of about 7% for the auxiliary compression increased the cooling efficiency by 18%. The increased efficiency is somewhat greater than anticipated from theoretical considerations on account of the efficiency of the principal compressor being increased owing to diminished thermal losses.—J. S. G. T.

Adsorption of vapours; Calculation of —— at different temperatures. L. Berényi. Z. angew. Chem., 1922, 35, 237—238.

Formulæ and tables are given by means of which it is possible to calculate from the x_1 (quantity adsorbed) and p_1 (pressure) values for a measured adsorption isotherm (at temperature T_1), the corresponding x and p values for other temperatures over a range extending, for substances boiling between 170° and 400° abs., from 0·6 to 1·4 times the boiling point in ° abs. The method is based on Polanyi's theory of adsorption (Verh. Deuts. Phys. Ges., 1914, 16, 1012; 1916, 18, 55; Z. Elektrochem., 1920, 26, 370; Festschr. Kaiser-Wilhelm-Ges., 171) and applies only to the reversible, physical adsorption of chemically homogeneous vapours, alone, or of such vapours from admixtures with comparatively inert gases. The application of the method to published experimental data is described.—H. M.

Adsorption of solutions; General theory of the ——. Wo. Ostwald and R. de Izaguirre. Kolloid-Zeits., 1922, 30, 279—306.

Every adsorption is at first a process of separation, whereby a concentrated solution, the adsorbed solution, forms at the surface of the adsorbent, whilst the equilibrium solution remains behind. The adsorption of the solvent along with the dissolved substance is an important part of every adsorption. (*Cf.* J.C.S., July.)—J. F. S.

Patents.

Liquids of different density [*e.g.*, *oil and water*]; *Separators employed for separation of* ——. W. H. Bateman. E.P. 179,209, 8.11.20.

A "tail-box" for the separation of oil and condensed water produced during the steam distillation of oils is so constructed that it may be attached to any form of separating chamber, and is divided by vertical partitions into four compartments. The first or water discharge compartment is connected with the bottom of the separating chamber and has an overflow pipe of adjustable level so that the column of water therein is balanced by the column of oil and water in the separating chamber. The next compartment is connected with the separator just below the top level of the oil therein and with a third compartment at the same height as the oil level, thus providing a liquid seal in the connexion between the second compartment and the separator to prevent gas loss. The third compartment is furnished with an oil discharge pipe. The fourth compartment is a sight box and has connexions in its upper part with the second (oil) compartment and in its lower part with the first (water) compartment.—F. G. P. R.

Separating solids by crystallisation from solvents; Process for ——. F. W. Berk and Co., and H. V. A. Briscoe. E.P. 179,287, 1.2.21.

To resolve a mixture of two substances into its constituents a solution of the mixture is brought to conditions of concentration and temperature at which one substance only tends to crystallise out on cooling, the solution is cooled, and the crystals of the first substance are separated before the second substance begins to crystallise. The solution is then brought to conditions of concentration and temperature at which the second substance only tends to crystallise out on cooling, the solution is cooled, and the crystals of the second substance are separated before the first substance begins to crystallise. The solution is then again brought to conditions of concentration and temperature at which either substance only tends to crystallise on cooling. The application to the separation of a mixture of potassium nitrate and sodium nitrate is described in detail.—H. H.

Oils; Means of effecting heat interchange between two fluids, particularly applicable for use in distilling ——. T. E. Robertson. From Power Specialty Co. E.P. 179,493, 26.11.20.

In apparatus for heating fluids, such as pipe stills or steam superheaters, the pipes nearer the furnace receive more heat than those more remote, with consequent danger of over-heating the contained fluid. In order to equalise the amount of heat transmitted to the fluid along the whole system of pipes, the latter are enclosed in corrugated casings on which the depths of the corrugations vary more or less inversely, whilst the thickness of the body of the casing varies directly, as the temperature difference between the heating and heated fluids.
—F. G. P. R.

Recuperators for use in connexion with furnaces. Façoneisen Walzwerk L. Mannstaedt und Co. A.-G., and H. Bansen. E.P. 179,639, 7.2.21.

The recuperators may be considered as made up of a series of units. Each unit consists of a number of horizontal waste gas flues, of square cross-section, built one above the other, and connected at their ends so as to form a continuous passage for the gas. A number of such units are placed parallel to one another, with spaces between them, and also between the outer walls and outer units. The gas flues are supported at the lower corners on brickwork, which extends almost the whole length of the flue, and also bridges the gap between the units and forms a support for the corresponding flue of the next unit. In this way there are formed round each gas flue four flues of rectangular section, two horizontal, one above and one below the gas flue, and two lateral flues each extending the length of the gas flue. Waste gas enters the gas flues at the top and passes downwards through the plant. Air enters at the bottom and flows to the back of the plant through the horizontal flue below the lowest gas flue. Here there is an opening between this flue and the lateral flue through which the air returns to the front of the plant, where it enters through another opening the horizontal flue between the two gas flues. Travelling to the back by the horizontal flues and to the front of the plant through the lateral flues, the air gradually rises and is discharged at the top of the plant. When dealing with large quantities of air several gas flues are arranged to work in parallel. Among the advantages claimed for this invention are even distribution of air in horizontal and lateral flues, the possibility of directing air through the recuperators by any path, high speed of air, simplification of construction and repairs, and minimising of stresses set up in masonry.—S. G. U.

Kilns. G. Hughes. From Deutsche Evaporator A.-G. E.P. 179,674, 14.2.21.

The cooling chamber of the kiln is connected with the heating chamber by a yielding member, so that the expansion of the heating chamber is not transmitted to the cooling chamber. Two flat or bulged plates with centres removed to suit the cross-section of the kiln chambers have the inner edge of the one bolted to the flange of the heating chamber, and the inner edge of the other to the flange of the cold chamber. Gas-tight joints are formed at the outer edges of the plates, and in addition one of these yielding members is connected with one end of a plate, the other end of which has slots through which pass studs screwed into the second member, thus covering the gap between the yielding members.—S. G. U.

Kiln; Rotary ——. A. B. Carstens, Assr. to The American Metal Co. U.S.P. 1,415,990, 16.5.22. Appl., 8.12.19.

A rotary kiln is provided in its periphery with openings which are kept closed while the kiln rotates, except during the short period when material is fed into the kiln through them.
—J. S. G. T.

Distillation columns. C. Still and H. Petsch. E.P. 179,745, 15.3.21.

In a continuous column apparatus for the distillation of volatile constituents from a mixture of liquids of high and low boiling points, a preheater is placed between the still and the rectifying column. The sides of the preheater are in line with the sides of the still, and the cover of the still forms the base of the preheater, whilst the cover of the preheater forms the base of the rectifying column. Two channels pass through the base plate of the preheater. One, the downcomer, projects through the base plate into a tray placed in the top of the still, so as to form a seal between the preheater and the still. The other channel, which carries the vapour from the still to the top of the preheater, whence it passes through suitable openings into the rectifying column, is placed diametrically opposite and terminates at a higher level than the downcomer. Steam coils are fitted in the space between the channels, and the liquid to be distilled is fed into the preheater through a short straight perforated pipe placed below the coils. The condensed liquid on the trays of the rectifying column is also led into the preheater. Advantages claimed are elimination of a separate preheater, thus reducing heat losses; a simple path for both liquid and vapour; cheapening of cost and working of plant.
—S. G. U.

Filtering apparatus [*; Rotating valve for* ——]. E. W. W. Keene. E.P. 179,494, 11.3.21.

In a rotating valve for rotary or other continuous filters, the interior ported portion which communicates with the various sectors of the filter proper does not co-operate directly with the stationary outer part of the valve, but through adjustable sliding pieces working in an annular groove between the two main portions of the valve. The sliding pieces are adjustable from outside the cover of the valve, and control the ports by which connexion is made with a high vacuum for filtration, a low vacuum for washing, a supply of air under pressure for discharging, and an air exhaust.
—B. M. V.

Drying apparatus. C. Whitfield. E.P. 179,764, 23.3.21.

The drying chamber consists of a long chamber rectangular in section, having a charging arrangement at one end and a discharging device at the other. The floor of this chamber forms the roof of two smaller chambers; one, the combustion chamber, at the outlet end of the apparatus, extends about one third the length of the drying chamber, and is of rectangular section, whilst the other, about two thirds the length of the drying chamber, is of triangular section and has two outlets at the inlet end of the apparatus, one for condensed liquid and the other for spent gases. The drying chamber is fitted with a flue or flues connected with the inner end of the combustion chamber. The outlet of the flue or flues is turned downwards, so as to discharge the hot gases on to the material at the inlet end of the plant. The gases flow towards the discharging end and there enter two ducts embedded in the brickwork and having their outlets in the inner end of the triangular chamber, through which the gases flow to the charging end of the plant. The plant is particularly suitable for drying wet materials such as peat, which are unharmed by contact with the hot gases; the fuel consumption is small, and it is impossible for any moisture to collect at any point of the drying chamber.—S. G. U.

Dryer. K. Ladisch. U.S.P. 1,416,960, 23.5.22. Appl., 15.8.21.

A rotary perforated heating drum is provided with an inner concentric distributing tube spaced from the drum and composed of a number of spaced sections. Means are provided to adjust the sections in order to vary the width of the spaces and to fix them in place.—H. R. D.

Separating fine material; Apparatus for ——. G. A. Mower and A. Ogilvie. E.P. 179,867, 16.8.21.

Mounted on a vertical spindle are a fan and a series of discs and perforated conical plates. The spindle is coaxial with two concentric cylinders, the outer of which terminates at its lower end in an inverted cone. The inner cylinder terminates at its lower end in an annular grid valve used to regulate the air and operated from the outside of the machine. An inverted conical receiver is attached to the inner edge of this valve, the bottom of the receiver being coupled to a pipe which passes through the outer cone. The material to be separated is fed on to the discs and perforated cones, from which it is discharged by centrifugal force against outer cylindrical and conical plates. The heavier particles ultimately fall into the inner cone and are discharged. The fan situated at the top of the machine draws a current of air through the spaces between the rotating discs and cones and the outer cylinders etc., and discharges into the annulus formed by concentric cylinders, the dust-laden air descending into the space between the inner and outer cones. The dust settles out and is collected at the bottom of the outer cone, the air being drawn again through the grid valve.—S. G. U.

Vapours; Method of dissipating heat in process for extracting —— from gaseous mixtures. G. A. Burrell, O. L. Voress, and V. C. Canter, Assrs. to Gasoline Recovery Corp. U.S.P. 1,382,889, 28.6.21. Appl., 24.1.21.

In the recovery of volatile substances (gasoline, benzol, alcohol, etc.) by absorption in active charcoal, silica gel, etc., considerable heat is developed during absorption, and also the expulsion of the absorbed substance from the absorbent by superheated steam leaves the absorbent considerably warmer than is consistent with efficient absorption.

It is customary to use three absorbers in such a way that one is always being cooled by gas which has been treated in a previous passage. In order to render the process more efficient, it is proposed to increase the heat-absorbing capacity of the gaseous mixture under treatment by mixing with it a gas or gaseous mixture containing only a small proportion of recoverable vapour, or free from such vapour.

High-velocity classifier; Electric —— [for grading particles removed from gases]. C. W. J. Hedberg, Assr. to Research Corp. U.S.P. 1,416,089, 16.5.22. Appl., 26.11.19.

The gas is passed at a high velocity through an electric field, so that the finer particles only are precipitated therein, the larger particles passing on and being separately collected.—J. S. G. T.

Separation of suspended material from gases; Process and apparatus for ——. E. R. Wolcott, Assr. to International Precipitation Co. U.S.P. 1,416,769, 23.5.22. Appl., 30.6.19.

Gas to be treated is moistened and cooled, so that moisture condenses on the particles of suspended material, which are subsequently agglomerated and precipitated by subjecting the gas to the action of an alternating electric field.—J. S. G. T.

Separation of solid or liquid matter held in suspension in gases, employing high-tension electricity; Process of ——. Metallbank u Metallurgische Ges. A.-G. G.P. 348,377, 8.12.19.

Discharge electrodes in the form of smooth rods are disposed at such a distance from the collecting electrodes that the potential of the uniform brush discharge from the former when no deposition has occurred upon them, is higher than the sparking potential between the electrodes on either side. In operation the discharge electrodes are maintained so covered with deposit that the discharge potential necessary to produce a uniform brush discharge is less than the spark potential. By thus utilising the deposited dust to lower the discharge potential it becomes possible to use smooth rods of considerable cross-section as discharge electrodes.—J. S. G. T.

Gases; Disintegrator for use in the wet process for separating dust from ——. E. Wurmbach. G.P. 346,873, 23.12.19.

The amount of surface for the deposition of dust in an apparatus for separating dust from gases by the wet process is increased by the provision of a number of partitions parallel with the outer wall of the spiral separating chamber, whereby the chamber is divided into a number of channels for the passage of the gas.—L. A. C.

Evaporation of stored liquids; Prevention of ——. Prevention of evaporation. (a) F. A. Howard, C. I. Robinson, and J. M. Jennings, (b) F. A. Howard and J. M. Jennings, Assrs. to Standard Oil Co. U.S.P. 1,415,351-2, 9.5.22. Appl., 12.4.20.

Volatile liquids stored in the usual type of tank or container are guarded against loss by evaporation by means of a layer of foam, over the surface of the liquids. Two systems of pipes and apparatus for supplying the foam are described.—F. G. P. R.

Centrifugal oil purifier. M. Leitch, Assr. to The De Laval Separator Co. U.S.P. 1,415,881, 16.5.22. Appl., 22.4.20.

A centrifugal machine having a compound bowl composed of two concentric members, of which the inner one alone has a perforated periphery, is furnished with means for rotating the latter either independently or in conjunction with the outer member.—F. G. P. R.

Separator and dryer. C. J. Wood. U.S.P. 1,416,922, 23.5.22. Appl., 4.6.19.

Granular material is introduced into a separating chamber below which is arranged a valve casing for admitting air to the separator through an inlet port. An outlet port is disposed in the lower part of the casing, and the ports are controlled by a valve so that the separator will discharge through the valve casing and outlet port, when the inlet port in the casing is closed.—J. S. G. T.

Centrifugal separator. C. H. Holmgren. U.S.P. 1,417,064, 23.5.22. Appl., 25.2.21.

The bowl of a centrifugal separator is provided with a number of baffles fitting snugly against the outer wall of the bowl but leaving spaces at or near the axis for the passage of liquid, these spaces decreasing in size from the inlet to the outlet end of the bowl.—B. M. V.

Extractive matters; Process of separating —— from solutions of mixtures of solvents and of recovering the latter. H. Bollmann. U.S.P. 1,417,477, 23.5.22. Appl., 13.1.22.

Mixtures of water and volatile organic liquids which are of constant boiling point and contain extractive matters are separated by distilling the solution so as to obtain a distillate containing the greater part of the water and a part of the solvent mixture, this distillate being separated into two portions of different specific gravity. The remainder of the original mixture is then further distilled, and the distillate mixed with the lighter of the two fractions from the first distillation.—B. M. V.

Lubricant. E.P. 179,344. *See* V.

Filters. E.P. 179,355. *See* XIXb.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Lignin, natural humus material and coal; Autoxidation of —— and the effect of alkali thereon. H. Schrader. Brennstoff-Chem., 1922, 3, 161—167.

Lignin in the presence of $5N$ caustic soda is gradually oxidised at the atmospheric temperature. In presence of oxygen pure lignin lost 9·4% of its weight in 46 hrs., in absence of oxygen 2·6%. The oxidation products recovered from the alkaline solution consisted for the most part of humic acids, together with smaller quantities of succinic and oxalic acids, isophthalic acid (?), pyromellitic or benzenepentacarboxylic acid, and unidentified non-volatile acids soluble in alcohol. Considerable quantities of volatile products (acetic and formic acids, water, and carbon dioxide) were also formed during the oxidation. The oxidation in 8 months proceeded to the extent of about 50% of the original pure lignin. Comparative tests made of the volume of oxygen absorbed in 1000 hrs. by 1 g. of lignin, pine sawdust, lignite, cellulose (filter-paper), and coal, each in contact with $5N$ caustic soda, gave results varying from 82 c.c. of oxygen for lignin down to 6·7 c.c. with coal, the absorptions being in the order mentioned. The bearing of these observations on the theory of the author and F. Fischer that the humic portion of coal is a decomposition product of lignin is discussed, and it is suggested that the action of the caustic soda in the experiments is equivalent to that of lime, ammonia, or bacteria in nature. (*Cf.* J.C.S., July.)—C. I.

Carbonisation of coal; Studies in the ——: the mechanism of coal carbonisation. J. J. Morgan and R. P. Soule. Chem. and Met. Eng., 1922, 26, 1025—1030.

The origin of the aromatic hydrocarbons of ordinary coal tar has been variously attributed to the decomposition of low-temperature distillation products into simple compounds which subsequently undergo pyrogenic syntheses, to the hydrogenation and dealkylation of phenols, and to the dehydrogenation and dealkylation of unsaturated hydrocarbons. A detailed examination of a commercial low-temperature tar in comparison with high-temperature tars (*cf.* page 495 A) shows that pyrogenic syntheses are of secondary importance. The average molecular weights of the liquid products of carbonisation steadily decrease as the temperature of carbonisation rises. The reactions of the phenols are particularly important when distilling coals with an oxygen content equal to that of those used in commercial carbonisation. During the first stage of the decomposition of the primary phenols the side chains of the higher homologues are eliminated, methyl and ethyl groups probably being replaced by hydrogen. Monocyclic aromatic hydrocarbons are mainly derived from phenols and then may be hydrogenated themselves or may participate in pyrogenic syntheses. The quinoline which preponderates among the bases of high-temperature tar is derived from dihydroquinoline. The hydrocarbons in the tars examined result from the dehydrogenation of the naphthenes primarily formed in carbonisation. The formation of di- and tetra-hydro-derivatives constitutes a stable stage in the process as shown by the examination of the tar formed at 600° C. Naphthalene may be formed by hydrogenation of the naphthol derivatives found in low-temperature tar, but, together with other polynuclear aromatic hydrocarbons, mainly results from the decomposition of the polycyclic unsaturated compounds. In view of the preponderance of six-membered ring compounds in low-temperature tar and of the stability of the ring itself, it is suggested that the constitution of the coal substance may be pictured as an aggregate of ring formations. Some of these contain oxygen and possess the characteristics of cellulose degradation products but are regarded as polymerised phenols. Other rings may be held together by paraffinoid groupings, the detachment of which explains the presence of open-chain hydrocarbons in low-temperature tar. Nitrogen and sulphur compounds may appear in analogous configurations.—H. Hg.

Carbonisation; Low versus high temperature —— for the production of smokeless fuel. E. R. Sutcliffe and E. C. Evans. S. Wales Inst. Eng. Gas J., 1922, 158, 631—632.

The combustibility of a coke is not entirely dependent upon the temperature at which it has been prepared but is largely determined by its structure (*cf.* J., 1922, 196 T). Free-burning coke can be prepared at high temperatures from coals which contain little resinous matter and which do not fuse or swell during carbonisation, or from coals which have been briquetted without a binder prior to carbonisation. Such cokes resemble charcoal rather than gas coke in structure. The choice between high and low temperature systems will therefore be governed by economic factors rather than by technical difficulties. The increased yield of coke obtained at lower temperatures is more than counterbalanced by the decreased value of the volatile products. It is possible to obtain high yields of tar and yet carbonise at high temperatures if the temperature is raised slowly.—H. Hg.

Lignites; Comparative researches on the carbonisation of —— on a technical and laboratory scale. K. Bunte and F. Schwarzkopf. Gas u. Wasserfach, 1922, 65, 322—325, 340—343, 355—357.

An earthly lignite from Luckenau was carbonised on a technical scale in retorts and also tested on a laboratory scale, viz., by carbonisation of about 1 kg. in a muffle, by Strache's method of carbonisation in a tube (J., 1911, 1245), using only 0·1—0·2 g., and by Gröppel's tube method of carbonisation using 1 g. of lignite. The figures obtained by the various methods were:—coke: technical scale, 20·0%; muffle method, 23·8%; Strache's method, 28·6%; Gröppel's method, 27·7%; condensed products: technical scale, 35·3%; muffle method, 54·3%; Strache's method, 47·15%; Gröppel's method, 60·3%; gas and loss: technical scale, 44·7%; muffle method, 21·9%; Strache's method, 24·25%; and Gröppel's method, 12·0%. The results obtained by Strache's method, in which air-dried coal is used, and by Gröppel's method, in which the coal is previously dried at 105° C. in a current of nitrogen, are corrected to make them comparable with those obtained by the muffle test and on the technical scale, where the raw lignite is used. There is some uncertainty, however, since some of the moisture undoubtedly leads to the formation of water-gas during carbonisation. In the muffle process, various temperatures were used but in no case did the results correspond with those obtained on a technical scale. By carbonisation in a small tube it was attempted to maintain an even temperature, but by the nature of the process this is not possible, and in consequence the results in different tests are very discordant. The most concordant results are those obtained by the method of Gröppel. All three methods, however, gave results differing widely from those obtained by carbonisation on a technical scale, and no satisfactory conclusion can therefore be drawn from the results obtained by such methods as regards the usefulness of lignites when carbonised at the usual temperatures attained in gas-works.—A. G.

Water-gas generator fuel; Coal and coke mixtures as ——. W. W. Odell. U.S. Bureau of Mines. Tech. Paper 284, 1921. 31 pages.

A decided benefit may be realised by the use of mixtures of coal and coke when operating with a long lay-over period. When the plant is working less than eight hours per day the gas-making capacity is as great as when using coke alone. The fuel consumption per 1000 cub. ft. when employing the blow-run method is less with mixed fuel than when coal alone is used, and gas of a more uniform quality can be obtained. The tar produced from a carburetted water-gas plant using coal or mixtures of coal and coke is less troublesome than that from coke alone as it does not emulsify. The conditions for best results must be worked out for each coal or mixture used, as they vary considerably with the fuel. Special attention is drawn to the necessity of keeping careful watch on the gauges and meters, so that blow-holes or "flues" in the fuel may be quickly detected. The liability to form such is great when mixtures containing over 70% of coal are used and is accentuated by high blast pressure. Trouble may thus be encountered with fuel being blown over into the chequer brickwork. Owing to the tendency of high blast pressures to form blow-holes the amount of air per minute which can be supplied is limited. The use of a fuel spreader is recommended to minimise this tendency. More benefit is derived from an air-purge when coal is used than in the case of coke alone owing to the increase in the methane and illuminants during the progress of the run. Attention is drawn to the danger of damaging the hot valve and generator lid by working with a low fuel bed. It is important to choose the type of oil-spray best adapted for the conditions prevalent. The nozzles should be tested with oil under the conditions of pressure obtaining in actual use.
—A. R. M.

Sulphur and solid paraffins; Probability of reaction between —— in oil-bearing strata. M. A. Rakusin. Petroleum, 1922, 18, 581—582.

Paraffin wax of m.p. 56° C. was heated in a glass retort with sulphur to 190°—205° C. for 18 hrs. The escaping vapours were passed through two U-tubes containing pumice moistened with ammonia and a tube containing calcium chloride. In the first two tubes ammonium sulphide and polysulphides were formed, and the latter were decomposed with hydrochloric acid and the separated sulphur collected. It was found that the amount of sulphur which entered into reaction with the paraffin was about 3% of the weight of the latter. It is concluded that in oil fields which produce both oil free from paraffin wax and oil containing paraffin wax, the oil free from wax should have a smaller sulphur content than the oil containing wax, and this was found to be the case in the Roumanian fields, the respective percentages being 0·042% and 0·112%, and in the Grozny field, where the percentages were 0·212% and 0·782%. For the formation of oil free from paraffin wax from crude oil a temperature of 200° C. would be necessary, which would only be reached at corresponding depths. In the higher and cooler strata the paraffin wax is not attacked by sulphur.—H. M.

Petroleum spirit; Detection of benzene in ——. P. Schwarz. Chem.-Zeit., 1922, **46**, 401.

Five c.c. of the sample is added to 2 c.c. of a mixture of equal vols. of aniline and 95% alcohol; if the petroleum spirit is free from benzene, the aniline separates as a layer, but the presence of as little as 5% of benzene keeps the aniline in solution and the mixture remains clear. The sample may be fractionally distilled, if desired, and the test applied to the fraction having b.p. 80°—110° C.—W. P. S.

Low-temperature carbonisation of coal. Morgan and Soule. *See* III.

Pyrophoric blast-furnace flue-dust. Gilles. *See* X.

Absorption meter for gas analysis. Moser. *See* XXIII.

Patents.

Coal and the like; Washing of ——. A. France. E.P. 179,630, 7.2.21.

Minerals consisting of fine particles, either alone or mixed with larger particles, are separated into constituents of different specific gravities by means of a stream of water in a sloping launder, the heavier material which collects in the lower layers being further sorted by treatment with a liquid of high specific gravity in static columns. The latter liquid may consist of water containing in suspension very fine mineral particles forming the mud which collects in the launder, or may consist of a solution of a solid in water.—A. R. M.

Artificial fuel; Method of producing ——. C. J. Greenstreet. E.P. 179,567, 1.11.20.

Solid fuel, such as coal, peat, lignite, etc., is mixed in a finely powdered state with coal tar, fuel oil, or mineral oil, thickened by means of oleates, stearates, palmitates, or paraffin wax or the like. The mixture can be transported through pipes.
—A. R. M.

Combustible material; Process of making ——. H. S. Mork and G. J. Esselen, jun., Assrs. to A. D. Little, Inc. U.S.P. 1,416,493, 16.5.22. Appl., 10.9.19.

An infusible solidified liquid fuel is prepared by dissolving pyroxylin in a volatile combustible solvent containing a carbonyl group, coagulating this solution in a volatile combustible non-solvent and mixing it with another solution of pyroxylin which is close to the point of coagulation so that the mixture is solidified.—H. Hg.

Burning pulverised fuel in furnaces; Method and apparatus for ——. V. Z. Caracristi. E.P. 179,662, 11.2.21.

Pulverised fuel is allowed to fall into a furnace from burners passing through the furnace roof. Sufficient air for ignition of the fuel is admitted through the burners. Additional unheated air is admitted through a number of ports at different levels in the front wall of the furnace, with the object of preventing intense combustion near the burners and coalescence of the fuel or ash.—H. Hg.

Coke ovens. L. L. Summers. E.P. 179,235, 5.1.21.

An oven with a reciprocating horizontal floor such as is described in E.P. 6504 of 1910 (J., 1911, 274; 1910, 934) is built so that its height is greater than its width. In order to ensure that the frictional resistance between the floor and the material being carbonised is greater than that between the material and the side walls, a vertical longitudinal fin, which may carry lateral flanges, is attached to the floor. Heating flues are provided in the side walls. The material to be coked may be partially distilled and converted into a plastic state in a vertical chamber placed above the charging end of the oven.—H. Hg.

Coking retort oven. J. Becker, Assr. to The Koppers Co. U.S.P. 1,416,322, 16.5.22. Appl., 23.4.20.

A return waste gas main is connected with the regenerators so that if desired waste gas may be directed into some of the in-flow regenerators.
—H. Hg.

Furnace retort. C. H. Smith and E. B. Edwards, Assrs. to International Coal Products Corp. U.S.P. 1,417,113, 23.5.22. Appl., 10.6.19.

A number of combustion chambers are arranged along both sides of a horizontal retort, each chamber extending below the retort. A longitudinal waste gas flue is placed above the retort and the combustion chambers. The connexions are such that gas may be burnt in alternate combustion chambers by means of air preheated in one portion of a regenerator situated underneath the furnace; the waste gases may pass through the remaining chambers and the waste gas flue to the other portion of the regenerator; and the direction of flow may be successively reversed.—H. Hg.

Complete gasification of carbonaceous fuel; Apparatus for ——. J. F. Simpson. E.P. 179,643, 8.2.21.

The apparatus, which may be used either for the production of water-gas from fuel containing no volatile matter, or for the complete gasification of bituminous fuel, consists of a water-gas generator in combination with two regenerators, so arranged that an air blast may be directed through the system in either direction. The regenerators receive their heat in two ways, first from the sensible heat of the gases leaving the generator, and, secondly, from the heat of combustion of a part of the gases which are caused to burn by the admission of the required amount of secondary air. Superimposed upon the generator is a carbonising chamber or retort, which may contain bituminous or non-bituminous fuel. During the period of gas-making, steam is admitted by way of the heated regenerator, through the bed of fuel in the producer, the water-gas thus formed passing up the retort and, in the case of a bituminous fuel, expelling the contained volatile matter. Liquid fuel may, if desired, be admitted into the retort during the "run." The retort is of such construction and of sufficient length that the gas leaving the top is comparatively cool.—A. R. M.

Gas generators for generating low grade gas. J. and O. G. Pierson. E.P. 179,716, 24.2.21.

In a gas producer with an open hearth a mixture of steam and air is supplied both below the grid and to the fuel cone above the grid. The steam is mixed with the air just before entering the fuel bed.—H. Hg.

Gas producer. H. Koppers. G.P. 341,351, 5.12.16.

Gases from a producer shaft enter an adjacent shaft containing fuel through an opening at the bottom of the partition wall between the shafts and pass upwards through the shaft. Non-combustible gases present in the producer gas, together with a mixture of steam and carbon dioxide fed into the stream of gases through openings at the bottom of the partition wall, are converted into combustible gases during passage through the second shaft. The lower ends of both shafts slope towards the partition wall, and means are provided below the opening connecting the two shafts for drawing off the molten slag.—L. A. C.

Gas producer in which the fuel is dried by means of superheated steam. A.-G. für Brennstoffvergasung. G.P. 345,490, 28.1.19. Addn. to 343,048 (J., 1922, 167 A).

In the apparatus described in the chief patent, the connexions between the superheater and drying chamber are connected by pipes provided with valves to the pipe supplying a mixture of steam and air to the producer, so that the proportions of super-heated and saturated steam in the mixture of steam and air can be adjusted as desired.—L. A. C.

Gas producer with separate discharges for the distillation gases and the tar-free producer gas; Recovery of by-products [ammonia] from ——. J. Pintsch, A.-G. G.P. 350,568, 6.10.18.

The distillation gases, cooled to a temperature above that at which moisture is deposited, and the producer gas are scrubbed separately to recover ammonia, and the liquors are united and treated with acid to convert the ammonia into ammonium sulphate.—L. A. C.

Illuminating-gas; Manufacture [purification] of ——. Soc. du Gaz de Paris. E.P. 164,310, 28.4.21. Conv., 4.6.20.

Crude gas is washed with a mixture of a solution of a ferrous salt and milk of lime, whereby hydrocyanic acid is removed as soluble iron-cyanogen compounds and part of the hydrogen sulphide is converted into insoluble iron sulphide. The mixture is then filtered, and the solid material after being exposed to air, is mixed with sawdust, and used for the removal of the hydrogen sulphide remaining in the gas issuing from the washer.—H. Hg.

Gasoline, naphtha, and the like; Process and apparatus for recovering and recondensing ——. G. A. Burrell, C. L. Voress, and V. C. Canter, Assrs. to Gasoline Recovery Corp. U.S.P. 1,382,890, 28.6.21 Appl., 24.1.21.

Gasoline, naphtha, or the like which has been absorbed by active charcoal, silica gel, or the like, is recovered by treating the latter with superheated steam under pressure, the steam and evolved vapours being also condensed under pressure.

Oils; Process of dehydrating heavy ——. F. W. Harris, Assr. to Petroleum Rectifying Co. U.S.P. 1,410,673, 28.3.22. Appl., 31.5.21.

The oil is mixed with a solvent to reduce its viscosity and specific gravity, then treated to remove water, and subsequently freed from the solvent.

[Petroleum oils;] Pressure distillation [of ——*].* E. M. Clark, Assr. to Standard Oil Co. U.S.P. 1,410,797, 28.3.22. Appl., 21.4.19.

A considerable body of the oil is heated under pressure to produce lighter products, and portions of the oil are withdrawn continuously and relieved of pressure in order to distil off the lighter fractions, which are condensed and returned to the main body of oil to undergo further decomposition.

Hydrocarbon oils; Process for treating ——. D. Day. U.S.P. 1,411,237, 28.3.22. Appl., 11.12.19.

Hydrocarbon oils are freed from nitrogenous impurities by treatment with "sludge acid," which is obtained by treating hydrocarbon oils with acid, removing the acid sludge formed, and treating it with steam to separate it into sludge acid and acid tar.

Cracking oils under pressure. C. Ellis, Assr. to Standard Oil Co. U.S.P. 1,415,232, 9.5.22. Appl., 26.11.20.

Oil is passed through a series of narrow tubes heated to 400°—600° C. and from there is led into a tube or chamber of large diameter where exactly the same temperature is maintained. The gaseous products are then led to dephlegmators and fractionally condensed. Superatmospheric pressure is maintained throughout the system, and water, in the form of steam, up to 20—50% by volume of the oil may be fed into the cracking tubes with the oil. Secondary decomposition is said to take place in the large chamber which could not occur in the smaller tubes.—F. G. P. R.

Petroleum-refining apparatus; Continuous ——. C. A. Jouett. U.S.P. 1,415,876, 16.5.22. Appl., 23.9.18.

Preheated oil is sprayed into the top of a vertical cylinder, divided horizontally into a number of chambers, and is heated by means of a concentric flue attached to a furnace stack provided with adjustable ports opposite each chamber. Annular traps are provided at the bottom of each chamber to allow unvaporised oil to flow into the top of the next lower and hotter chamber. Vapour pipes lead from each chamber to superposed dephlegmators provided with run-back pipes to the next lower chamber, and thence through a similar dephlegmator system packed with a solid filtering medium to condensers. Fully refined products are thus produced continuously.—F. G. P. R.

Lubricating oils; Method of producing ——. G. D. Harper. U.S.P. 1,414,695, 2.5.22. Appl., 11.5.18.

Lubricating oils ready for use without purification by acid and alkali may be produced by concentration of a crude naphthene base petroleum oil, such as Franklin heavy oil, to approximately 70% of its original volume and filtration of the residuum.
—F. G. P. R.

Motor fuel. E. W. Stevens, Assr. to Chemical Fuel Co. of America. U.S.P. 1,414,759, 2.5.22. Appl., 9.3.20.

A liquid fuel for internal combustion engines, of the same general character as petrol, is composed of a mixture of a light distillate from petroleum oil, alcohol, a hydrocarbon blending agent, and a small amount of a readily volatile ester of formic acid.
—F. G. P. R.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood-distillation process; Application of electrical precipitation to the ——. L. F. Hawley and H. M. Pier. Chem. and Met. Eng., 1922, **26**, 1031—1033.

A Cottrell precipitator was installed between an experimental wood-distillation retort and a condenser with the object of separating the pitch which normally contaminates the pyroligneous acid. The precipitator was heated to give an outlet gas temperature of about 100° C., under which conditions the precipitated pitch and tar flowed away as a liquid. At higher temperatures a solid pitch was deposited and caused short-circuiting. The outlet vapours were condensed and gave an acid containing 3·3% of soluble tar, whereas the acid normally contained 12—15% of tar. By direct neutralisation of the acid a calcium acetate of 77·8% purity was obtained. Some of the tar was probably formed by polymerisation after the vapours left the precipitator (*cf.* Klason, J., 1915, 707). —H. Hg.

Patents.

Oil containing sulphur; Production of —— and water-glass [from bituminous kieselguhr]. R. Illig. G.P. 346,237, 3.1.19.

Bituminous kieselguhr, either alone or mixed with alkalis or alkali salts, is subjected to dry distillation and heated to fusion point. A mixture of bituminous kieselguhr and sodium sulphate on heating in vertical retorts yields a distillate comprising tar, an aqueous liquid, and crude ichthyol oil; the fused residue in the retort can be treated for the production of water-glass. If bituminous kieselguhr is heated alone, crude ichthyol oil is present in the distillate, and the residue consists of an intimate mixture of carbon and silica suitable for use as an absorbent for nitroglycerin, as a decolorising agent, or as a dyestuff carrier in the production of, *e.g.*, black pigments.—L. A. C.

Incandescent lamp. W. A. Darrah. U.S.P. 1,385,608, 26.7.21. Appl., 23.11.14.

The electrical conductor, *e.g.*, tungsten, in the form of a filament or the like, is suported and embedded in boron nitride, or other infusible, inert insulating material which remains unchanged at temperatures near the boiling point of carbon. The outer surface of the boron nitride or the like may be coated with a substance exhibiting selective radiation, *e.g.*, tungsten or the materials used in the Nernst glower, and the lamp may be filled with an inert gas.

Heat; Production of —— and its application for heating liquids and other purposes. D. La Cœur and C. V. Schou. U.S.P. 1,417,075, 23.5.22. Appl., 30.9.15.

See E.P. 1745 of 1915; J., 1916, 105.

III.—TAR AND TAR PRODUCTS.

Lignite tar industry; Distillation under a high vacuum in the ——. E. Graefe. Brennstoff-Chem., 1922, **3**, 167—171.

The usual practice in the distillation of lignite tar has been to commence with a pressure of 10 cm. of mercury below atmospheric and finish at −40 cm. While this reduction of pressure carries with it the advantages of reduced loss from cracking, saving of time and fuel economy, there is no reason why a higher vacuum should not be used with even greater advantage. This is done in the Brünn-Königsfeld continuous distillation plant designed during the war to treat producer-tar. The small stills used in the lignite tar industry are replaced by a series of 8 horizontal boiler stills of 40 cb. m. capacity, each connected with a preheater. The tar flows through the whole series of 16 units and the greater part of its water content settles out and is drawn off as liquid in the preheaters. Behind each preheater is a condenser so that the distillate may be collected in 16 fractions if desired. The whole is maintained at a vacuum of 68 cm. and the temperatures of the stills range from 200° C. to 320° C. The distillation is completed up to coke in 5-ton cast iron discontinuous stills, and the oil produced by the latter fractionated in another series of continuous stills. In consequence of the low temperature of the distillation the lubricating oil obtained is of high quality.—C. I.

Carbonisation of coal; Studies in the —— : characteristics of low-temperature coal tar. J. J. Morgan and R. P. Soule. Chem. and Met. Eng., 1922, **26**, 923—928, 977—981.

The tar produced during the carbonisation of a bituminous coal containing 35·3% of volatile matter in the primary retorts of the "Carbocoal" process (*cf.* Thurston, J., 1921, 51 T) was examined in detail. The temperature in the retort shell was 730° C. and the volatile products leaving the coal came in contact with surfaces at 600° C. The crude tar was dehydrated by distilling up to 200° C., the light oils being separated from the condensed liquid and returned to the tar. Fractional distillation of the dry tar gave results similar to those obtained during parallel distillations of coke-oven and gas works tars, although the sp. gr. was only 1·0676 and the free carbon content only 0·71%. The pitch obtained was less brittle than that obtained from high-temperature tars. Analysis of the distillates obtained showed that the dry tar yielded 13·7% of phenols, 0·624% of nitrogenous bases, 13·4% of unsaturated hydrocarbons, 2·8% of naphthenes, and 1·6% of paraffins. The high proportion of phenols is characteristic of all low-temperature tars, and from a consideration of the acid content of the fractions of high boiling-point it is concluded that the pitch also contained a large quantity of tar acids. The acids were separated from the distillates by extraction with caustic soda solution and, after purification by benzene extraction and steam distillation, were liberated by the addition of sulphuric acid. Carboxylic acids, if present, were negligible; methoxyl and ethoxyl groups were absent. The mixture of phenols had sp. gr. 1·036, while mixed phenols from coke-oven and gas works tars had sp. gr. 1·044. Phenols from both low- and high-temperature tars were fractionally distilled; there was a smaller yield of low-boiling distillates from the low-temperature phenols, but from the sp. gr. of the distillates it is concluded that the components were similar. Naphthol derivatives were found in the fractions of higher boiling-point of the low-temperature tar phenols. Repeated fractionations followed by nitration and determinations of sp. gr. and freezing point showed that the low-temperature tar phenols contained 4·2% of phenol, 33·4% of cresols, 19·0% of xylenol fraction, 34·8% of higher homologues, and 8·6% of pitch. After separation of acids from the tar distillates determinations were made of the bases present. The results indicated that the pitch probably contained more bases than did the distillates. The mixed bases contained no primary, but about 20% of secondary and 80% of

tertiary bases. The sp. gr. of the mixture was 0·993, while that of the bases from high-temperature tar was 1·060. Bases from both low- and high-temperature tars were fractionally distilled; determinations of the sp. gr. and molecular weights of the distillates indicated, in the case of the low-temperature bases, a greater degree of hydrogenation of the nucleus, the presence of aliphatic side-chains of higher molecular weight, or both. After the removal of the bases the remaining oils were found to contain no alcohols. Hydrogen sulphide was present but carbon bisulphide was absent. Upon exposure there was evidence of polymerisation or oxidation of the hydrocarbons. The sp. gr. of the mixed hydrocarbons was 0·891 while that of the hydrocarbons from high-temperature tar was 1·028. The paraffins and naphthenes were separated from the unsaturated and aromatic hydrocarbons by means of sulphuric acid, and the relative proportions present in the different fractions were estimated by sp. gr. determinations. There was a close similarity to the saturated hydrocarbons obtained in a similar manner from petroleum. Unsaturated and aromatic hydrocarbons were recovered by extraction of the total neutral oil with sulphur dioxide. The oils recovered from the sulphur dioxide were washed with alkali and distilled. From determinations of the sp. gr. and refractive index of each fraction obtained it was shown that there are practically no aromatic hydrocarbons in low-temperature tar and that the unsaturated hydrocarbons are cyclic in character.
—H. Hg.

Phenols; Speed of sulphonation of ——. *I. Effect of temperature and the methyl group.* A. F. Campbell. Chem. Soc. Trans., 1922, **121**, 847—857.

The speed of sulphonation of phenols is strongly influenced by temperature but is independent of the time of reaction and of the concentration. In the experiments the time varied from 1 to 6 hrs. and the quantity of sulphuric acid (96%) from 35 to 65% of the weight of the phenols. The influence of introduction of the methyl group into the phenol molecule on the velocity of sulphonation varies with the relative position of the hydroxyl group and to a certain extent with the temperature. In the ortho or para position to the hydroxyl the methyl group retards the speed of sulphonation at all temperatures from 20° to 80° C. The retarding influence of the ortho group is one-third that of the para at 20° C., but diminishes rapidly up to a constant value at 60° C. At 40° C. the velocity of sulphonation of *o*-cresol is 0·859 of the velocity of sulphonation of phenol. A *m*-methyl group has a maximum effect on the speed of sulphonation at low temperatures, the acceleration gradually diminishing until at temperatures above 65° C. the *m*-methyl group has a retarding influence. A point of equilibrium between the respective effects of the ortho and meta groups and of the meta and para groups is reached at 70° C. and 100° C. respectively, at which temperatures sulphonation of the two isomerides proceeds at the same rate. Above 70° C. the speed of sulphonation of *o*-cresol is the higher. The *p*-methyl group exerts the greatest relative effect, approximately 3·75 times that of the ortho, at low temperature. Phenol is sulphonated at a higher rate than either *o*- or *p*-cresol at all temperatures from 20° to 80° C., and at a lower rate than *m*-cresol at temperatures up to about 65° C. At 20° C. the order of rate of sulphonation (decreasing) is *m*-cresol, phenol, *o*-cresol, *p*-cresol. The influence of a second methyl group ortho to hydroxyl in *p*-cresol is further to retard the velocity of sulphonation. A second *m*-methyl group has a great influence than an *o*-methyl group but in the reverse direction, hence *p*-xylenol is sulphonated at a higher rate than phenol at 40° C.—P. V. M.

Peat and shale tars; Composition of ——. J. Marcusson and M. Picard. Petroleum, 1922, **18**, 637—638.

Peat tar on digesting with ether gave 3% of black insoluble residue consisting of oxyacids and their esters and salts of iron and calcium. The ether solution was freed from bases by treatment with hydrochloric acid, saponified with alcoholic potash solution, and separated by Spitz and Hönig's method (J., 1891, 1039). The unsaponifiable portion contained 8% (on the tar) of solids, which were separated by acetone at −20° C. and had an iodine value of 26·3 and an acetyl value of 31. The saponified solution, when treated with hydrochloric acid, deposited 24·5% of acid substances, and when these were digested with ether 3% of oxyacids remained undissolved. The evaporated ether extract when treated with hot benzine left 8% of insoluble oxyacids of lower m.p. than those insoluble in ether; the 11·5% of matter soluble in benzine consisted of fatty acids of high molecular weight together with phenols. Shale tars tested by a similar method gave, as did peat tars, 16—22% of fatty and oxyacids including those present in the form of calcium salts, and 5% of basic substances.
—H. M.

Patents.

Tars or oils; Process for the continuous distillation of ——. E. Blümner. G.P. 338,846, 23.4.20.

Tar or the like is projected in a finely divided form on to the bottom of a vessel containing a molten metal having a boiling point below the temperature to which the tar is to be heated.
—L. A. C.

Dehydration. Dehydration of pyridine. W. J. Huff, Assr. to The Koppers Co. U.S.P. (A) 1,416,205 and (B) 1,416,206, 16.5.22. Appl., 27.1.21.

(A) Pyridine containing water is dehydrated by distilling off a fraction, which serves as a vehicle to carry off water, removing water from the distillate, returning the pyridine distillate to the still, and repeating these operations until the desired degree of dehydration is attained. (B) A liquid of low boiling point is added to pyridine containing water in less amount than that required to form a binary mixture of constant boiling point, and serves as a vehicle to carry off the water. The mixture is distilled and more of the liquid added till the desired degree of dehydration is attained.
—H. M.

Anthraquinone; Manufacture of ——. Chem. Fabr. Worms A.-G. E.P. 169,145, 1.7.21. Conv., 13.9.20. (*Cf.* E.P. 156,215, 156,538, and 156,540; J., 1922, 407 A.)

In the oxidation of anthracene to anthraquinone by means of air or oxygen in presence of oxides of nitrogen, if the operation is conducted in presence also of a readily soluble reagent which fixes nitric acid, *e.g.*, sodium acetate, no dehydrating agent, such as acetic anhydride, is necessary, nor need an anhydrous solvent be employed. The oxides of nitrogen may be introduced in the form of sodium nitrite, in which case if acetic acid is used as the solvent the requisite sodium acetate will be formed during the reaction, or they may be introduced as fuming nitric acid. The yields of anthraquinone amount to about 95% of the theoretical, and the product has a purity of 97—98%.—G. F. M.

Hydrogenated anthraquinone derivatives; Preparation of ——. Tetralin Ges.m.b.H. G.P. 346,673, 21.7.18.

Tetrahydronaphthalene, or a substitution product, is treated at moderate temperatures with aromatic *o*-dicarboxylic acid anhydrides, *e.g.*, phthalic anhydride, in the presence of aluminium chloride and a diluent such as benzene, and the γ-ketonecarboxylic acids obtained are converted into hydrogenated anthraquinone derivatives by treatment with condensing agents, such as fuming sulphuric acid. Tetrahydronaphthalene and phthalic anhydride in the presence of benzene and aluminium chloride at 60°—70° C. yield β-tetrahydronaphthoyl-*o*-benzoic acid, m.p. 153°—155° C., which on dissolving in cooled fuming sulphuric acid containing 25% of sulphur trioxide, with subsequent heating for 10 mins. to 100° C., yields a mixture of α- and β-tetrahydronaphthanthraquinone of m.p. 135° C. and 211° C. respectively. The isomers are separated by fractional crystallisation, first from benzene and then from acetic acid, in both of which solvents the α-derivative is the more soluble. *ar*-2-Methyltetrahydronaphthalene, b.p. 219°—220° C., prepared by the hydrogenation of β-methylnaphthalene in the presence of a catalyst, on treatment as above yields 3-methyltetrahydro-2.1-naphthanthraquinone, m.p. 119° C. The compounds serve for the manufacture of dyestuffs and drugs.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

-Hydroxybenzanthrone; Derivatives of ——. G. G. Bradshaw and A. G. Perkin. Chem. Soc. Trans., 1922, 121, 911—922.

-Hydroxybenzanthrone or the corresponding hydroxy derivative, when heated under pressure or 8 hrs. at 170°—180° C. in the form of a 32% aste with aqueous sodium hydroxide and dextrose, lycerol, mannitol, lævulose or erythritol (the ast-named being especially effective), yields a fluorescent mixture consisting mainly of a brown amorphous substance together with small quantities of hydroxybenzanthronecarboxylic acid which readily passes into the lactone on heating. The dimethyl derivative of the lactone on oxidation with chromic acid yields methyl-2-methoxyanthraquinone-1-glyoxylate, which passes by hydrolysis and elimination of carbon dioxide into 2-methoxyanthraquinone-1-carboxylic acid. Small amounts of 2.2-dihydroxydianthraquinone and of two compounds, $C_{28}H_{14}O_4$ and $C_{28}H_{18}O_4$, the nature of which is as yet uncertain, are simultaneously produced.—P. V. M.

Red dyestuff; New —— from quinoline. M. Giua. Gazz. Chim. Ital., 1922, 52, I., 349—351.

Condensation of quinoline with either epichlorhydrin or α-dichlorhydrin in presence of alkali hydroxide yields a dark red oily mass from which alcohol extracts a brownish-red compound, $C_{21}H_{18}N_2$, having basic properties. (*Cf.* J.C.S., July.) —T. H. P.

2-p-Dimethylaminostyrylpyridine methiodide. Mills and Pope. *See* XXI.

Patents.

Trisazo dyes; Manufacture of diazotisable ——. J. Dedichen, Assr. to A.-G. für Anilin-Fabr. U.S.P. 1,416,621, 16.5.22. Appl., 15.8.21.

Trisazo dyestuffs having the probable formula:

$$(3)SO_3H.C_6H_4.N_2(1).C_{10}H_6.(4)N_2(1).C_{10}H_5.$$
$$(6)SO_3H.(4)N_2(2).C_{10}H_4.(1)OH.(3)SO_3H.(7)NH_2$$

are prepared from metanilic acid, 1-naphthylamine, 1-naphthylamine-6-(or 7)-sulphonic acid, and 2-amino-8-naphthol-6-sulphonic acid. The products dye cotton reddish-blue shades, which after diazotisation and coupling with β-naphthol or *m*-toluylenediamine are changed to bluish-grey shades. —L. A. C.

Brown colouring matter; Production of —— for adding to margarine. A. L. Mohr, G.m.b.H. G.P. 350,802, 30.5.17.

A brown colouring matter containing butyrin and over 10% of lecithin is prepared by extracting dry casein with hot ehhyl and/or methyl alcohol, and separating the solvent from the extract. —L. A. C.

Gold compounds of Methylene Blue etc. G.P. 347,376. *See* XX.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Cotton fabrics; Detection and estimation of acidity and alkalinity in ——. H. F. Coward and G. M. Wigley. J. Textile Inst. (Trans.), 1922, 13, 121—126.

Neutral cloth was prepared by exhaustively washing two samples of pure bleached cotton fabric, one acid and the other alkaline, until neither fabric was further removed from neutrality than 0·005% of alkali or acid respectively, and it was then shown that fabric which, after de-sizing and washing in water, reacts neutral to methyl red is neutral within 0·005% HCl or its equivalent. Acid is more quickly removed from a fabric by washing it with a solution of common salt than by means of pure water. The method of the British Engineering Standards Association used for testing aeroplane fabric is not suitable for estimating the absolute amount of acid or alkali contained by a fabric, since after washing, cotton fabric can retain 0·05% of its weight of sulphuric acid, and may also react strongly acid to several indicators. In estimating the acidity or alkalinity of a fabric by direct titration at the boiling temperature in the presence of the fabric, using phenolpthalein as indicator, results correct within 0·02% can be obtained. When the acidity is determined by the standard method of acidimetry in which potassium iodide and iodate are used, less accurate though satisfactory results are obtained. Coloured indicators of suitable strength can be used for the approximate estimation of the acidity and alkalinity of fabric by "spotting" on the fabric. Approximate figures for the changes of various coloured indicators are tabulated.—A. J. H.

Animal fibres; New protective agent [against alkalis] for ——. A. Edge. J. Soc. Dyers and Col., 1922, 38, 136—138.

"Protectol A.G.F.A." is a brown, syrupy liquid of neutral reaction, perfectly soluble in water and available in two forms—No. 1, which is precipitated by alkali carbonates, and is intended for use in the presence of alkali hydroxides, and No. 2, which is not precipitated by carbonates or sulphides. These liquids, when used in the proportions of ⅓ to 1½ oz. per gall., protect animal tissues, such as fibres, wool, silk, hair, fur, skin, and leather, from the destructive action of alkaline baths. After the addition of Protectol, wool, union goods, silk, and fur can be subjected to the action of alkaline dyebaths without injury to the animal fibre. Protectol can also be employed in the degumming of silk with caustic soda and in the "liming" of skins with sodium sulphide.—J. F. B.

Cellulose; Behaviour of oxidised ——. E. Knecht and F. P. Thompson. J. Soc. Dyers and Col., 1922, 38, 132—136.

Cotton yarn was treated in the presence of 7·5% sulphuric acid in the cold, with increasing quantities of permanganate up to 1 atomic equivalent of active oxygen. The "copper values" of the oxidised celluloses were determined, and it was found that with the consumption of small proportions of oxygen, up to ¼ atom, the increase of the "copper value" was almost proportional to the oxygen consumed; beyond that the increase in "copper value" was far less rapid. The consumption of ½ atom of oxygen gave a product with copper value of 12·7, and this only rose to 14·0 with the further consumption of ½ atom. Thus it appears that the initial action of the oxidising agent results mainly in the formation of aldehydic or ketonic groups, while the later action is complicated, possibly by the production of carboxylic groups. In order to determine whether the oxidation had taken place at the expense of the hydroxyl groups of the cellulose, esters were prepared under identical conditions from the original and oxidised celluloses. The results of acetylation were inconclusive, both celluloses being esterified to approximately the same extent when sufficient time was allowed. The oxidised cellulose, however, was acetylated rather more slowly than the original, and was considerably hydrolysed to products soluble in water. On nitration the oxidised cellulose showed a very distinct suppression of the hydroxyl activity, yielding nitrates containing only 11·5% of nitrogen with acid mixtures which gave nitrates with 13·4% of nitrogen from the original cotton.—J. F. B.

PATENTS.

Cotton substitutes; Manufacture of ——. B. Possanner von Ehrenthal. E.P. 156,710, 7.1.21. Conv., 24.11.19.

COTTON substitutes suitable for the manufacture of paper, nitrocellulose, etc., and having a uniform strength and staple so that they can be spun by the usual methods, are obtained from various plants and waste such as linseed and hemp seed, straw, jute, reeds, nettles, potato haulm, willow bark, agave, and the like by the following method:—The fibrous material is steeped for 3—6 days in water at 30°—50° C. and allowed to ferment until incrusting substances are partially decomposed. It is then thoroughly washed in water, hydrolysed by treatment for several hours with dilute solutions containing free mineral or organic acids or their acid salts at temperatures not exceeding 40° C., washed free from acid, and afterwards treated with dilute solutions of alkalis, such as caustic soda, sodium carbonate, ammonium compounds, lime, etc., at temperatures not exceeding 50° C. for one or several days, whereby the fibrous material is "opened up" into flexible single fibres which are then thoroughly washed and dried at a low temperature. The fibrous material is more satisfactorily purified if it is subjected, between the operations of hydrolysis and opening-up, to the action of organic solvents, such as ether, benzol, alcohols, carbon bisulphide, acetone, etc.—A. J. H.

Lubricant [for yarns and weaving machines]. L. Minton. E.P. 179,344, 17.2.21.

A LUBRICANT for yarns and fibrous material, as well as for machines employed for weaving such materials, is composed of a mixture of powdered mica and one or more metals, in the form of powder, having lubricating properties similar to those of aluminium (*cf.* E.P. 140,170; J., 1920, 360 A), such as tin, zinc, copper, silver, and platinum. Suitable proportions are equal parts of mica and metal. The mixture may be used dry or combined with an oleaginous base such as tallow, soap or the like to form a paste.—F. G. P. R.

Fibrous material; Process of retting ——. Aktiebolaget Cellulosa. G.P. 342,121, 26.6.18. Conv., 10.5.17.

FIBROUS material is steeped, at a temperature above 90° C., in a liquor of sp. gr. 1·074—1·100, prepared by adding fresh alkali hydroxide to waste liquor from a previous treatment of similar material. The fibres retain their durability and do not darken in colour.—L. A. C.

Fibrous material; Production of —— from plants. Nessel-Anbau-G.m.b.H. G.P. 343,173, 11.6.16. Addn. to 312,381 (J., 1920, 13 A).

AFTER treating plant material by the process described in the chief patent, the liquor is removed from the vessel, and the material is covered with an oil emulsion and boiled for 4 to 24 hrs., whereby the whole of the fibrous content is disintegrated into the elementary fibres.—L. A. C.

Textile fibres; Production of —— from the stems of nettles and other plants. J. Elster. G.P. 343,256, 1.4.19. Addn. to 305,049 (J., 1921, 689 A).

PLANT stems, after treatment with sodium carbonate solution and previous to subsequent treatment as described in the chief patent, are steeped in hot sodium hydroxide solution and then rinsed in water. —L. A. C.

Textile fibres; Production of —— from typha, rushes, and the like. Faserwerke, G.m.b.H. G.P. 343,340, 21.11.19.

TYPHA, rushes, and similar plants are successively boiled with dilute aqueous sodium hydroxide to loosen the fibres, and treated with a hot, strong solution of an alkali hydroxide.—L. A. C.

Textile fibres and half-stuff suitable for paper manufacture; Simultaneous production of —— from reeds and the like. L. B. von Ordody, and B. Schottik und Co. G.P. 345,401, 14.7.18. Addn. to 285,539 (J., 1915, 1138).

REEDS and similar plants are cut up into lengths of about 1 m., and the leaves are removed and bound together with the stems into bundles, and steeped for 21 to 30 days. After drying and again steeping they are bruised, treated for 1—1½ hrs. with an alkali hydroxide solution of 1·0—0·6° B. (sp. gr. 1·007—1·005) under a pressure of 3—4 atm., treated with dilute acid, boiled with water, washed with cold water, and subsequently treated as described in the chief patent.—L. A. C.

Sulphite-cellulose waste liquors and similar solutions; Apparatus for evaporating ——. F. Paschke. G.P. 345,192, 17.1.20.

A CHAMBER provided with a chimney contains a screw conveyor or several superposed screw conveyors in closed casings for transferring the liquor from one part to another. The top casing is provided with an outlet for gases and vapour, and the lowest discharges into a receiver provided with an inlet for the hot gases.—L. A. C.

Drying webs of paper, fabric, or the like; Apparatus for ——. B. F. Sturtevant Co., Assees. of J. O. Ross. E.P. 156,480, 5.1.21. Conv., 8.12.13.

Drying cylinders [for fabrics] and the like. A. Newton. E.P. 179,621, 5.2.21.

Making road surfaces. E.P. 179,480. *See* IX.

Lacquers from nitrocellulose. G.P. 350,973. *See* XIII.

Lacquers from cellulose esters. G.P. 351,228. *See* XIII.

rotective agent for animal fibres. Edge. *See* V.

Patent.

ilk, to be dyed black; Process of weighting or charging ——. A. W. Schmid. U.S.P. 1,417,206, 23.5.22. Appl., 18.2.22.

ILK is weighted by the usual tin-phosphate process, nd then treated in a boiling foam bath containing hæmatein, to which chrysalides boiled up in water have been added.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Potash brines; Evaporation of —— at Deep Springs Valley, California. L. A. Palmer. Chem. and Met. Eng., 1922, 26, 1034—1037.

A NATURAL brine with sp. gr. 1·2896 and containing 7·27% KCl, 11·53% NaCl, 8·88% Na_2SO_4, 5·36% Na_2CO_3, and 0·70% $Na_2B_4O_7$ is pumped into vats and cooled to 10° C. in order to effect the crystallisation of the greater part of the sodium sulphate and some of the sodium carbonate. The remaining brine is mixed with mother liquor from a final crystallisation and treated in a single-effect evaporator heated by steam. The production of foam during distillation is prevented by the introduction of "slop distillate" in order to increase the surface tension of the liquor, and by strips of sheet lead suspended from the steel-work of the evaporator, whereby oxychlorides are formed by electrochemical action and oxidise the organic matter which causes foaming. Sodium chloride, sulphate, and carbonate crystallise in the evaporator and are removed. The enriched liquor containing 22% KCl is passed through a screen into crystallising tanks. As the solution cools potassium chloride and borax crystallise together and are removed from the mother liquor before carbonates and sulphates are deposited. The crystals are heated by steam so that the borax dissolves in the entrained liquor and its own water of crystallisation. The potassium chloride crystals are then separated in a centrifuge and washed with a jet of wet steam.—H. Hg.

Heterogeneous equilibria. The ternary system sodium sulphate — sodium carbonate — water. A. E. Dawkins. Chem. Soc. Trans., 1922, 121, 776—781.

THE isothermal equilibria of the ternary system sodium sulphate, sodium carbonate, water at 19·1° C. are represented on the triangular coordinate system by two liquidus curves intersecting at an invariant point determined by the presence of two series of solid solutions in equilibrium with the solutions represented by the liquidus curves. The composition of the limiting solid solutions in mutual equilibrium at the invariant point is sodium carbonate 2·0% and sodium sulphate 1·9% by weight. The isothermal diagram at 50° C. consists of a three-branched liquidus curve intersecting in two invariant points, and three solidus curves representing three corresponding solid solutions. The compositions of the invariant solutions are:—Sodium sulphate 23·10%, sodium carbonate 10·21%, and sodium sulphate 5·87%, sodium carbonate 28·52% by weight.—P. V. M.

Thiosulphates and polythionates; Occurrence of —— in sulphite-liquor [acid calcium bisulphite solution]. R. Sieber. Zellstoff u. Papier, 1922, 2, 51—56, 106—114.

WHEN sulphite solution is prepared by the use of gases obtained by the complete combustion of sulphur or pyrites, it invariably contains small quantities of thiosulphate. If the gases are carefully filtered before passing into the solution, then the whole of the sulphur can be accounted for as sulphite and sulphate, no thiosulphate being produced. Hence the presence of thiosulphate is attributed to the presence of traces of free sulphur which has sublimed and is carried over by the gases. The results are similar whether the gases are absorbed by lime or by calcium carbonate. When sulphur dioxide containing free sulphur is passed into milk of lime, thiosulphate is produced, which in presence of excess of sulphur dioxide gives rise to polythionates. Of the calcium polythionates, only the trithionate is stable. Gases obtained by the roasting of pyrites may contain small amounts of arsenious oxide and selenium dioxide, and experiments show that arsenious oxide in presence of sublimed sulphur does not prevent the formation of thiosulphate and polythionates. When sublimed sulphur is entirely absent, arsenious oxide only gives rise to small traces of thiosulphate and polythionates. In the case of selenium dioxide, both thiosulphate and polythionates are produced, even in the absence of sublimed sulphur, whilst in the presence of sublimed sulphur the amount of polythionate increases, the thiosulphate only changing slightly. A method is suggested for the estimation of thiosulphate and polythionates in which the thionates are reduced by aluminium and hydrochloric acid in an atmosphere of carbon dioxide, the sulphur being evolved as hydrogen sulphide, and estimated by passing through standard iodine solution. The results obtained are compared with those obtained by a modification of Sander's method (*cf.* J., 1918, 731 A; 1919, 412 A).—J. B. F.

Polythionates; Analysis of ——. A. Kurtenacker and A. Fritsch. Z. anorg. Chem., 1922, 121, 335—343.

TETRATHIONATES in neutral solution react quantitatively with a cyanide to form thiosulphates (J., 1921, 622 A), and trithionates react quantitatively with cyanides in hot alkaline solutions to form sulphites (*cf.* Raschig, J., 1920, 18 A). The latter reaction is incomplete in neutral solutions, and tetrathionates in alkaline solutions give sulphites as well as thiosulphates, hence treatment with cyanide is unsuitable for the estimation of a mixture of the two polythionates. The estimation of a mixture of polythionates by means of a sulphite as recommended by Raschig was found to be unsatisfactory. The method of Riesenfeld and Feld (J., 1922, 55 A) was also tested. In the absence of other polythionates the trithionate reacts quantitatively with copper sulphate, but the estimation is not applicable to mixtures. A tetrathionate boiled for ½ hour with copper sulphate gave a precipitate of copper sulphide and sulphur in proportions corresponding to the decomposition of the tetrathionate as follows, $S_4O_6'' = S_3O_6'' + S$. The authors found, contrary to the results of Riesenfeld and Feld, that tetrathionates are quite stable. A solution showed no decomposition after standing for 14 days, the instability reported being due to impurities.—W. T.

Mother-of-pearl; Attempts at a synthetic manufacture of —— by production of chemical tracery. Clément and Rivière. Comptes rend., 1922, 174, 1353—1356.

IF calcium carbonate is precipitated in the presence of colloidal protein material, such as gelatin, in thin layers, a deposit is obtained having a nacreous structure. The deposit becomes opaque on prolonged drying at 50° C. just as pearl or mother-of-pearl "dies" when strongly dried. These experiments support the accepted views as to the physical and chemical composition of mother-of-pearl and fine pearl.—W. G.

Phosphorescent zinc sulphide. A. A. Guntz. Comptes rend., 1922, **174**, 1356—1358.

The wurtzite and sphalerite forms of zinc sulphide prepared by heating the precipitated sulphide are both phosphorescent. The phosphorescence of the wurtzite form is the more persistent, but in both cases the decrease of luminous intensity is extremely rapid. Under the influence of heat and shock the two varieties are very thermoluminescent and triboluminescent.—W. G.

Minerals; Attack of —— by bacteria. Oxidation of blende. A. Helbronner and W. Rudolfs. Comptes rend., 1922, **174**, 1378—1380.

Certain bacteria (*cf.* Lipman and others, J., 1922, 187 A; E.P. 161,553; J., 1922, 112 A) have been found which are capable of converting blende into zinc sulphate, and the zinc rendered soluble in this manner does not prevent the further action of the bacteria. The oxidation is favoured by the presence of sulphur, and under such conditions the bacteria are able to convert natural zinc silicate or carbonate into sulphate. In minerals containing both zinc and lead as sulphides the zinc is converted into sulphate to the exclusion of the lead, and hence this furnishes a means of separating these two metals. —W. G.

Vanadic acid solutions; Reduction of —— with mercury. L. W. McCay and W. T. Anderson, jun. J. Amer. Chem. Soc., 1922, **44**, 1018—1021. (*Cf.* J., 1922, 140 A.)

When vanadic acid in the presence of sulphuric or hydrochloric acid is vigorously shaken with mercury it is reduced according to the equation $2HVO_3+2Hg+3H_2SO_4=2VOSO_4+Hg_2SO_4+4H_2O$. If the solution before shaking is mixed with a little more sodium chloride than is equivalent to the mercurous sulphate formed the whole of the mercury is precipitated as mercurous chloride and a blue solution left which may be quantitatively titrated with permanganate according to the equation, $10VOSO_4+2KMnO_4+12H_2O=10HVO_3+K_2SO_4+2MnSO_4+7H_2SO_4$. The following method, based on the above reactions, is described for the estimation of vanadic acid. The solution of vanadic acid containing sulphuric acid and the requisite amount of sodium chloride (0·3 g. for each 50 c.c. of *N*/10 permanganate used) is diluted to 100 c.c., and vigorously shaken in a stoppered bottle with 20 c.c. of mercury for 5 mins. The liquid above the grey mercury mixture is decanted into a small beaker and poured through a suction filter. The residue in the bottle is washed four times by decantation, 20 c.c. of water being used for each washing, and the washings are severally decanted into the beaker and then through the filter. The total filtrate is diluted to 250 c.c., heated to 80°—90° C., and titrated with permanganate to the faintest pink. The whole process may be completed in 30 mins.; it gives results which are identical with those obtained by the sulphur dioxide method, and since uranic and arsenic acids are not reduced by mercury it may be employed in the presence of these acids.—J. F. S.

Colloidal ferric hydroxide, aluminium hydroxide, and silicic acid; Centrifugal method for preparing ——. R. Bradfield. J. Amer. Chem. Soc., 1922, **44**, 965—974.

Colloidal ferric hydroxide, aluminium hydroxide, and silicic acid may be prepared from the freshly formed precipitates by removing the excess of precipitating agent by a very thorough washing, which is achieved by means of a centrifuge rotating at 32,500 revs. per min. This method has many advantages over the older methods. The removal of the electrolytes formed on precipitation is more complete; the addition of a peptising agent and its subsequent incomplete removal by either prolonged boiling or dialysis is unnecessary; sols of a more uniform degree of dispersion can be prepared, since particles of similar size and of similar degrees of hydration are deposited in the same zone of the centrifuge bowl; sols of any desired concentration from a semi-gel to the merest trace can be prepared by the addition of water to the more concentrated form, and all concentrations are very stable. Aluminium hydroxide precipitated by ammonia in the presence of an excess of sulphate ions is not irreversible.—J. F. S.

Reduction of oxides by hydrogen. E. Berger. Comptes rend., 1922, **174**, 1341—1343. (*Cf.* J., 1914, 752; Sabatier and Espil, J., 1914, 351.)

From a repetition of previous work, using samples of nickel oxides prepared in different ways, it is shown that the discontinuity in the velocity curves occurs at different stages in the reduction, varying with the sample of oxide used. This discontinuity cannot, therefore, as was previously thought, be explained on the basis of the formation of an intermediate oxide, and doubt is accordingly expressed as to the existence of suboxides of nickel. —W. G.

Scandium; Extraction and purification of —— from thorveitite from Madagascar. P. and G. Urbain. Comptes rend., 1922, **174**, 1310—1313.

The mineral is fused with sodium hydroxide and the residue left after extracting the melt with water is dissolved in the smallest possible quantity of sulphuric acid. From this solution the rare earths are precipitated as fluorides by the addition of an excess of hydrofluoric acid. The fluorides are decomposed by sulphuric acid, and scandium bisulphate crystallises out on concentrating the solution. The sulphates are converted into nitrates by way of the hydroxides and the solution of nitrates is concentrated on a water bath until it is free from excess acid. To the concentrated solution an excess of powdered potassium sulphate is added until the solution is saturated with this salt. After three days the double scandium potassium sulphate is filtered off and washed with a saturated solution of potassium sulphate. Any scandium remaining in the mother liquors is reprecipitated as hydroxide and passed through the same process. The double sulphate may be dissolved in aqueous ammonium carbonate and from the solution, on warming, scandium hydroxycarbonate is precipitated. The residue of the scandium in the mother liquors may be recovered by conversion into its acetylacetonate, which is soluble in chloroform and sublimes when heated in a vacuum at 200° C.—W. G.

Platinum; Mode of action of —— in oxygen-hydrogen catalysis and the application of titanium sulphate for the control of the course of the change. K. A. Hofmann. Ber., 1922, **55**, 1265—1274.

Sensible quantities of hydrogen peroxide are produced in the surrounding acid during the catalysis of dissolved molecular oxygen and activated hydrogen at platinum surfaces only when the reducing power of the hydrogen-platinum electrode is abnormally reduced, when the liquid surrounding the pole contains large amounts of dissolved oxygen, and when the pole is as free as possible from oxides of platinum. It is highly probable that the hydrogen-oxygen catalysis proceeds normally in two stages $O_2+2H=H_2O_2$ and $H_2O_2+2H=2H_2O$. The velocity of the second action at an tive platinum surface is, however, so great that drogen peroxide does not escape into the rrounding liquid. A specific reducing action vards a third substance of hydrogen peroxide, iich is liberated at the best only in minute traces, not to be expected under any circumstances. irther, the reduction potential of hydrogen roxide is much less than the potential of drogen activated at a platinum surface. In eparative or other work in which reductions are be effected with activated hydrogen, the use of id titanium sulphate is recommended for in- ating the conditions favourable to maximum luction or for controlling the course of the ange, since the activity of the system is readily own by the formation of the characteristic violet-own solutions of the sulphate of trivalent anium. In addition, it is to be expected that e reduced titanium will both accelerate and gulate the reducing action, since reduced anium solutions have been frequently successfully ilised as reducing agents.—H. W.

Patents.

lphuric acid; Process for distilling ——. Chem. Fabr. Weissenstein Ges. E.P. 163,685, 23.3.21. Conv., 21.5.20.

RE sulphuric acid is obtained by distillation of hnical sulphuric acid by using as heating bodies ctrical resistances disposed above the surface of e acid in a cylindrical stoneware pot. The top yer of the acid is thus heated by radiation so that aporation proceeds only on the surface, and it is t necessary to heat to boiling temperature the ole of the acid contained in the pot. In addition platinum, the resistances may be made of terials which are not acid-proof, *e.g.*, nickelin or n, without any formation of sulphur dioxide by composition of the sulphuric acid vapour.
—H. R. D.

ydrochloric acid; Method of making ——. C. P. Townsend, Assr. to Hooker Electrochemical Co. U.S.P. 1,414,762, 2.5.22. Appl., 1.3.20.

BODY of hydrogen is confined in a closed system to hich chlorine is suplied at a substantially constant te. Combination of the two gases is effected and e resulting hydrochloric acid withdrawn from the stem. The desired pressure within the apparatus maintained by regulating the supply of hydrogen.
—F. G. P. R.

mmonia; Recovery of —— from peat and the like. P. Brat. E.P. 159,194, 17.2.21. Conv., 18.2.20. (*Cf.* E.P. 157,745–6 and 159,193; J., 1922, 371 A, 462 A.)

HE material is subjected to a pressure of at least atm. at a temperature of 170°—200° C., in the resence of water and one or other of the following asic substances:—barium, strontium, or mag- esium oxide, alumina, or alkali aluminate. A hydrocarbon" having a high boiling point, such as tch, is added to the residue and after vaporising e water the hydrocarbon contained in the peat is covered by distillation at 200°—700° C.—H. R. D.

mmonia; Process for separation of —— from the gaseous mixture obtained in the synthetic production of ammonia from nitrogen and hydrogen. Metallbank und Metallurgische Ges. A.-G. G.P. 343,320, 15.8.14.

HE ammonia is obtained in the form of a mist or g, *e.g.*, by conversion into an ammonium salt, and then separated by electrical precipitation.
—H. R. D.

Ammonium sulphate and other salts; Apparatus for drying ——. J. B. Hansford. E.P. 179,723, 1.3.21.

THE material to be dried is alternately spread by centrifugal force over a heated tray rotating on a vertical shaft, and turned over and piled into heaps by the action of plough-shaped scrapers. By means of rollers, the load on which can be varied, the crystals are subjected to a crushing action. The dried material is ejected from the tray by increasing its speed, thus causing the material to fall over the edge of the tray into an annular receptacle below.
—H. R. D.

Ammonium chloride; Process of recovering —— from solution. N. T. Bacon, Assr. to The Solvay Process Co. U.S.P. 1,416,772, 23.5.22. Appl., 27.12.19.

SOLUTIONS of ammonium chloride are evaporated so as to precipitate ammonium chloride, free ammonia being maintained in the solution.—J. S. G. T.

Calcium nitrate; Process for manufacture of ——. Aluminium-Industrie A.-G. E.P. 163,330, 5.5.21. Conv., 19.5.20.

NITRIC acid obtained from the nitrogen of the air is concentrated to a strength of 90—95% monohydrate and mixed continuously with powdered limestone, *e.g.*, 13 pts. by weight of acid with 11—12 pts. of limestone, according to the purity of the latter. By maintaining the temperature at 60°—80° C. the product obtained leaves the apparatus in a pasty form and hardens on cooling; it contains 75—80% of pure calcium nitrate.—H. R. D.

Sodium cyanide; Process for production of ——. Deutsche Gold- und Silber-Scheide-Anstalt, vorm. Rössler. E.P. 164,719, 22.4.21. Conv., 10.6.20.

SOLUTIONS containing sodium cyanide and sodium chloride, as obtained, for example, in the production of sodium cyanide from calcium cyanamide, are cocentrated, with or without the addition of more sodium cyanide, until saturated with cyanide, whereupon the bulk of the sodium chloride is deposited leaving a solution which can be used as such or treated for the recovery of solid sodium cyanide.—H. R. D.

Slate; Treatment of —— [for recovery of potassium and aluminium salts]. C. R. Hayward and H. M. Schleicher, Assrs. to The American Metal Co., Ltd. U.S.P. 1,415,346, 9.5.22. Appl., 4.3.20.

POTASSIFEROUS slate is treated with sulphuric acid at an elevated temperature, the soluble sulphates thus formed are leached out with water, and potassium alum recovered from the solution by crystallisation.—F. G. P. R.

Sulphur dioxide; Process for enriching metallurgical gases containing ——. G. C. Howard, Assr. to American Smelting and Refining Co. U.S.P. 1,417,066, 23.5.22. Appl., 29.11.18.

FURNACE gases containing a relatively low proportion of sulphur dioxide are mixed with sulphur dioxide expelled from an aqueous solution.
—B. M. V.

Sulphur dioxide; Process for recovering —— from waste metallurgical gases. G. C. Howard, Assr. to American Smelting and Refining Co. U.S.P. 1,417,067, 23.5.22. Appl., 6.3.19.

A SOLUTION containing sulphur dioxide is passed counter current through a mixture of sulphur dioxide gas and water vapour, and the sulphur dioxide subsequently recovered from the solution.
—B. M. V.

Sodium carbonate sulphate; Process of recovering —— from saline waters. G. B. Burnham. U.S.P. 1,417,139, 23.5.22. Appl., 30.6.19.

Searles Lake brine is slowly evaporated until saturated with sodium carbonate sulphate, which crystallises out on continuing the evaporation. —H. R. D.

Sulphur; Recovery of —— from gases [containing hydrogen sulphide]. H. Frischer. G.P. 350,271, 26.11.19.

Gases containing hydrogen sulphide, either alone or mixed with oxygen, are passed through strongly acid solutions of cupric salts capable of reduction by hydrogen sulphide. The formation of sulphur may be accelerated by the addition of salts, *e.g.*, alkaline-earth salts, which are not attacked by hydrogen sulphide.—L. A. C.

Sulphur; Recovery of —— from gases. Hinselmann, Koksofenbauges. m.b.H. G.P. 350,272, 17.9.20.

Material for removing sulphur from gases is kept in motion and in suspension in the gas during the process and during subsequent regeneration by treatment with air.—L. A. C.

Hydrogen sulphide; Removal of —— from gases. Ges. für Kohlentechnik m.b.H. G.P. 350,325, 25.3.20.

Gases are scrubbed with ammoniacal solutions of copper salts, and the sulphides produced in the liquor are oxidised at normal temperature to sulphates by treatment under pressure with gases containing oxygen.—L. A. C.

Percarbonates and perborates; Electrolytic process of manufacture of —— from solutions of alkali carbonates and borates. Deutsche Gold- u. Silber-Scheide-Anstalt, vorm. Rössler. G.P. 350,986, 25.3.19.

Substances, such as fluorides or perchlorates, which increase the anode potential, are added to the electrolyte.—J. S. G. T.

Potassium salts; Process and apparatus for manufacturing —— of varying grain size by cooling hot liquors in vacuo. Maschinenbau A.-G. Balcke. G.P. 351,281, 25.2.19.

Hot stagnant liquor is cooled in shallow vessels, and the pressure in the cooling chamber is gradually reduced to the highest vacuum attained. The period taken in reducing to the highest vacuum is controlled by a throttle valve or similar device disposed between the cooling chamber and the condenser employed, and is determined according to the size of crystal to be produced.—J. S. G. T.

Nitrous gases; Manufacture of concentrated ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 156,799, 7.1.21. Conv., 6.10.15.

See U.S.P. 1,291,909 of 1919; J., 1919, 285 A.

Nitric acid; Process of converting nitrous gases into concentrated ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 156,800, 7.1.21. Conv., 22.5.15.

See U.S.P. 1,197,295 of 1916; J., 1916, 1260.

Aluminium chloride; Production of ——. Armour Fertilizer Works, Assees. of E. C. Baum and D. O. Jones. E.P. 160,759, 11.2.21. Conv., 24.3.20.

See U.S.P. 1,372,332 of 1921; J., 1921, 346 A.

Sulphur; Process for making —— from sulphur dioxide. G. C. Howard, Assr. to The American Smelting and Refining Co. U.S.P. 1,417,068, 23.5.22. Appl., 9.9.18. Renewed 28.11.21.

See E.P. 144,306 of 1920; J., 1921, 735 A.

Separating solids by crystallisation. E.P. 179,287. *See* I.

Water-glass. G.P. 346,237. *See* IIB.

Lime kiln. U.S.P. 1,416,657. *See* IX.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass composition. H. T. Bellamy and B. T. Sweely Assrs. to Western Electric Co. U.S.P. 1,415,980, 16.5.22. Appl., 20.3.20.

A **binder** for compositions of high resistance is made of a non-electrolytic glass composed of barium and calcium silicates and borates.—A. B. S.

Silica bricks; Manufacture of ——. H. Koppers. G.P. 345,949, 17.4.20.

Impure quartzite rock and "crater cement" are finely ground with water, and the mixture made into bricks which have a high silica content. —A. R. P.

Bauxite; Manufacture of objects of dense structure from ——. Dynamidon-Werke Engelhorn und Co. G.P. 346,944, 24.10.15.

Burnt bauxite in a finely-ground condition is moulded into the desired shape and the object burnt in a reducing atmosphere. A portion of the burnt bauxite may be replaced by finely-ground raw bauxite.

Enamels, glazes and like substances; Coating heat-resisting articles by spraying with ——. N. Meurer. E.P. 179,216, 27.11.20.

Articles are glazed or enamelled by spraying them with a powdered material, which is forced by means of gases under pressure through a flame which melts the powder and raises the temperature of that part of the article on to which the spray impinges to the melting point of the enamel or glaze. The spraying device consists of a container for the powder, an arrangement resembling a blowpipe, and pipes which deliver compressed oxygen or air into the container, stirring up the powder and then carrying it downward through other tubes to the flame extending from the nozzle of the blowpipe, and so on to the articles to be coated.—A. B. S.

Enamel for coating the surfaces of steam-engines liable to corrosion. H. Willmer. G.P. 350,770, 27.10.20.

An enamel which is not decomposed by steam contains either no alkalis, or only such as are introduced by the felspar or cryolite used.—L. A. C.

Tungsten or molybdenum carbide; Process for making blocks of any form or desired size from —— or from a mixture of this carbide for tools and articles of all kinds. Process for the manufacture of pieces of tungsten or molybdenum carbide of any desired size. Lohmann-Metall G.m.b.H., formerly Voigtländer und Lohmann Metall Fabrikations Ges. E.P. 157,747 and 157,750, 10.1.21. Conv., 2.1.14 and 16.4.14.

See G.P. 289,066 and 286,184; J., 1916, 423; 1915, 1250.

IX.—BUILDING MATERIALS.

Patents.

Mortar, cement, concrete and the like; Process for rendering —— suitable for the execution, in a durable and reliable manner, of waterproofing, hydraulic and like work, such as preventing water from percolating through walls and the like. K. Winkler. E.P. 167,138, 1.2.21. Conv., 26.7.20.

Mortar, cement, or concrete is gauged with a solution of calcium chloride of 26° B. (sp. gr. 1·22) instead of with water. A small proportion of one or more of the following may also be added: strontium, potassium, and manganous chlorides, calcium, strontium, and magnesium nitrates, manganese dioxide, barium peroxide, chromic oxide, antimony oxide, butter of antimony, manganese borate, sugar, coal, cinders, calcspar, felspar, bauxite, fluorspar. A cement so treated begins to set in 2—5 mins., and is hard within half an hour. Its resistance to compression after 3 days is equal to that of ordinary cement after 20 days and continues to increase. Its resistance to bending is about double that of ordinary cement. Its constancy of volume is exceptional, and it is completely waterproof.—A. B. S.

Rotary [cement] furnaces. S. B. Newberry. E.P. 179,272, 31.1.21.

A rotary kiln is provided with an inner cylinder of refractory material, which is attached to and rotates with the outer cylinder. The inner cylinder may extend about half-way along the outer cylinder, and beyond it through a chamber at the base of the chimney. The material to be heated passes through the inner cylinder, and the hot kiln gases pass through the annular space between the cylinders so as to preheat the contents of the inner cylinder. The gases and volatile matter in the inner cylinder are drawn out by means of a fan, and any useful products in them may be recovered. The object of the device is to enable a mixture of fuel and cement material or fireclay to be burned in a rotary kiln, and to recover any condensable products, particularly oil and ammonia. A supplementary supply of fuel can be used at the discharge end of the kiln.—A. B. S.

[Lime] kiln. R. K. Meade. U.S.P. 1,416,657, 16.5.22. Appl., 23.6.21.

A shaft kiln for burning lime or the like is provided with a stoking grate having rocking sections, a drop bar for operating them, and a hopper for supplying fuel to the grate. The furnace is closed normally and during stoking to prevent the admission of an excess of air.—A. B. S.

Road surfaces; Process for making ——. A. Miller. E.P. 179,480, 3.9.21.

Roads are sprayed with sulphite-cellulose waste liquor of 60°—70° Balling (sp. gr. 1·29—1·51), and allowed to dry; a thin layer of tar is then applied and rolled in. The process may be repeated several times.—A. B. S.

Slag; Method of obtaining granular ——. W. Schumacher. U.S.P. 1,416,069, 16.5.22. Appl., 29.3.12.

A granular slag substantially free from water is made by applying water to the surface of the slag as it issues from the furnace, and separating the water from the slag before the latter becomes cool enough to permit the water to exist in liquid form adjacent to its surface. The hot slag is then passed into a receptacle and cooled.—A. B. S.

Wood; Process for seasoning ——. A. O. Crail. U.S.P. 1,416,269, 16.5.22. Appl., 26.11.20.

The wood is boiled in a 5% solution of common salt for 6 hrs. and then transferred immediately to a kiln where it is heated for 42 hrs. at 250° F. (120° C.).—A. R. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron-carbon-oxygen and iron-hydrogen-oxygen; Equilibria in the systems —— and the free energies of the oxides of iron. E. D. Eastman. J. Amer. Chem. Soc., 1922, 44, 975—998.

Ferric oxide and ferrosoferric oxide at 1100° C. and above form a continuous series of solid solutions, though there are indications that below 1000° C. they may not be soluble in each other in all proportions. Ferrosoferric oxide and ferrous oxide up to 1100° C., at least, do not form a series of solid solutions though they do dissolve in each other to a limited extent. Ferrous oxide appears to be soluble in iron to the extent of 20—25 mol.% (6—8% of oxygen), though metallic iron is not appreciably soluble in the oxide. Ferrous oxide is unstable with respect to ferrosoferric oxide and iron below about 565° C., and ferrosoferric oxide shows an inversion point in the same region. When carbon monoxide reacts with pure iron in a closed tube above 500° C., carbon is not ordinarily deposited as a separate phase. At temperatures above 800° C. a trivariant equilibrium with iron containing dissolved carbon or carbide as the solid phase may be established, or one in which the solid phase contains dissolved oxygen as well as carbon, and the gas is richer in carbon dioxide than in the former case. With a stream of carbon monoxide acting on iron in the vicinity of 650° C. separate phases consisting of carbon, ferrous oxide, and iron containing dissolved oxygen and carbon (or carbide) are probably formed. At higher temperatures the oxide and separate carbon phases do not appear, and the amount of dissolved carbon decreases. Carbon dioxide acting on iron in a closed tube probably produces a trivariant system. At temperatures near 600° C. and lower, carbon is present in the solid phase, decreasing in amount as the temperature is increased. —J. F. S.

Cast iron; Estimation of phosphorus in ——. F. Graziani und L. Losana. Giorn. Chim. Ind. Appl., 1922, 4, 148—153.

The most exact method of estimating phosphorus in cast iron consists in weighing it as magnesium pyrophosphate and this should always be used for the purposes of accurate control. For ordinary routine work, use may be made of the lead molybdate method, which is accurate and rapid; good results are obtainable also by either weighing as ammonium phosphomolybdate or converting the latter into phosphomolybdic anhydride by calcining at a temperature not exceeding 500° C. The alkalimetric method, which is based on titration of ammonium phosphomolybdate with sodium hydroxide solution, is applicable to cast irons of all types and is rapid and yields satisfactory results. When the percentage of phosphorus in the metal is less than 0·5, use may be made of the colorimetric method of Namias based on the stable blue coloration obtained when ammonium phosphomolybdate is treated with hot sodium thiosulphate solution. If a high degree of accuracy is not desired and if the proportion of phosphorus present does not exceed 0·25%, Jüptner's method of centrifuging the liquid containing the precipitated ammonium phosphomolybdate in a suitable tube and measuring the volume of the precipitate may be used.—T. H. P.

Chromium and nickel in steel; Proposed method of determining the ——. F. Simion. Chem.-Zeit., 1922, **46**, 504.

The following method is suggested for separating the chromium and nickel from a nickel-chromium steel. 2 g. of the turnings is dissolved in *aqua regia*, and the solution is neutralised and poured into an excess of caustic soda solution containing hydrogen peroxide or sodium peroxide. After boiling to convert the chromium salts into chromate and destroy excess of peroxide, the precipitate is collected on a suction filter, well washed, rinsed back into the original beaker, and digested with ammonia and ammonium carbonate to dissolve the nickel leaving the iron insoluble. The chromate in the first and the nickel in the second filtrate are determined by any convenient method.—A. R. P.

Chromium-steel; Heat treatment of special steels, especially ——. E. Maurer and R. Hohage. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1921, **2**, 91—105. Chem. Zentr., 1922, **93**, II., 1129—1130.

In the heat treatment of chromium steels, for a given rate of cooling, the ageing temperature is lower the higher the quenching temperature. Tests carried out on steels containing 1—3% Cr and 0·25—0·52% C show that the tensile strength of the alloy quenched from 850° C. depends to a greater extent on the carbon than on the chromium content. The proportion of pearlite increases with the percentage of carbon, whilst chromium causes the larger ferrite and pearlite complexes to coalesce and the metal then has a uniform fine-grained structure which, however, does not always result in high elastic limit and resistance to shock compared with the tensile strength, owing to either too low a temperature, or total lack, of ageing. Determination of the change point and the effect of hardening at different temperatures on the structure and properties showed that quenching from an excessively high temperature did not have the same deleterious effect on chromium-steels as on other tool steels. The bad effect of too high a temperature of forging on the latter may be overcome by a second hardening operation, whereas the structure of a constructional steel, especially if its tensile strength is high, is ruined by forging at too high a temperature. The most useful steel in the above range is that containing 0·4% C and 1·8% Cr. In the notched bar impact tests it was found that with a definite amount of carbon an increase of chromium reduces the toughness of the metal and *vice versâ*. Temper-brittleness is due to the state of the carbide present, material quenched from above 650° C. showing a higher maximum magnetic permeability than that subsequently annealed at 550° C., and it is therefore suggested that there are two forms of the carbide, one stable above 650° C., which is converted into the other normal form by prolonged annealing at 500°—550° C. No difference in the two structures could be discerned, but the grain boundaries of slowly cooled alloys developed more rapidly on deep etching than those of quenched alloys.—A. R. P.

Zinc; Electrolytic extraction of ——. L. Cambi. Giorn. Chim. Ind. Appl., 1922, **4**, 133—147.

Descriptions are given of the various processes for the electrolytic extraction of zinc and of the plants erected, especially in America, for working them, the results obtained being compared with those of the ordinary smelting method. Works experience gained in Italy shows that most of the Italian zinc ores are suitable for electrolytic treatment, the sulphate process giving the best results.—T. H. P.

[*Copper and brass;*] *Relation between the compression force and reduction in height* [*of* ——]. F. Doerinckel. Z. Metallk., 1922, **14**, 189—194.

The relation between the compression force and the reduction in height of test-pieces of copper and various brasses has been determined for temperatures between 0° and 700° C., and the results plotted. In every case up to a reduction of 60% in the height the curve is a straight line; after this it becomes curved convex to the axis of height reduction. The author discusses the subject from a theoretical point of view and evolves a formula for calculating the pressure required to produce any reduction in height, which gives sufficiently close results for practical work.—A. R. P.

Aluminium alloys; Use of molybdenum for improving the properties of ——. H. Reimann. Z. Metallk., 1922, **14**, 195—204.

In continuation of earlier work (J., 1922, 331 A) the author has investigated the effect of small additions of molybdenum to commercial aluminium alloys containing copper, zinc, magnesium, or nickel. Up to 1% Mo has very little effect on the hardness of alloys with the last three metals, but in the case of copper-aluminium alloys containing up to 3% Cu the addition of molybdenum increases the hardness up to 0·7% Mo, then decreases it. The effect of molybdenum on the resistance to shock is not very marked and depends to a great extent on the nature and quantity of the other alloying metal, while no appreciable improvement was made in the tensile strength or ductility of any of the alloys by up to 1% Mo. In all cases the microstructure of the alloys revealed characteristic needles of the peritectic Al-Mo crystals more or less finely disseminated throughout the alloy. Molybdenum does not reduce the temperature range of solidification, the amount of piping, or the tendency of the third constituent to segregate, and, in general, the results obtained by the addition of molybdenum to aluminium alloys do not seem to justify the extra cost.—A. R. P.

Nickel; Analysis of technical ——. K. Breisch and K. Chalupny. Chem.-Zeit., 1922, **46**, 481—482.

10 g. of the metal is dissolved in nitric acid, the solution evaporated repeatedly with hydrochloric acid to dryness on the water bath, the silica filtered off, ignited, and weighed, and the filtrate diluted to 750 c.c. and treated with barium chloride for the determination of the sulphur. A second 10 g. of the metal is dissolved in nitric acid and the solution electrolysed at 4—4·5 volts for 15 mins. with rotating electrodes, whereby copper is obtained on the cathode and lead as peroxide on the anode. Iron and manganese are determined by dissolving 5 g. of the sample in nitric acid and treating the solution with ammonia and bromine. The precipitate, which contains appreciable amounts of nickel, is dissolved in hydrochloric acid, the solution exactly neutralised with ammonium carbonate, treated with 10 c.c. of 10% ammonium formate solution, diluted to 300—400 c.c., and boiled for 15 mins. The precipitate contains all the iron, which is determined as usual. Hydrogen sulphide is passed through the solution to remove the nickel, and the filtrate is treated with bromine in excess, then with ammonia to precipitate manganese. Oxygen is determined by the loss in weight on ignition in hydrogen, arsenic and antimony by distillation, and zinc as described prevously (J., 1922, 256 A).—A. R. P.

Silver amalgam of the composition, Hg_3Ag_2; Preparation of a —— *by precipitation from a solution of silver nitrate in pyridine.* R. Müller and R. Hönig. Z. anorg. Chem., 1922, **121**, 344—346.

Metallic needles of Hg_3Ag_2 were formed by keeping a drop of mercury in contact with a solution of silver nitrate and cuprous iodide in anhydrous pyridine. Using silver nitrate solution alone, crystals of mercurous nitrate were deposited and a liquid amalgam formed. For the formation of the crystals the addition of an approximately equal amount of cuprous iodide (1:1) is necessary. The addition of a much smaller amount (1:10) causes the precipitation of finely divided black silver, whilst with too large amounts of cuprous iodide (5:1) the drop of mercury changes into a granular powder. Cuprous iodide can be replaced by cerous chloride, the separation of crystals being, however, much slower.—W. T.

Flue-dust; Pyrophoric —— [from iron blast furnaces]. J. W. Gilles. Stahl u. Eisen, 1922, 42, 884—889.

The very finely-divided flue-dust from the dry gas-purifying chambers from iron-smelting furnaces, if exposed to the air while warm, commences to glow and changes colour from light grey to red-brown, at the same time emitting vapour consisting of a mixture of ammonia, carbon dioxide, and cyanogen compounds having a very objectionable odour. The dust is not pyrophoric when quite cold, but is easily ignited with a glowing piece of charcoal, a temperature of 167°—220°C. only being required to initiate glowing, while the highest temperature reached in the combustion is about 600° C., each gram of dust emitting 400—500 cals. A number of samples of pyrophoric and non-pyrophoric dust from various works were analysed in order to ascertain the cause of the phenomenon, but no concordant results were obtained. It, however, appears highly probable that the cause is the presence of a large amount of manganese oxide (MnO) which in the finely divided form glows when heated above 180° C. in air, forming the oxide Mn_3O_4. The glowing is increased by the combustion of other substances, *e.g.*, carbon and sulphides of iron or zinc, when the temperature rises high enough.—A. R. P.

Attack of minerals by bacteria. Helbronner and Rudolfs. *See* VII.

Patents.

[Iron;] Electrolytic methods of depositing metals [especially ——]. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 179,675, 14.2.21.

Sound homogeneous ribbons of electrolytic iron, as thin as 0·00025 in., may be obtained by electrodeposition from a bath of ferrous chloride or other salt by the use of an iron anode and a cathode consisting essentially of a revolving wheel partly immersed in the electrolyte, the rim of the wheel, on which the iron is deposited, being formed of a narrow band of tungsten or molybdenum or of an alloy of these elements with one another, or with other elements. The deposit does not adhere to the cathode, and is readily stripped therefrom as it leaves the bath.—A. R. P.

Iron and steel; Method of pickling —— in acid baths. O. Vogel. G.P. 350,771, 31.3.20. Addn. to 309,264 (J., 1921, 853 A).

In the process described in the chief patent, organic compounds containing the quinoline nucleus are added to the pickling bath.—L. A. C.

Crucible furnaces [for melting metals]. F. G. Penny. E.P. 179,463, 7.7.21.

A number of melting pits, each provided with a blast pipe, are connected with a corresponding number of preheating pits by flues which gradually expand from the tops of the former to the bottoms of the latter. The final outlet flues from the top of the latter are provided with ejector jets connected with the main blast.—B. M. V.

Furnace [; Crucible ——]. J. A. Gaskill. U.S.P. 1,417,478, 23.5.22. Appl., 28.5.20.

The refractory body of the furnace which contains the crucible is mounted on trunnions and provided with a jacket in which the air for combustion is preheated. The air is admitted tangentially at the bottom of the jacket and passes from the top to a pair of mixing chambers situated on the trunnion shafts outside the bearings, where it is mixed with fuel. The mixture then passes through the hollow trunnions to burner jets and enters the interior of the furnace tangentially. —B. M. V.

Furnaces; Continuous re-heating or annealing ——. Façoneisen-Walzwerk L. Mannstaedt und Co., A.-G., and H. Bansen. E.P. 179,638, 7.2.21.

In continuous annealing furnaces, where the waste gases are removed through a recess in the roof and down through side passages, the hearth is extended beyond the recess so as to form a preheating zone, the roof of which is progressively lower from the recess to the charging door. —B. M. V.

Composite metal articles. British Thomson-Houston Co., Ltd., Assees. of C. Steenstrup. E.P. 158,565, 26.1.21. Conv., 26.1.20.

Two metal parts (*e.g.*, high-speed steel and carbon steel) are joined by a more fusible metal (*e.g.*, copper). The parts are heated in a reducing atmosphere and maintained in such close contact that the joining metal, applied, for example, in the form of wire or ribbon, is practically all used up in forming an alloy with the surfaces to be joined. The parts may be held together under great mechanical pressure and temporarily locally welded, so that the pressure will be maintained on removal of the clamp, before being permanently joined by means of the alloying metal. Composite articles constructed in this manner can be subjected to mechanical working and heat treatment as a whole.—B. M. V.

Metallic ores aid residues containing metallic oxides; Purification of ——. W. H. Dyson and L. Aitchison. E.P. 179,201, 28.10.20 and 27.7.21.

The process described in E.P. 176,428 and 176,729 (J., 1922, 332 A) is extended to cover the recovery of cobalt, manganese, copper, lead, zinc, etc., from their ores. Details of the temperatures necessary in these cases are given.—A. R. P.

[Copper-aluminium] alloys. I. Iytaka, and Mitsubishi Zosen Kaisha, Ltd. E.P. 179,261, 28.1.21.

Non-oxidisable alloys that retain their lustre up to 500° C. and do not corrode in air or sea water consist of 77—97% Cu, 2—11% Al, and 3—12% Sn, or 1—12% Zn, the zinc or tin being present in approximately the same proportion as the aluminium.—A. R. P.

[Iron-aluminium] alloys. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 179,306, 3.2.21.

An alloy that will withstand temperatures of 1200°—1500° C. for long periods without oxidation or scaling consists of 10—15% Al and at least 35% Fe and 30% Ni. Addition of chromium up to a maximum of 5% reduces the grain size and renders the metal harder and tougher.—A. R. P.

Osmium alloys. W. C. Heraeus G.m.b.H. G.P. 350,703, 22.6.19.

Hard alloys highly resistant to chemical action, and suitable for the manufacture of the points of gold pens, compasses, and prisms, contain at least 70% of osmium, another metal of the platinum group, especially iridium, platinum, or palladium, together with 1—10% of a third metal of the platinum group, especially rhodium or ruthenium. —L. A. C.

Zinc alloy. J. Zufall. G.P. 350,704, 4.4.19.

An alloy suitable for use as bearing metal and for the manufacture of ornaments, containing 84·1% Zn, 1·8% Cu, 1·0% Al, 4·9% Sn, and 8·2% Pb, is prepared by melting together 1 pt. of an alloy containing 11 pts. of zinc and 3 pts. of copper, 0·6 pt. of an alloy containing 8 pts. of zinc and 2 pts. of aluminium, 9 pts. of zinc, 0·6 pt. of tin, and 1 pt. of lead.—L. A. C.

Sulphide ores; Method of treating ——. C. J. Reed. U.S.P. 1,415,897, 16.5.22. Appl., 9.6.20.

The ore is heated under non-oxidising conditions to volatilise sulphur, then leached with sulphuric acid, and the metallic sulphate formed is finally converted into metal oxide and sulphur trioxide. —B. M. V.

Ores; Method of concentrating —— [by flotation] Concentration of ores. R. Luckenbach, Assr. to Luckenbach Processes, Inc. U.S.P. 1,417,261—3, 23.5.22. Appl., (A) 31.12.19, (B) 3.1.21, and (C) 13.1.21.

The pulp of finely divided ore and water is agitated with (A) the product of the reaction between a bitumen and an alkali and sufficient acid to render the pulp neutral, (B) the product of the reaction between an alkali and lac, or (C) an alkali and a liquid, normally unsaponifiable resin; and the resulting froth is separated.—A. R. P.

Aluminium; Composition of matter for and method of soldering and welding ——. P. de Clamecy, Assr. to B. F. Sturtevant Co. U.S.P. 1,415,925, 16.5.22. Appl., 8.7.19.

The solder consists of aluminium, tin, silver nitrate, and silver chloride.—B. M. V.

Aluminium; Soldering composition for ——. F. A. Albertus, Assr. to C. S. Flint. U.S.P. 1,416,924, 23.5.22. Appl., 3.12.19.

A solder for aluminium consists of relatively large proportions of tin and zinc, and relatively small proportions of aluminium, antimony, and phosphor-tin, the proportions of antimony and phosphor-tin being less than the proportion of aluminium. —J. S. G. T.

Copper; Method of and apparatus for recovering —— [from solutions of copper sulphate]. H. M. Wilcox, Assr. to F. C. L. D'Aix. U.S.P. 1,416,147, 16.5.22. Appl., 14.7.17.

Strong copper sulphate solution is continuously admitted to the bottom, and spent liquor removed from the top, of a precipitating tank, the precipitated copper being withdrawn from the bottom without stopping the operation.—B. M. V.

Copper; Process and apparatus for extracting —— from slag in reverberating furnaces. P. P. Butler and H. H. Stout, Assrs. to Phelps Dodge Corp. U.S.P. 1,416,262, 16.5.22. Appl., 7.7.19.

The slag is tapped from the smelting chamber of a reverberatory furnace into a second chamber where it is heated to a much higher temperature after addition of a "washing ore."—A. R. P.

Diamagnetic minerals; Process and apparatus for the concentration and separation of ——. W. C. Hall. U.S.P. 1,416,634, 16.5.22. Appl., 4.8.21.

The ground ore is passed through an intensified magnetic field formed between the pole of a stationary electromagnet and a movable magnetic roller, whereby the diamagnetic material in the ore is attracted and becomes attached to the roller. —A. R. P.

Metal or metals and other material [especially graphite]; Production of a mixture containing a ——. G. Ising and H. Borofski. G.P. 351,022, 2.6.20.

Material which does not form alloys with metals, *e.g.*, graphite, is added to a metal or mixture of metals in a semi-liquid, pasty condition, and the mixture is stirred or beaten until the metal content assumes a fine, granular condition, the temperature of the mixture being simultaneously lowered to a point at which the pasty condition is still maintained, but the metallic particles are harder than the added material. The mixture maintains its structure on subsequent treatment in presses or the like.—L. A. C.

Copper-plating metal parts; Process of manufacturing a solution for ——. W. Narr, sen. G.P. 351,251, 22.3.21.

A mass of pure copper or copper scrap is treated for 12—14 days with a solution containing 1¼ pt. of hydrochloric acid to 8¾ pts. of water. The resulting solution is especially suitable for copper-plating iron and steel goods, and the coating is more quickly produced and is more adherent than that afforded by the use of a copper sulphate solution. —J. S. G. T.

Electrolytic apparatus and method [for production of laminæ of electrolytic iron]. C. Dantsizen, Assr. to General Electric Co. U.S.P. 1,416,692, 23.5.22. Appl., 21.5.20.

See E.P. 179,675 of 1921; preceding.

Metallic surfaces; Coloration of ——. T. Rondelli and Q. Sestini, Assrs. to Sestron (Foreign Patents), Ltd. U.S.P. 1,417,413, 23.5.22. Appl., 30.6.20.

See E.P. 164,127 of 1920; J., 1921, 516 A.

Electrical precipitation in wood distillation. Hawley and Pier. *See* IIB.

Patents.

Electric conductors; Method of insulating ——. The British Thomson-Houston Co., Ltd. From The General Electric Co. E.P. 179,460, [illegible]7.21.

Electrical conductors covered with insulating fibrous material, *e.g.* cotton, are passed through a bath of insulating liquid, *e.g.* molten asphalt, maintained at a temperature sufficiently high to eliminate air and moisture from the covering, and then passed through a coagulable oil, preferably China wood (tung) oil, at a temperature high enough to coagulate the oil. The coated wire is finally passed through a finely-divided mineral material, *e.g.* powdered talc, and if desired through a die. Conductors so treated are substantially non-combustible under operating conditions. —J. S. G. T.

Insulating metal particles; **Method of** ——. G. W. Elmen, Assr. to Western Electric Co. U.S.P. 1,383,703, 5.7.21. Appl., 21.1.20.

Iron particles to be used in the manufacture of magnet cores are mixed with sufficient of an oxidising agent, such as water or a weak solution of hydrogen peroxide, to produce a black oxide on the surface, but not enough to convert the particles completely into oxide or to produce a coating of red oxide. The mixture is then heated and agitated in a container at a temperature below that at which the magnetic properties of the metal change, until the desired surface oxidation is effected. The process may also be applied to cobalt, nickel, and alloys.

Platinum anodes [*for electrolysis*]. Deutsche Gold u. Silber-Scheide-Anstalt vorm. Rössler, and O. Liebknecht. E.P. 179,636, 7.2.21.

In electrolytic processes in which active oxygen is evolved at the anode, zinc is used as a stiffening and current-conducting support for the platinum anodes employed. Thus, platinum net or foil may be clamped in a zinc frame or by zinc bars. —J. S. G. T.

Electrolysis; Art of ——. W. E. Bailey. U.S.P. 1,416,929, 23.5.22. Appl., 7.11.21.

The electrolyte flows past one electrode and impinges through a movable nozzle as a jet upon an article forming a second electrode of an electrolytic cell, the electrodes being connected with the appropriate poles of a source of current. Electrolytic action thus occurs at and near the point of impingement of the jet. The method is applicable to the electrodeposition of metals to form patterns or designs.—J. S. G. T.

Batteries; Depolariser for [*alkaline*] *primary* ——. R. C. Benner and H. F. French, Assrs. to National Carbon Co. U.S.P. 1,415,860, 16.5.22. Appl., 22.8.18.

A depolariser for alkaline cells consists of a mixture of cuprous oxide and sulphur.—J. S. G. T.

Storage battery; [*Mixture for use in*] *electric* ——. E. Hacking, Assr. to Electrol Mfg. Co. U.S.P. 1,416,195, 16.5.22. Appl., 30.4.18.

A mixture for use in storage batteries provided with lead plates, consists of sodium silicate, sulphuric acid solution, and a smaller proportion of a liquid hydrocarbon miscible with the other constituents and not oxidised by the acid.—J. S. G. T.

Battery construction. [*Electrolyte for alkaline battery.*] A. L. Muren. U.S.P. 1,416,738, 23.5.22. Appl., 11.1.19.

An alkaline battery electrolyte contains an alkali tungstate.—J. S. G. T.

Storage-battery separator. G. Steerup, Assr. to U.S. Light and Heat Corp. U.S.P. 1,416,761, 23.5.22. Appl., 11.8.19.

Electric current is passed through a mass of conducting material interspersed with non-conducting material and containing a substance which gasifies when the current passes, the whole mass being fused into a coherent block.—J. S. G. T.

Paste [*spongy lead for storage batteries*]; *Method of preparing* ——. C. C. Carpenter, Assr. to U.S. Light and Heat Corp. U.S.P. 1,416,787, 23.5.22. Appl., 19.4.20.

Spongy lead is ground to a definite fineness and treated with sulphuric acid in definite proportion to control the proportions of spongy lead and lead sulphate in the resulting product.—J. S. G. T.

Electric storage batteries; Process of making ——. H. M. Williams, Assr. to Electrol Mfg. Co. U.S.P. 1,417,007, 23.5.22. Appl., 19.8.20.

Lead plates used in storage batteries employing sulphuric acid in a solid filling medium as electrolyte are charged and discharged in a solution of sulphuric acid of customary specific gravity until the specific gravity of the acid in the pores of the plates is approximately 1·200. The free electrolyte is then replaced by a mixture containing, by volume, 1 pt. of liquid sodium silicate, 3 pts. of water, and 5 pts. of sulphuric acid of sp. gr. 1·400. The resulting electrolyte consists of sulphuric acid of sp. gr. approximately 1·200 contained in a gelatinous mass of colloidal silica.—J. S. G. T.

Crucible furnace; Three-phase [*electric*] ——. C. H. Carpenter, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. 1,415,989, 16.5.22. Appl., 22.5.20.

The furnace chamber is surrounded by a resistor, and terminal electrodes are provided in a number of wells placed symmetrically around the chamber, and containing granular conducting material in contact with the resistor.—J. S. G. T.

Electric-furnace linings; Method of preserving ——. H. C. Sicard, Assr. to United States Ferro Alloys Corp. U.S.P. 1,416,584, 16.5.22. Appl., 12.2.20.

A mixture of titaniferous and metallic ores is smelted in a furnace provided with a titanic oxide lining.—J. S. G. T.

Heating element; Electrical ——. P. A. E. Armstrong. U.S.P. 1,416,436, 16.5.22. Appl., 1.5.19. Renewed 1.10.21.

An electrical heating element contains over 4% of chromium and over 0·1% of carbon, the remainder being principally iron.—J. S. G. T.

Ozone; Apparatus for producing ——. H. E. Ellis. U.S.P. 1,417,046, 23.5.22. Appl., 10.12.20.

An auxiliary vessel filled with water is disposed within an outer vessel by means of a flange engaging a flange on the latter. An electrode is disposed within the inner vessel, being suspended from a member extending across its upper end, this member also securing the two vessels together. An electrode is likewise provided in the space between the two vessels near the lower end thereof. Air to be ozonised is forced through the outer vessel. —J. S. G. T.

Electric furnace. H. de Nolly, Assr. to La Soc. Métallurgique du Frayol. U.S.P. 1,417,303, 23.5.22. Appl., 8.4.20.

See E.P. 157,051 of 1920; J., 1921, 225 A.

Electric furnace regulators. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 179,595, 31.1.21.

See also pages (A) 491, *Electric classifier* (U.S.P. 1,416,089); *Electrical separation of suspended material* (U.S.P. 1,416,769 and G.P. 348,377). 502, *Percarbonates and perborates* (G.P. 350,986). 516, *Fodder from straw* (G.P. 351,051).

XII.—FATS; OILS; WAXES.

Corn (maize) oils, obtained by expression and benzol extraction methods; Comparison of ——. A. F. Sievers. Bull. No. 1054, U.S. Dept. of Agric., 11.3.22. 20 pp.

A review of previous investigations on maize oil is given, with a table of physical and chemical constants. The material used was obtained from typical plants making hominy and glucose, the former producing dry-process germs and the latter wet-process germs. The extraction of both germs and oil cake was undertaken. The benzol extraction was carried out by treating 50lb. of ground germs or oil cake in a galvanised iron can with a false bottom. The benzol used distilled completely at 85° C. 90% of the benzol was removed by heating on a steam bath under a partial vacuum, the last portions by passing a current of dry steam into the mixture under reduced pressure. Considerable difficulty was caused by the foaming of the oil during the removal of the solvent. This was most troublesome in the case of the dry-process germs, and is ascribed to the presence of starchy matter. The oils from the dry-process material were somewhat lighter in colour than the other oils, and uniformly lower in free fatty acids. There was no difference between the free fatty acidity of the extracted oil and expressed oil from the dry-process germs. In the case of the oils from the wet-process germs the extracted oils contained more free fatty acids than the expressed oil. All the oils were refined in the same manner with the exception of the extracted oil from the dry-process germ-cake, which required a greater quantity of sodium hydroxide owing to sediment, and all were deodorised by treatment with steam at 225° C. for 2 hrs., under 25 in. vacuum. The expressed oils showed the lowest refining loss. There were no striking differences in the physical and chemical constants of the oils from the two types of germs by the two different methods of extraction. No material difference could be noted in the finished oils from the germs immediately after their preparation, but upon standing some deterioration took place, and this was more noticeable in the extracted oils than in the expressed oils. All oils were sufficiently light in colour for use as salad oils and for cooking purposes. The oils obtained by benzol extraction of the two types of oil-cake were inferior in all respects to the oils from the germs, that from the cake from the wet-process germs being the poorer of the two. —H. C. R.

Liver oil of the tope. A. C. Chapman. Analyst, 1922, 47, 203—204.

Oil obtained from the livers of tope (*Galeus galeus*) has the following characters: Sp. gr. at 15°/15° C., 0·9249; iodine value (Wijs), 152·2; saponif. value, 185·1; n_D^{15} =1·4803; unsaponif. matter, 1·14%; brominated glycerides insoluble in ether, 42·5%. The oil has a pale yellow colour and is used for the dressing of leather and for medicinal purposes. —W. P. S.

Food [fat] analysis; Use of semi-microchemical and microchemical methods in ——. H. Lührig. Pharm. Zentralh., 1922, 63, 218—221, 227—232.

Methods are described for determining various analytical constants of fats and oils, very small quantities of the substance being used for the purpose; *e.g.*, the Reichert-Meissl value is determined on 0·5 g. of fat, the saponif. value on 0·1 g., and the iodine value on 0·03 g. The Polenske value is obtained on the quantity of fat used for the Reichert-Meissl value.—W. P. S.

Fatty acids of rape oil. E. Raymond. Bull. Soc. Chim., 1922, 31, 414—419.

In the mixture of fatty acids obtained by the saponification of a sample of Indian rape oil the author has identified the following fatty acids: erucic acid, linolic or linolenic acids giving soluble bromides, palmitic, oleic, and stearic acids, and small amounts of linolic or linolenic acids giving insoluble bromides.—W. G.

Sativic acid. E. Reinger. Ber. deuts. Pharm. Ges., 1922, 32, 124—131.

The progressive elimination of hydroxyl groups from sativic acid (tetrahydroxystearic acid) prepared by the oxidation of linolic acid was effected by heating the acid with 60% sulphuric acid, whereby 1 mol. of water was eliminated, the unsaturated acid $C_{18}H_{34}O_5$ produced being then converted by hydrogenation into a trihydroxystearic acid. By repeating the operation with this acid a dihydroxy unsaturated acid, $C_{18}H_{34}O_4$, and finally a dihydroxystearic acid were obtained from which a monohydroxy unsaturated acid and finally 12-monohydroxystearic acid were prepared. The constitution of each of the unsaturated acids was determined by an examination of their oxidation products, and that assigned by Eckert (J., 1917, 892), to the original sativic acid was confirmed, namely, $CH_3.(CH_2)_4.[CH(OH)]_2.CH_2.[CH(OH)]_2.(CH_2)_7.CO_2H$. The position of the double bonds in linolic acid follows accordingly. (*Cf.* J.C.S., 1922, i., 623.) —G. F. M.

Soaps; Spontaneous heating of ——. A. Welter. Chem. Umschau, 1922, 29, 151—152.

Powdered or flaked soaps with a low water content prepared wholly or partly from drying or semi-drying oils, show a tendency to rise in temperature. Differences in temperature of 20°—30° C. have been observed between the exterior and interior of quantities of soap flakes stored in wooden chests after passage through the drying machines in the case of soaps prepared from unsaturated fatty acids, whereas there is no difference in temperature when saturated fatty acids have been employed. The zinc oxide often added to the soap to render it opaque and to improve its appearance exerts an anti-catalytic action, and diminishes the rise in temperature. Pure olive oil yields soaps with no tendency to rise in temperature, but cottonseed oil and other semi-drying oils often used to adulterate olive oil have the effect of inducing this tendency in soap prepared from adulterated oil. The author cites a case in which a pile of 500—600 kg. of cold, dry powdered soap prepared from cottonseed oil developed such a rapid rise in temperature that in ½ hr. it was reduced to a black coke-like mass. —L. A. C.

Enzymic synthesis of fat. Spiegel. *See* XVIII.

Patents.

Oils and fats from oily and fatty substances; Process of squeezing —— and device for working such process. O. A. Fankhauser. E.P. 158,844, 2.2.21. Conv., 3.2.20.

The substance, a fluid mass of, *e.g.*, cocoa, is fed continuously under high hydraulic pressure into one end of a filter chamber, the oil or fat is expelled through the filter, and the spent material is expelled from the other end of the chamber by the same hydraulic pressure. The filter is formed of small wooden blocks, with the fibres disposed radially, mounted around a hollow piston provided with radial holes, the inner surface of the blocks being formed with annular and longitudinal grooves. The piston is moved to close the outlet end of the chamber during the expulsion of the oil etc., and to open the outlet for the expulsion of the spent material.—H. H.

Cholesterol materials, such as wool-fat; Treatment of crude ——. F. G. Conyers, O. Reynard, and Lanoline Extractors, Ltd. E.P. 179,241, 22.1.21.

The crude material is agitated in direct contact with nitric acid, *e.g.*, of sp. gr. 1·20—1·50, at a temperature of, *e.g.*, 60° to 120° C., until no further reaction occurs and all the water has been expelled, and the product is washed and cooled. The products are neutral, and vary in character from a hard wax-like substance to a highly viscous elastic substance. They may be used for leather-dressing, waterproofing, etc.—H. H.

Soya bean; Process for preparing odourless and colourless oil and flour from ——. Y. Yamamoto and I. Mizusawa. E.P. 179,776, 1.4.21.

The raw bean, coarsely broken and deprived of its bran, it steeped in a weak solution of an organic acid, such as acetic acid, to remove the substances to which the odour and colour are due. The beans bran, is steeped in a weak solution of an organic are then washed free from acid and dried, the oil is extracted, and flour is manufactured from the residue. The acid solution may be warmed slightly, and the washed beans may be treated with a dilue solution of sodium bicarbonate to neutralise any remaining acid. The pulverised bean, after the oil has been extracted, may be warmed with steam to a temperature below the coagulating temperature of the albumin contained in it.—H. C. R.

Edible fatty product from fixed oils and fats and process of manufacturing same. E. Klein. U.S.P. 1,381,564, 14.6.21. Appl., 5.11.18.

Crude cottonseed oil, maize oil, or the like, after treatment with steam and heated air to remove volatile impurities and destroy enzymes, is treated with sodium bisulphite and hydrosulphite together with steam and sterilised air, then treated with alkali, decanted, filtered, and treated with cold sterilised air to separate higher-melting fat and obtain a "winter oil," or until the mass forms an edible fat of solidif. pt. -10° to 15° C. The product should give no blue colour when 10 g. of the melted fat is shaken with 4—5 drops of a 3% solution of hæmoglobin, 10 drops of guaiacum tincture, and 10 c.c. of saturated salt solution.

Fats and oils; Process for separating fatty acids, resins, bitter and mucilaginous substances from ——. H. Bollmann. G.P. 350,698, 31.8.20. Addn. to 345,350 (*cf.* E.P. 164,115; J., 1921, 519 A).

Fat or oil is fed into one side of a vessel provided with division plates and packed with, *e.g.*, Raschig rings, and is treated therein with a counter-current of a purifying liquid, such as a mixture of water with methyl, ethyl, or amyl alcohol, or acetone, or ethyl acetate, which enters the apparatus at the opposite side. One half of the vessel thus contains a high proportion of the solvent, and the other of the fat, while the intimate contact effected between the fat and solvent causes complete removal of impurities without emulsification.—L. A. C.

Catalysts for hydrogenation. G.P. 346,949. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Sublimed white lead; Graphic analysis of ——. B. Paxton. Chem. and Met. Eng., 1922, **26**, 989.

Zinc oxide is determined by boiling 1 g. of the pigment with 6 c.c. of hydrochloric acid, 5 g. of ammonium chloride, and 30 c.c. of water, diluting the solution to 250 c.c. with hot water, adding a little sodium sulphite, and titrating with ferrocyanide, using ammonium molybdate as outside indicator. Lead is determined by boiling 1 g. of the pigment with acid ammonium acetate, diluting the solution to 200 c.c., and titrating with ammonium molybdate. A chart is constructed, by which, from the percentages of zinc oxide and metallic lead, the content of lead sulphate and lead oxide may be ascertained without determining the sulphur trioxide present, assuming that the sum of the zinc oxide, lead oxide, and lead sulphate is 99·7%.—A. R. P.

Resins; Constituents of ——. *VIII. Amyrins from elemi resin. II. α-Amyrin.* A. Zinke, A. Friedrich, O. Johannsen, and R. Richter. Monatsh., 1921, 42, 439—445. (*Cf.* J., 1921, 19 A.)

α-Amyrin benzoate when distilled gives a hydrocarbon, α-amyrene, $C_{30}H_{48}$, which forms a crystalline dibromide, m.p. 259°—260° C. When oxidised with chromic acid, α-amyrin forms a ketone, $C_{30}H_{48}O$, which with benzoyl chloride forms the benzoate of the corresponding enolic compound, α-amyrenol. Bromo-α-amyrin behaves in a similar manner. (*Cf.* J.C.S., 1922, i., 667.)—E. H. R.

Resins; Constituents of ——. *IX. Decomposition of d-siaresinolic acid and lubanyl benzoate.* A. Zinke, F. Hanselmayer, and W. Ehmer. Monatsh., 1921, 42, 447—452.

By oxidation of *d*-siaresinolic acid (*cf.* J., 1919, 187 A) or of its decomposition product, *l*-prabangic acid, $C_{27}H_{40}O_4$, a new crystalline dibasic acid, $C_{21}H_{30}O_5$, was obtained, m.p. 285°—286° C. (decomp.). The formula suggested for lubanyl benzoate by Zinke and Dzrimal (J., 1921, 153 A) has been confirmed by fusion of the benzoate with potassium hydroxide, when protocatechuic acid is formed.—E. H. R.

Patents.

Zinc white [zinc sulphide]; Manufacture of ——. C. Clerc and A. Nihoul. E.P. 157,860, 10.1.21. Conv., 15.11.19.

Precipitated zinc carbonate or zinc oxide obtained from it by treatment with a caustic alkali is suspended in a solution of a zinc salt or of a small proportion of acid, *e.g.*, hydrochloric acid. Hydrogen sulphide is introduced and converts the dissolved zinc salt into zinc sulphide; the liberated acid continuously forms a further quantity of dissolved salt until conversion into sulphide is complete. The product is free from polysulphide and oxysulphide.—D. F. T.

Carbon [black] and similar materials; Process for solidifying ——. C. J. Randall, Assr. to The Goodyear's Metallic Rubber Shoe Co. U.S.P. 1,384,089, 12.7.21. Appl., 30.7.20.

Carbon black or other very finely divided material is placed in a bag of pervious material, the bag is immersed in water in a closed container, air is exhausted from the container, and then gas under pressure is admitted to compact the carbon, thus making it more suitable for transportation and handling.

Carbon [lampblack]; Process for refining crude ——. C. F. C. Herting. U.S.P. 1,416,955, 23.5.22. Appl., 4.10.21.

Crude lampblack is boiled in an alkaline liquid, and the product heated with sulphuric acid until it thickens to a paste, when it is added to a saline solution.—H. R. D.

Plastic materials; Manufacture of ——. W. Petersen and E. V. Clark. E.P. 179,586, 11.1.21.

The initial liquid condensation product of phenol and formaldehyde is mixed with commercial lactic acid of 50—60% concentration, *e.g.*, in the proportions 80:45 by weight, and heated at 100°—110° C. until condensation has proceeded so far that the product no longer adheres firmly to a clean metallic surface. In this condition at 16° C. it forms a very viscous syrup and with filling materials such as

asbestos, wood flour, or china clay, gives mixtures suitable for the production of moulded articles which can be hardened subsequently by baking.
—D. F. T.

Condensation products of benzene derivatives halogenated in the side chain and aromatic hydroxy compounds; Preparation of ——. Kalle und Co. A.-G. G.P. 346,384, 10.5.17.

Oily products, suitable for softening leather and for the preparation of wood stains, or hard resinous products, suitable for use as substitutes for natural acid resins, *e.g.*, in sizing paper, are prepared by treating benzene derivatives halogenated in the side chain with phenols, naphthols, or their derivatives, in the absence of catalysts, until evolution of hydrogen chloride ceases. Benzyl chloride yields oily products with phenol and α- and β-naphthol, while benzyl chloride or xylyl chloride and salicylic acid yield viscous products which harden on standing.—L. A. C.

Coumarone resin and process of making same. L. Rabinovitz, Assr. to Ellis-Foster Co. U.S.P. 1,416,062, 16.5.22. Appl., 12.8.19.

A hard coumarone resin with an iodine value below 50 is made by polymerising the coumarone contained in solvent naphtha by sulphuric acid of 66° B. (sp. gr. 1·84) in the absence of substantial quantities of more dilute acid, agitating the mass thoroughly and then hardening the resin by heating it to about 180° C. in a high vacuum.—A. B. S.

Inks, printing colours, and the like; Manufacture of a binding agent for —— from solutions of glycerin pitch. Chem. Fabr. Plagwitz-Zerbst, G.m.b.H., and J. von Bosse. G.P. 345,141, 30.5.20.

Impurities such as dissolved colloidal substances are precipitated from solutions of glycerin pitch by the addition of salts of heavy metals and/or compounds of the alkaline-earth metals.—L. A. C.

Lime; Production of adherent —— for paints. O. Mielcke. G.P. 346,825, 17.4.20.

Quicklime is slaked by treatment with an alkaline solution, *e.g.*, waste liquor containing alkali hydroxide from the manufacture of soda-cellulose, and after or during the slaking, alum or sodium chloride, and pigments are added.—L. A. C.

Paint; Manufacture of —— for ships' bottoms. E. Arié. G.P. 346,898, 18.2.16.

About 5% of the alkali salts of coconut oil fatty acids, or other saturated monobasic fatty acids of the series C_4 to C_{14}, is added, *e.g.*, to melted colophonium.—L. A. C.

Paint; Water-resistant ——. Manufacture of a binder for coloured carbolineum paint. Plönnis und Co. G.P. (A) 347,707, 11.8.20, and (B) 348,166, 29.5.21. (A) Addn. to 301,783 (J., 1921, 311 A).

(A) The stability and covering power of the paint described in the chief patent are improved by the addition of sulphite-cellulose waste liquor. (B) A mixture of carbolineum with alkalis and water-glass (potassium or sodium silicate, or double water-glass) is employed as a paint, either alone or after the addition of dry colours or other materials.
—L. A. C.

Drying oils, lacquers, varnishes, anti-rust coatings, lubricating oils, etc.; Production of a substitute for ——. W. O. F. Schilsky. G.P. 349,926, 14.7.17. Addn. to 348,087 (J., 1922, 382 A).

Furfural, or a derivative or homologue, is heated under pressure with metal compounds capable of yielding oxygen.—L. A. C.

Lacquers; Manufacture of flexible —— from nitrocellulose. L. Bing and A. Hildesheimer. G.P. 350,973, 17.1.19.

Mono- or diglyceryl esters of non-drying oils, such as the monoglyceryl esters of castor oil or rape oil fatty acids, or the diglyceryl esters of the fatty acids of marine animal oils, are added to solutions of nitrocellulose for use as lacquers.—L. A. C.

Lacquers; Production of flexible —— from cellulose esters. F. Medicus. G.P. 351,228, 14.12.17.

Cinnamic acid esters, *e.g.*, the amyl ester, are added to cellulose esters either before or after solution, yielding flexible, elastic lacquers.—L. A. C.

Resin oils; Preparation of products resembling ——. F. Sichel, Komm.-Ges., and E. Stern. G.P. 351,003, 5.4.21.

Anhydrous zinc chloride is added to resin before or during distillation, or 2—6% of zinc chloride is added to molten resin at a temperature of at least 180° C. The oily products obtained have a saponif. value of 50—40, and are suitable for use in the manufacture of printing colours, lubricating oils, and substitutes for linseed oil.—L. A. C.

Pigment; White ——. H. R. Rafsky. U.S.P. 1,415,391, 9.5.22. Appl., 29.3.16. Renewed 2.6.21.

See E.P. 178,896 of 1921; J., 1922, 474 A.

Sulphurs and vermilions of antimony; Manufacture of gold-coloured ——. P. Chaillaux. U.S.P. 1,417,033, 23.5.22. Appl., 23.6.20.

See E.P. 151,422 of 1919; J., 1920, 756 A.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

[*Rubber;*] *Sodium silicofluoride as a mould preventive* [*for* ——]. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 227—228.

The addition of 0·06% of sodium silicofluoride to standardised latex should be sufficient to inhibit mould growth in the finished smoked sheet rubber. Samples produced in this way were satisfactory, the tensile strength after vulcanisation being good and the rate of vulcanisation slightly less than the average for smoked sheet rubber.—D. F. T.

[*Rubber*] *manufacture; Use of* [*sodium*] *bisulphite in sheet ——.* H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 228—229.

Latex treated with a small quantity of sodium bisulphite yields sheet rubber with an attractive glossy appearance; otherwise bisulphite is unnecessary and indeed the resulting sheet rubber may dry exceptionally slowly. With the addition of 0·1% and 0·2% of sodium bisulphite to latex, the resulting sheets needed smoking for 18 days; the rate of vulcanisation was somewhat reduced, but the tensile strength of the vulcanised product was satisfactory.—D. F. T.

Patents.

Rubber; Treatment of raw ——. S. C. Davidson. E.P. 179,622, 5.2.21.

Rubber coagulum is freed from much of its water by kneading between three rolls. It is then further dehydrated by wrapping the block of rubber tightly, whilst it is still in position between the rolls, in a piece of webbing. This prevents the retraction of the rubber and causes the remaining water to ooze out slowly.—D. F. T.

Rubber substitute, and process for producing same. Western Rubber Co., Assees. of H. H. Hazeltine and M. Gregory. E.P. 157,836, 10.1.21. Conv., 16.3.18.

See U.S.P. 1,360,744 of 1920; J., 1921, 52 A.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome tanning. IX. Relation between the properties of chrome liquors and the leather they produce. D. Burton. J. Soc. Leather Trades Chem., 1922, 6, 157—180.

The effect of the nature of the chrome liquor on the properties of the leather produced is complicated by several factors. The time elapsing between flaying and soaking of the hide should not be prolonged. The preparation of the pelt for the tanning liquor influences the feel of the resulting leather. The initial basicity figure, age, temperature, rate of increase in strength, and the rate of neutralisation of the liquor are important in chrome tanning. The basicity does not always indicate the hydrion concentration of the liquor, which should be controlled. The acidity of the liquor affects the boiling test of the leather and is altered by the presence of neutral salts. The leather is improved by "ageing." It should not be over-neutralised. The feel rather than the absence of shrinkage of the neutralised leather under the boiling test should be used as the criterion of complete tannage. The properties of any sample of leather depend on the condition of the fibre at the moment of fixation by the chromium, the nature of the salt on the fibre and the kind of combination with the pelt, and the mechanical treatment used for softening the leather. There are probably three reactions taking place during chrome tanning, viz., absorption of the liquor by the pelt; chemical combination of the pelt with the free acid; the removal of free acid leads to further hydrolysis, so that the basic chromium salt becomes insoluble in water and is deposited on the fibres. If the chromium compound is negatively charged, due to the adsorption of SO_4 ions which are in excess in the liquor between the fibres, there will be coprecipitation with the positively charged pelt, and chrome tanning will be subject to the same laws as those governing the process of vegetable tanning. A complete bibliography of chrome tanning is appended.—D. W.

Patent.

Hides; Process of deliming ——. W. Savage. U.S.P. 1,382,124, 21.6.21. Appl., 26.4.19.

Depilated hides are subjected to the action of a paste made from an earth capable of adsorbing bases, preferably fuller's earth. Zeolites may be used in place of fuller's earth, but in that case, after removing the paste, the hides must be washed to remove soluble alkali soaps formed by base exchange with the zeolite.

XVI.—SOILS; FERTILISERS.

Soils; Classification of —— on the basis of mechanical analysis. C. L. Whittles. J. Agric. Sci., 1922, 12, 166—181.

A discussion of various methods of classifying soils on the basis of their mechanical composition. The author proposes a graphical method of classification by means of triangular co-ordinates in which the three variables are the fine gravel + coarse sand, the fine sand + silt, and the fine silt + clay. The application of this method to the correlation of mechanical composition and agricultural properties is shown by actual examples. A very full bibliography of the subject of soil classification is appended.—G. W. R.

Sulphates in soil; Factors influencing the determination of ——. C. T. Hirst and J. E. Greaves. Soil Sci., 1922, 13, 231—249.

The chromate volumetric method of estimating sulphates was compared with the gravimetric barium sulphate method, and was shown to be far less inaccurate than is generally supposed. The average recovery of sulphates by the chromate method was found to be 97% of that by the gravimetric method, and where very small quantities were to be estimated the former was found to be the better method. The whole of the sulphate was removed from soil by a 1:5 water extraction after shaking for 40 mins., except where excessive amounts of gypsum were present. The extracts should be cleared by means of a Pasteur-Chamberland filter or by centrifuging. The sulphates were precipitated by excess of a hydrochloric acid solution of barium chromate. The solution was maintained practically at boiling temperature for 30 mins., whereupon the excess of barium chromate was precipitated by the addition of ammonia. After cooling the liquid was made up to standard volume, and allowed to settle and a portion withdrawn for the volumetric determination of the remaining chromate. The presence of nitrates and of salts of iron and aluminium if in considerable quantity tends to produce irregular results.—A. G. P.

Soil; Influence of moisture and soluble salts on the bacterial activities of the ——. J. E. Greaves and E. G. Carter. Soil Sci., 1922, 13, 251—270.

Soil was treated with various salts and the relationships between moisture content and ammonifying and nitrifying powers were determined. The moisture content corresponding to maximum ammonifying power varied with the nature of the salt used. The relative toxicity of sodium chloride, and of the carbonates of sodium, potassium, and calcium decreased as the water content increased. With all other salts used the reverse was the case, indicating that with the latter, other factors than osmotic pressure governed the toxicity. The toxicity of salts towards nitrifying organisms decreased with increasing water content. Optimum moisture content for nitrification was in general a little lower than that for ammonification. (*Cf.* J., 1921, 20 A.)—A. G. P.

Bacteriological activities in soil; Effect of tree products on ——. I. Ammonification and nitrification. W. M. Gibbs and C. H. Werkman. Soil Sci., 1922, 13, 303—322.

Soils were treated with ground sawdust, pine cones and needles, etc., and the effects on ammonification and nitrification studied. All substances examined were injurious to the organisms concerned. The addition of chalk did not destroy the toxicity, although it improved nitrification. Cedar sawdust, followed by maple, larch, ash, and red fir, proved the most inhibitive materials. The miscellaneous débris forming the "forest floor" also reduced formation of ammonia and nitrate in soils. The depression of nitrate accumulation was due to actual toxicity towards the organisms concerned, and was not the result of increased denitrification. —A. G. P.

Nodule formation of soya-beans; Effect of different reactions on the growth and ——. O. C. Bryan. Soil Sci., 1922, 13, 271—302.

Soya-bean plants were grown in sand and solution cultures which were adjusted to various hydrogen

ion concentrations and inoculated with suspensions of nodule bacteria. Shive's solution (Physiol. Res., 1, 327) was suitable for sand but not for solution cultures. Crone's nutrient solution (12 g. of a mixture of KCl 100, $CaSO_4,2H_2O$ 25, $MgSO_4,7H_2O$ 25, $Ca_3(PO_4)_2$ 25, and $FePO_4$ 25 pts. to 8 l. of water) was the more favourable for both sets of experiments. The most favourable reaction for growth and inoculation of soya-beans was p_H 6·5. The limits for inoculation were p_H 4·6—8, and for the growth of the plants p_H 3·9—9·6. Injurious p_H values were within those of very acid soils. Different strains of soya-bean bacteria showed small differences in critical H-ion concentration. The reaction of nutrient solutions in contact with growing plants did not remain constant except when they were initially at the optimum figure. The rate of change of reaction was greater in the alkaline range than in the acid range, and was influenced by the rate of growth of the plant. Maize tolerated greater extremes of reaction than the soya-bean or cowpea, while the last-named showed a greater range of reaction at which nodules formed than the soya-bean. The reaction of plant juices varied with that of the nutrient medium, except the juice of maize leaves, which showed little variation. Root juices followed changes in the nutrient solution reaction more closely than did leaf juices.
—A. G. P.

Phosphates; Citric solubility of mineral ——. J. F. Tocher. J. Agric. Sci., 1922, **12**, 125—143.

The citric solubility of mineral phosphates and slags is dependent on the relative amount of slag or phosphate used, the amount of citric acid used, and the volume of extracting liquid. As a test of the agricultural value of a phosphatic material, citric solubility is unreliable, and the only standard tests to be accepted are total phosphate, fineness of grinding, and freedom from injurious substances. (*Cf.* J.C.S., July.)—G. W. R.

Selenium, sulphur, and tellurium salts; Action of —— *on plants.* B. Turina. Biochem. Zeits., 1922, **129**, 507—533.

The author has examined the action of selenites, selenates, sulphites, sulphates, tellurites, and tellurates on the germination of plants and on the mature plant. From the deposition of selenium and tellurium by reduction in the tissues it is concluded that neither selenium nor tellurium salts enter the system in appreciable quantity, *via* the root hairs, but that the root cap plays the important function of point of entry and of filtration of nutritive salts.—H. K.

XVII.—SUGARS; STARCHES; GUMS.

Nipa-sugar manufacture; Recent improvements in ——. A. H. Wells and G. A. Perkins. Philippine J. Sci., 1922, **20**, 45—56.

The rapid disappearance of crystallisable sugar from the juice or *tuba* of the nipa palm is due in part to enzymes, but without the help of micro-organisms they are not very effective. This fermentation can be largely checked if the tuba is collected in clean receptacles which have been disinfected with lime. This, however, does not retard the conversion of the sugar by inversion into a non-crystallisable mixture of dextrose and lævulose. Preservation of the syrup with toluene was tried on a small scale, and also found to be effective. A very heavy liming of the receptacles with milk of lime containing 600 g. per litre was found very effective in preventing both fermentation and inversion, but was, however, not practicable owing to the accumulation of lime on the receptacles, the formation of calcium saccharate, and other reasons. If only a thin lime cream is used the top layers of tuba become acid and ferment, but this difficulty can be overcome by leading the juice, as it drips from the tree, to the bottom of the receptacle by means of a funnel, and the lime required is thereby reduced to a very small amount.
—G. F. M.

Starch; Determination of the technically recoverable —— *in starch-pulp.* E. Parow. Z. Spiritusind., 1922, **45**, 149.

Estimations of the technically recoverable starch in twelve samples of starch-pulp gave very variable results by the methods usually employed for the purpose, *i.e.*, Klopf's method, the usual washing method, washing with air agitation, total starch by Reinke's method, polarisation, and washing with ammonia. The moisture in six samples each of moist and dry pulp varied from 43·1 to 53·4% and from 13·48 to 15·29% respectively. Polarimetric estimations gave the most consistent results compared with the total starch in the dried samples, as estimated by the Märcker-Delbrück method, except in the case of three dark-coloured samples in which a preliminary decolorisation by treatment with charcoal was necessary before polarimetric readings could be taken. None of the methods gives consistently reliable results.
—L. A. C.

Starch; Dakamballi ——. J. A. Goodson. Analyst, 1922, **47**, 205—206.

This starch is prepared in British Guiana from the fruit of the tree *Aldina insignis*. The powder has a pale brown colour, and consists of granules varying from 11 to 42 μ in diameter. The small granules are mostly circular and the larger roughly ovate in form; the hilum is at the larger end, and the concentric rings are well marked.—W. P. S.

Starch. V. Methyl and acetyl derivatives of the "polyamyloses." H. Pringsheim and W. Persch. Ber., 1922, **55**, 1425—1433.

Octamethyltetra-amylose, in which the third hydroxy group is highly resistant towards methylation, is converted by acetic anhydride and pyridine into octamethyltetra-amylose tetra-acetate, $[\alpha]_D^{20} = +118{\cdot}62^{\circ}$ in ethyl alcohol. Diamylose resembles tetra-amylose in that it is transformed by successive treatment with methyl sulphate and sodium hydroxide and with methyl iodide and silver oxide into tetramethyldiamylose, $[\alpha]_D^{20} = +143{\cdot}74^{\circ}$ in ethyl alcoholic solution. Attempts to methylate the third hydroxy group were unsuccessful. The behaviour of the polyamyloses of the β-series towards methylation is peculiar. With hexa-amylose, reducing action towards Fehling's solution is observed after a single treatment with sodium hydroxide and methyl sulphate. With triamylose the phenomenon is noticeable only after the first treatment with methyl iodide and silver oxide, and becomes more marked after a second treatment with the same reagents. If the "slime" obtained by the degradation of starch with *B. macerans* be treated with pyridine and acetic anhydride, dodeka-α-acetylhexa-amylose, $[\alpha]_D^{20} = +95{\cdot}77°$ in glacial acetic acid solution, is obtained. It is reconverted by alcoholic potassium hydroxide solution into the initial material, which is thus charactertised as α-hexa-amylose. (*Cf.* J.C.S., 1922, i., 632.)—H. W.

Starch. VI. Polyamyloses. H. Pringsheim and D. Dernikos. Ber., 1922, 55, 1433—1445.

α-Tetra-amylose is converted by acetic anhydride and pyridine into α-tetra-amylose dodeka-acetate, $[C_6H_7O_2(OC_2H_3O)_3]_4$, $[\alpha]_D^{18} = +115{\cdot}8°$ in glacial acetic acid solution, which is re-converted by alcoholic potassium hydroxide solution into α-tetra-amylose. Possibly by reason of necessarily more drastic experimental conditions, β-hexa-amylose is depolymerised by acetic anhydride and pyridine and converted into the same triamylose monoacetate as is obtained by acetylation in the presence of zinc chloride. Arguments are brought forward against Karrer's view of the identity of triamylose and β-hexa-amylose (J., 1922, 304 A). (*Cf.* J.C.S., 1922, i., 632.)—H. W.

Starch. VII. Relationship of the α- and β-polysubstance of the starch granule. H. Pringsheim and K. Goldstein. Ber., 1922, 55, 1446—1449.

It has been shown by Samec and his co-workers (J., 1921, 272 A) that starch can be separated by electrodialysis into erythroamyloses and amyloamyloses. The close relationship of these substances to the β- and α-polyamyloses is illustrated by the colorations which they give with iodine and the readiness with which additive compounds are produced with this halogen, by the relative specific rotations, and by the ratio of the molecular weights. In the fermentation of the amylopectins and amyloses by *B. macerans* β-polyamyloses are obtained in larger yield from the erythro-, and α-polyamyloses from the amylo-amyloses. (*Cf.* J.C.S., 1922, i., 633.)—H. W.

Inulin. II. Inulin and glycogen. H. Pringsheim and M. Lassmann. Ber., 1922, 55, 1409—1414.

Re-determinations of the molecular weight of inulin acetate dissolved in glacial acetic acid by the method of Barger (Trans. Chem. Soc., 1904, 85, 286) as modified by Rast (Ber., 1921, 54, 1979) have confirmed previous measurements (*cf.* J., 1921, 523 A), but the process cannot be applied in the cases of the acetates of glycogen or soluble starch. The method does not appear to be practicable for the determination of molecular weights exceeding 3000. Glycogen is transformed by acetic anhydride in the presence of pyridine into its acetate, $C_{12}H_{16}O_8$, m.p. (indefinite) 165° C., $[\alpha]_D^{18} = +159{\cdot}6°$ when dissolved in pyridine. Soluble starch likewise yields an acetate, which differs from that of glycogen, whereas the substances give the same product when methylated (Karrer, J., 1922, 27 A). The possibility that the differing behaviour of glycogen and starch towards iodine is attributable to the presence of impurities (*loc. cit.*) is greatly discounted by the observation that the substances obtained by the de-acetylation of glycogen and starch acetates give the same colorations as the initial materials.—H. W.

Inulin. III. H. Pringsheim and A. Aronowsky. Ber., 1922, 55, 1414—1425.

Attempts to confirm the identity of inulin regenerated from its acetate with natural inulin by fermentative hydrolyses with *Penicillium glaucum* show that the behaviour of the ferment depends greatly on its mode of culture. A specimen nourished with glucose did not hydrolyse inulin, whereas a similar specimen nourished with inulin was active towards the latter only and one nourished with de-acetylated inulin acetate hydrolysed natural and artificial inulins. Inulin (1 pt.) is converted by glacial acetic acid (2 pts.) and acetic anhydride (2 pts.) into an inulin acetate which could not be caused to solidify but was transformed by sodium ethoxide in the presence of absolute alcohol into trifructose-sodium, $(C_6H_{10}O_5)_3$,NaOH. Trifructose could not be isolated in substance, nor could other derivatives of it be prepared. It appears therefore that inulin in the solid condition and in its colloidal solution is the product of a trebly polymerised anhydrotrifructose. Inulin-sodium has the composition $(C_6H_{10}O_5)_3$,NaOH, whether obtained by precipitating a solution of inulin in sodium hydroxide (10%) by alcohol or by the hydrolysis of inulin acetate with sodium ethoxide. It is, however, pointed out that the first method for the preparation of the additive compounds of polysaccharide and sodium hydroxide is unreliable; the sodium content depends entirely on the concentration of the sodium hydroxide solution from which they are precipitated by alcohol, or on the quantity of water with which they are treated for the removal of adherent sodium hydroxide. (*Cf.* J.C.S., 1922, i., 635.)—H. W.

Patent.

Corn [maize] starch; Manufacture of —— and products therefrom. A. W. H. Lenders, Assrs. to Penick and Ford, Ltd. U.S.P. 1,417,467, 23.5.22. Appl., 18.11.18.

See E.P. 149,374 of 1919; J., 1920, 700 A.

XVIII.—FERMENTATION INDUSTRIES.

Saccharomyces Marxianus and top-fermentation yeasts. R. H. von Euler and K. Josephson. Z. physiol. Chem., 1922, 120, 42—60.

Saccharomyces Marxianus failed to ferment maltose even on the addition of an excess of co-enzyme. It also does not ferment this sugar at a higher temperature, namely, 40°C. Its fermenting capacity is diminished on drying and increases again as the cells imbibe. It ferments sucrose and dextrose with the same velocity. The development of the yeast in dextrose and in maltose solutions is of approximately the same order and follows the ordinary exponential law. Its inverting capacity is about 100 times lower than that of culture yeasts. In the case of the top-fermentation yeast R both treatment with alcohol and drying diminish its activity. The inverting capacity of yeast R is greater than that of the top-fermentation yeast S B.—S. S. Z.

Fat; Enzymic synthesis of ——. L. Spiegel. Z. physiol. Chem., 1922, 120, 103—109.

On incubating cellulose, dextrose, and starch with enzyme preparations from certain oil-bearing seeds a small production of fatty substances was observed.
—S. S. Z.

Diastase; Regeneration of —— and its dependence on oxygen. W. Biedermann. Biochem. Zeits., 1922, 129, 582—593.

If active filtered saliva be heated just to 100° C. it becomes turbid. The diastatic activity of the solution is small, but is regenerated to a considerable extent by vigorous shaking with air. If, however, the heated saliva be again filtered the filtrate, free from oxygen, is practically inactive, but is slightly activated by shaking with air. This activation is attributed to oxygen, although the finely divided coagulated protein plays a part.
—H. K.

Oxalic acid and ammonia; Formation of —— in cultures of Aspergillus niger on peptone. W. Butkewitsch. Biochem. Zeits., 1922, **129**, 445—454.

The proportion of ammonia and oxalic acid formed from cultures of *Aspergillus niger* on peptone corresponds to ammonium oxalate with about 10% excess of ammonia. Of the ammonia formed over a period of 40 days 90% appeared in the first 10 days during the vigorous growth of the mould.—H. K.

Peptone as source of carbon for species of Citromyces. W. Butkewitsch. Biochem. Zeits., 1922, **129**, 455-463.

Citromyces glaber and *citricus* grown on peptone media produce ammonia and oxalic acid (not citric acid), the proportion of ammonia being 12 to 20% greater than that required for ammonium oxalate. As in the case of *Aspergillus niger* (*cf. supra*), the major portion of the ammonia is produced in the first period of growth, and the ratio of the yield of mould to ammonia nitrogen falls off with the age of the cultures.—H. K.

Oxalic acid; Formation and accumulation of —— in cultures of Citromyces on salts of organic acids. W. Butkewitsch. Biochem. Zeits., 1922, **129**, 464—476.

Salts of organic acids are utilised by species of *Citromyces* with production of oxalic acid, the sodium salts being more conducive to growth than the ammonium salts. *Aspergillus niger* converts tartaric acid rapidly into oxalic acid; *Citromyces* are unable to do this, but on salts of citric, succinic, and quinic acids there is considerable formation of oxalic acid.—H. K.

Wine; Estimation of the various acids in ——. T. von Fellenberg. Z. Unters. Nahr. Genussm., 1922, **43**, 217—255.

The scheme of analysis described permits of the estimation in wine of the separate proportions of weak organic acids (tannic acids), tartaric, malic, succinic, and lactic acids. The most important feature in the scheme consists in the means adopted to estimate the last four acids. These acids are converted into their silver salts, silver lactate remaining in solution, whilst the other three silver salts are precipitated. The tartaric acid is estimated by the official Swiss method, so that the sum of the malic and succinic acids may be calculated. The aqueous solution containing these two acids is shaken with ether, the proportions of the separate acids being determined from their distribution between the water and ether and the known values of the separate distribution coefficients. Full details of the procedure are given.—T. H. P.

Patents.

Glycerin; Production of —— from sugar. Vereinigte Chem. Werke, A.-G. G.P. 343,321, 14.2.17.

In the production of glycerin from sugar, the fermentation is carried out in the presence of salts with an acid or neutral reaction, *e.g.*, ferrous sulphate, aluminium sulphate, ammonium chloride, or calcium chloride, as well as a considerable excess of nutrient salts such as ammonium sulphate, sodium phosphate, potassium sulphate, and magnesium phosphate. Fermentation is allowed to proceed until the whole of the sugar has been decomposed.—L. A. C.

Alcoholic fermentation; Production of material from pancreas or yeast for accelerating ——. J. D. Riedel, A.-G. G.P. 350,640, 5.11.20.

Pancreas or yeast powder is triturated with *liquor ferri sesquichlorati*, dried below 105° C., washed until no more iron salts dissolve, boiled from ¼ to ½ hr. with a 2% alkali solution, and filtered. The solution may be treated with acids to precipitate metabolin, or may be used direct for the preparation of the products described in G.P. 345,695 (J., 1922, 430 A).—L. A. C.

Products from lupins. G.P. 350,100. *See* XIXA.

XIXA.—FOODS.

Dairy practice; Significance of surface tension for ——. O. Rahn. Kolloid-Zeits., 1922, **30**, 341—346. (*Cf.* J., 1921, 746 A, 866 A; 1922, 114 A.)

The foam which forms when skim milk flows from the cream separator is due to a reduction of the surface tension caused by the accumulation in the surface of an albuminous substance which passes into the walls of the foam cells. On standing the walls of the foam cells contain a solid substance and the drying of such material is similar to the drying of many albuminous substances in the sense that it is irreversible. It is probable that this solid albuminous substance is the main constituent of the skin which forms on the surface of milk that has been heated to 60° C. or above. The formation of whipped cream is explained as follows:—On whipping the cream a network of foam is produced, which is stiffened by the solidified fat so that it does not fall like the foam but retains its form. Whipped cream consists of a solid structure of albumin penetrated by layers of solid fat, which has the same form as the foam. On warming whipped cream above the melting point of the fat the structure collapses but remains somewhat frothy because the solid albumin cannot melt. Butter formation is explained as follows:—Cream contains much of the foam-producing albumin; this surrounds the particles of fat and on churning a large volume of air is entrapped by the cream so that the surface is very much enlarged. The albumin passes into the walls of the foam and takes the fat with it, so that a foam rich in fat stands above a liquid poor in fat (buttermilk). The fat particles lie very close together in the foam walls and are compressed into conglomerates by the surface pressure. This causes the albumin in the walls to solidify, and further churning breaks up the foam and mixes the fat conglomerates with the solid albumin to form lumps of butter.—J. F. S.

Butter; Formation of ——. Pt. II. Effect of temperature on butter formation. O. Rahn. Forsch. Geb. Milchwirtsch. und Molkereiw., 1922, **2**, 76—94. Chem. Zentr., 1922, **93**, II., 1147.

The explanation of the process of butter formation advanced previously (*cf.* J., 1922, 114 A) according to which butter can be produced at any temperature, is fundamentally different from Soxhlet's coagulation theory, which states that the butter fat must solidify before it can cohere into lumps. Tabulated data, collected by the author and Hittcher, are given showing the effect of temperature and duration on the process of butter formation. Butter can be produced as long as the liquid froths, even if the fat is liquid in the cream particles, but under these conditions the agglomerates of liquid fat break again, owing to the agitation, and hence the yield of butter is small. The time necessary for the formation of butter decreases with increasing temperature; between 25° and 30° C. it is only 3·5 mins., at lower temperatures a longer time is required, and at 5° C.

probably no butter is formed. In the case of cream from animals fed on pasturage, the solidified fat particles begin to soften at about 11° C., and the softer they are, the more rapidly can the agglomerates of particles coalesce into lumps. When the animals have been fed on roots, the particles are unable to coalesce below about 15°—17° C. The fat content of buttermilk rises gradually with increasing temperature up to about 14°—16° C., and rapidly above that temperature, and is usually a minimum if the duration of the process of butter formation is 30—45 mins.—L. A. O.

Milk; Effect on the percentage composition of —— of variations in the daily volume and variations in the nature of the diet. W. Taylor and A. D. Husband. J. Agric. Sci., 1922, **12**, 111—124.

The percentage composition of milk is apparently determined by the rate of secretion and not by diet, except in the case of non-protein nitrogen, which is not a product of the mammary gland. The percentages of protein, fat, and ash vary inversely and the percentage of lactose directly as the daily volume. It is suggested that the quantity of lactose elaborated by the mammary gland controls the rate of milk secretion.—G. W. R.

Milk; Relation of fat to total solids not fat in ——. F. Reiss. Milchw. Zentr., 1922, **51**, 121—124.

From the statistical study of a number of data as to the composition of milk, it is concluded that there is no strict proportionality between the content of fat and of solids-not-fat.—G. W. R.

Animal bodies; Chemical composition of ——. J. A. Murray. J. Agric. Sci., 1922, **12**, 103—110.

A statistical examination of the relationships between water and the non-fatty matter of animal bodies. From existing data an empirical formula is derived connecting the percentage of water in the fat-free empty weight and the fat-free empty weight. (The "empty weight" is the "live weight" minus the weight of the contents of the stomach, intestines, and urinary bladder.) The formula is applicable to cattle and pigs, and, with slight modification, to sheep. The ratio of protein to ash is the same in sheep and cattle, but higher in pigs. It is not altered with age, but may be affected by food.—G. W. R.

Monoamino-acids [in proteins]; Detection and estimation of ——. R. Engeland. Z. physiol. Chem., 1922, **120**, 130—140.

The author estimated proline in glutin and elastin by means of his betaine method. The former protein showed a content of 10·9% and the latter of 4·3% of proline. The same method was applied in the case of ascitic fluid. Six and a half litres of ascitic fluid yielded 0·06 g. of the chloroaurate of the betaine of leucine and 0·025 g. of the chloroaurate of the betaine of lysine by this method. —S. S. Z.

Proteins; Colloid chemistry of ——. A. Fodor. Kolloid-Zeits., 1922, **30**, 313—336.

The dehydration of protein gels leads, exactly as with a large number of inorganic gels, to the formation of new and more stable molecular structures which are characterised by a reduced tendency to enter into reactions, whilst peptisation of such structures gives, owing to combination with water, reactive disperse particles. The larger or smaller particles obtained by precipitating proteins are not to be regarded as accidental, but as structures containing different amounts of water and of different reactivity. (*Cf.* J.C.S., July.)—J. F. S.

Foods; Examination of —— for the presence of sulphites. A. C. Chapman. Analyst, 1922, **47**, 204—205.

Foods containing onions or mustard yield appreciable quantities of sulphuric acid when they are distilled with phosphoric acid and the distillate is oxidised with bromine; if, however, hydrogen peroxide is used in place of bromine, the volatile sulphur compounds derived from the onions etc. are not oxidised and any sulphuric acid then found is due to the oxidation of sulphur dioxide derived from sulphites contained in the food.—W. P. S.

Allyl mustard oil [allyl isothiocyanate]; Method of estimating —— in mustard. E. Luce and A. Doucet. J. Pharm. Chim., 1922, **25**, 458—464.

In estimating allyl mustard oil in mustard by Dieterich's method (Pharm. Zeit., 1900, 767) the time of maceration of mustard with water should be reduced to 1 hr., and the time of contact with the ammoniacal silver nitrate should be 6 hrs. in the cold or 1 hr. at 80°—85° C. under a reflux condenser. The time of contact and the temperature of maceration are of importance, as rise in temperature or an extension of the maceration beyond one hour results in a secondary reaction occurring with consequent loss of allyl mustard oil.—W. G.

Patents.

Rice; Parboiling, gelatinising, and similarly treating —— and apparatus therefor. H. Simon, Ltd., C. Raeburn, and A. G. Simpson. E.P. 179,206, 2.11.20.

Soaked rice is heated under atmospheric pressure by contact with, and the radiation of heat from, the walls of externally heated containers through which the rice descends under gravity, and the discharge is controlled, *e.g.*, by a reciprocating grid, to regulate the duration of heating. Air may be passed upwards through the rice to carry off the moisture. A number of such containers of small cross-section may be combined in parallel in one apparatus, and each container may be in the form of a corrugated or indented tube.—H. H.

Milk and cream; Process of extracting butter fat or oil from ——. C. E. North. U.S.P. 1,416,053, 16.5.22. Appl., 4.9.20.

Cream is agitated to agglomerate the fat particles and then mixed with water at such a temperature that the agglomerated particles are liquefied, and in such amount that the fat rises as an oily layer. —H. H.

Nut kernels; Process of treating —— to produce food ingredients. H. R. and L. E. Scott. U.S.P. 1,416,128, 16.5.22. Appl., 1.7.20.

Prune, peach and apricot kernels are subjected to the action of the enzyme emulsin existing therein, in the presence of water, to decompose the amygdalin. The aqueous solution is separated by filtration and distilled to recover benzaldehyde and hydrocyanic acid products, while the meal is washed to remove remaining soluble constituents.—L. A. C.

Fibrous vegetable material, especially wood; Process for decomposing ——, e.g., for the production of fodder. P. Waentig. G.P. 349,842, 19.9.17.

Moist vegetable material cut up into small pieces is treated with chlorine, washed, treated at the ordinary temperature with a dilute alkaline solution free from sulphur, and again washed.—L. A. C.

Fodder; Manufacture of —— from straw. J. Paechtner. G.P. 351,051, 1.10.20. Conv., 4.10.19. Addn. to 338,920 (J., 1921, 714 a).

By-products obtained in the utilisation of agricultural products, such as molasses, vinasse, beet slices, and the like, and which contain electrolytes, are added to finely divided straw previous to electrolysis as described in the chief patent. The straw can also be treated with a direct current in the presence of water without the addition of electrolytes.—L. A. C.

Lupins; Preparation of products containing albumin and free from bitter constituents from ——. C. F. Hildebrandt. G.P. 350,100, 11.12.17.

Lupins are ground with water after removal of the husks, and after separation of the aqueous extract, the residue, which contains the greater part of the albuminous constituents, is washed until free from all bitter substances. The albumins in the aqueous extract are precipitated and separated from the solution, which can then be employed for the production of alcohol and yeast.—L. A. C.

Lupins; Removal of bitter substances from —— *by means of hot water and sodium chloride solution.* P. Bergell. G.P. 350,956, 18.1.21. Addn. to 335,646 (J., 1921, 599 A).

Extraction of bitter substances from lupins by the process described in the chief patent is accelerated and rendered more complete by carrying out the extractions with water at 60° C. under pressure, and with salt solution at 40° C. under reduced pressure.—L. A. C.

Potatoes, onions, tomatoes, apples, or the like; Preparation of dried products from ——. M. Mann. G.P. 350,470, 20.1.20. Addn. to 318,980 (J., 1920, 464 A).

Vegetables and fruits in small pieces are dipped in hot vegetable mucilage, heated to about 100° C. to evaporate the water in the coating, and subsequently dried at progressively lower temperatures.—L. A. C.

Soya bean flour. E.P. 179,776. *See* XII.

Edible fatty product. U.S.P. 1,381,564. *See* XII.

XIXb.—WATER PURIFICATION; SANITATION.

Rock dust in air. Fieldner and others. *See* XXIII.

Patents.

Filters [for boiler-feed water]. J. F. Crawford and W. J. Kelly. E.P. 179,355, 24.2.21.

A gravity filter for boiler-feed water, or for other liquids in large quantity compared with the solid matter, is formed of a series of hollow perforated discs or grids covered with filtering medium and forming a hollow vertical column, down the centre of which the filtrate flows by gravity to a tank at a somewhat lower level than the filtering tank, which is in turn rather lower than a tank in which settling may take place previous to filtration.
—B. M. V.

Fungicide and insecticide. Farbenfabr. vorm. F. Bayer und Co. G.P. 349,870—1, 28.2 and 19.3.15.

A fungicide and insecticide consists of a saturated monocylic ketone, such as cyclohexanone or cyclopentanone or one of their homologues. The substance can be used in the form of vapour, in chemical combination with other substances, such as sodium bisulphite, or in mechanical admixture with soaps, powders, and the like, absorbed in porous substances or dissolved in any suitable solvent.—A. R. P.

Animal membranes; Process for removing poisonous material from ——. H. Braun. G.P. 350,275, 28.8.20.

Animal membranes are treated with a halogen in the presence of a weak acid. The use of *e.g.*, a 5—10% aqueous solution of an acid causes the membrane to swell considerably, and this accelerates the action of the halogen.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine. E. Speyer and G. Becker. Ber., 1922, 55, 1329—1339.

The conversion of morphine oxide by acetic anhydride and sulphuric acid into morphinehydrateoxidesulphonic acid and reduction of the latter by sulphurous acid to morphinehydratesulphonic acid has been described previously. Since, however, the latter substance loses a molecular proportion of water without suffering further decomposition at 170°—180° C. and is catalytically reduced to α-dihydromorphinesulphonic acid it is established that the water is present as solvent of crystallisation and the nomenclature must accordingly be modified to bimolecular morphineoxidesulphonic acid and morphinesulphonic acid respectively. (*Cf.* J.C.S., 1922, i., 675.)—H. W.

Cinchona alkaloids; Action of hydrogen peroxide on ——. E. Speyer and A. G. Becker. Ber., 1922, 55, 1321—1329.

Quinine is converted by hydrogen peroxide (30%) into an amine-oxide which is characterised by its ability to liberate iodine from acidified potassium iodide solution and its re-conversion into quinine by the action of sulphurous acid. Since pyridine and analogous bases do not react with hydrogen peroxide in this manner, the oxygen atom in the oxide is probably attached to the trivalent nitrogen atom of the piperidine complex. Similar oxides are obtained from dihydroquinine, quinidine, dihydrocupreine, and ethyldihydrocupreine, but not from cinchonine. (*Cf.* J.C.S., 1922, i., 674.)
—H. W.

Cinchona series; Syntheses in the ——. *VII. 5.8-Diaminodihydroquinine and 5.8-diamino-6-methoxyquinoline and their conversion into the corresponding aminohydroxy and dihydroxy bases.* W. A. Jacobs and M. Heidelberger. J. Amer. Chem. Soc., 1922, 44, 1073—1079.

Like the amino groups in the aminoazo dyestuffs derived from 5-aminodihydroquinine and 5-amino-6-methoxyquinoline, those in the 5.8-diamino compounds obtained from the dyestuffs by reduction are easily replaceable by hydroxyl groups (*cf.* J., 1921, 96 A). There is evidence that the amino group in position 5 is more labile than that in position 8, and that the substitution of a methoxyl group in position 6 is a determining factor as regards the lability of the amino groups. Certain of the intermediate and end products of this transformation are described. (*Cf.* J.C.S., 1922, i., 671.)—W. G.

Cinchona series; Syntheses in the ——. *VIII. Hydrogenation of dihydrocinchonine, cinchonine, and dihydroquinine.* W. A. Jacobs and M. Heidelberger. J. Amer. Chem. Soc., 1922, 44, 1079—1090.

Dihydrocinchonine, when reduced with sodium in amyl alcohol, yielded a mixture of hexahydrocinchonine and two epimeric hexahydrocinchonanes, in the last of which the alcohol group as well as the quinoline ring had suffered reduction. The relationship of these compounds to the products obtained by reduction with zinc and hydrochloric acid and by the reduction of cinchonine has been elucidated. (*Cf.* J.C.S., 1922, i., 672.)—W. G.

Cinchona series; Syntheses in the ——. IX. Certain quinicine and benzoylcinchona salts, crystalline ethyldihydrocupreine (optochin) base and other derivatives. M. Heidelberger and W. A. Jacobs. J. Amer. Chem. Soc., 1922, **44**, 1091—1098.

A number of miscellaneous crystalline cinchona derivatives are described, many of which were used as initial materials for various researches. (*Cf.* J.C.S., 1922, i., 673.)—W. G.

Cinchona series; Syntheses in the ——. X. Dihydrocinchonicinol and the dihydroquinicinols. M. Heidelberger and W. A. Jacobs. J. Amer. Chem. Soc., 1922, **44**, 1098—1107.

It has been found possible to reduce the ketonic group in cinchona alkaloids of the type of cinchonicine and quinicine by means of palladium and hydrogen, the products being mixtures of stereoisomers of a new type of alkaloids to which the authors have assigned the names dihydrocinchonicinols and dihydroquinicinols. In general the *d*-forms proved easier to isolate, and a number of *d*-bases, one of the *l*-bases, and numerous salts of the *d*- and *l*-forms are described. (*Cf.* J.C.S., 1922, i., 673.)—W. G.

Alkaloids; Methods for the quantitative estimation of ——. P. Herzig. Arch. Pharm., 1922, **259**, 249—308.

The author gives a comprehensive, critical survey of all the known methods—gravimetric, volumetric, colorimetric, refractometric, and polarimetric—for the estimation of alkaloids. Direct weighing has many obvious advantages, but also the great disadvantage that it is difficult without loss to isolate the alkaloid in a sufficiently pure condition. Of all the methods suggested for weighing as insoluble salts or as double salts, only precipitation by picric acid, phospho- or silico-tungstic acid, or picrolonic acid (dinitrophenylmethylpyrazolone) have any practical value. Of these only the last-named is considered to be at all useful, and even here comparative estimations made on *nux vomica* seeds and extracts showed that the results obtained were always 2·5—5% low. Of the volumetric methods, titration with standard acid is the most generally employed. Iodometric estimations are not recommended, but iodometric estimation with iodide-iodate of the excess of acid unneutralised by the alkaloid gives good results except in the case of feeble bases, the sulphates of which are much dissociated, *e.g.*, narcotine, pilocarpine, and purine derivatives, and it is particularly useful if much colouring matter is present. Volumetric precipitation methods using Mayer's reagent, phosphomolybdic acid, potassium ferrocyanide, or picric acid, are regarded as inexact except in special cases such as ferrocyanide for strychnine in presence of brucine, and picric acid for the cinchona alkaloids. Quantitative colorimetric and optical methods all demand the isolation of the alkaloid in a colourless condition, and are in general of little practical value.—G. F. M.

Picrorocellin, a diketopiperazine derivative from Roccella fuciformis; Constitution of ——. M. O. Forster and W. B. Saville. Chem. Soc. Trans., 1922, **121**, 816—827.

By heating at the melting point, or treatment with aqueous sodium hydroxide, picrorocellin, $C_{20}H_{22}O_4N_2$, is converted into anhydropicrorocellin, $C_{20}H_{20}O_3N_2$, while more protracted heating gives xanthorocellin, $C_{19}H_{16}O_2N_2$, by loss of water and methyl alcohol. Methylxanthorocellin, which has been prepared from diketopiperazine, is shown to be 2.5-diketo-3.6-dibenzylidene-1.4-dimethylpiperazine. Xanthorocellin is therefore 2.5-diketo-3.6-dibenzylidene-1-methylpiperazine, which is in accord with the production of benzaldehyde and tetraketo-1-methylpiperazine from it on oxidation with nitric acid. Polarimetric evidence lends further support to the formula

$$\begin{array}{l}C_6H_5.CH(OCH_3).\dot{C}H.N(CH_3).\dot{C}O\\ \qquad\qquad\qquad \dot{C}O-NH-\dot{C}H.CH(OH).C_6H_5\end{array}$$

for picrorocellin, which, however, remains indeterminate regarding the position (1 or 4), of the N-methyl group.—P. V. M.

Melampyritol and aucubin; Presence of —— in the foliated stems of Melampyrum arvense. M. Bridel and M. Braecke. J. Pharm. Chim., 1922, **25**, 449—457. (*Cf.* J., 1921, 674 A.)

The glucoside, aucubin, and the hexahydric alcohol melampyritol (dulcitol) have been isolated from the entire plant of *Melampyrum arvense.* More than 2% of the glucoside was found in a specimen of the plant collected after it had completed its life cycle and when the stem was devoid of leaves.—W. G.

Sensitiveness of cells to poisons as a function of their colloid-chemical condition. H. Handovsky. Kolloid-Zeits., 1922, **30**, 336—341.

The sensitiveness of cells to poisons is closely connected with the stability and variability of the colloid-chemical condition of the protoplasm colloids. The difference of the sensitiveness of red blood corpuscles to poisoning in solutions of sucrose and in solutions of salts is explained as follows:—The sucrose brings about, in the continuously changing sol ⇄ gel system of the protoplasm a more gelatinised condition, which is accompanied by a decrease in the degree of dispersion, and this makes the blood corpuscles less sensitive to surface active poisons. Solutions of salts act in the opposite sense; they make the blood corpuscles in sucrose solution sensitive again, and in those cases where the salt has no hæmolytic action of its own it increases the sensitiveness according to the laws which govern the increase in adsorption brought about by salts.—J. F. S.

Ambergris; Identification of ——. H. I. Cole. Philippine J. Sci., 1922, **20**, 105—109.

A careful microscopical examination often proves of greater value in the identification of substances suspected of being ambergris than the ordinary physical or chemical methods. Genuine ambergris will be found to contain embedded in it thin, dark brown, opaque, finely striated pieces of chitinous material varying from 0·04—0·1 mm. in thickness, derived from the internal shell or gladius of the cuttle fish. Samples of supposed ambergris, resembling in all physical appearances the genuine article, were examined and found to be of vegetable origin. Instead of the horny material above-mentioned, fragments of moss, leaves, and bark were found occluded, and both in this respect and also in m.p. (100°—120° C.) and the character of the ether extract the material closely resembled the latex of *Artocarpus elastica.* True ambergris melts at about 65° C., and the ether extract (ambrein) at 82°—88° C.—G. F. M.

Xanthosterol. H. Dieterle. Arch. Pharm., 1922, 259, 244—245.

The phytosterol, xanthosterol, isolated from the bark of *Xanthoxylon Budrunga* (J., 1920, 81 A) is, apparently, not identical with the lupeol isolated by Goodson (Biochem. J., 1921, 15, 123) from *X. macrophyllum*, for the m. pts. of xanthosterol, its benzoate, and monobromide are below those of lupeol and its corresponding derivatives and mixtures of xanthosterol and lupeol give melting points lower than that of xanthosterol.—G. F. M.

Arsphenamine [salvarsan] solution; Stability of ——. P. Masucci. Amer. J. Pharm., 1922, 94, 338—341.

The oxidation and increase of toxicity of solutions of salvarsan in *N*/1 sodium hydroxide solution (1 mol: 4 mols.) were followed quantitatively by titration with iodine and by injections into white rats. The solutions were prepared in an atmosphere of nitrogen and kept in ampoules filled with that gas. For control purposes solutions of similar concentration in contact with air were also kept. The solutions kept under nitrogen at 0° C. showed no noticeable change of colour, increase in oxidation or toxicity after four months. Solutions kept at ordinary room temperature began to change in colour from yellow to a reddish tinge in about two weeks, and after eight weeks 10% had been oxidised with a marked increase in toxicity. The temperature at which the solutions are kept is therefore a very important factor.—G. F. M.

Neoarsphenamine [neosalvarsan]; Toxicity of ——. M. C. Hart and W. B. Payne. J. Amer. Chem. Soc., 1922, 44, 1150—1160.

The toxicity of commercial samples of neosalvarsan was found to range from 200 to 360 mg. per kg. body weight for rats. In making such tests the variability of the test rats is of importance, as it was found that, in some cases, 40—100 mg. per kg. difference was obtained by the same test made on different rats. An apparatus is described for preparing standard solutions of neosalvarsan and it is suggested that the selection of test rats should be controlled by tests against such a standard. The toxicity of the salvarsan is shown to have only a negligible effect on the toxicity of the neosalvarsan prepared from it. In the condensation of salvarsan to neosalvarsan the influence of solvents, dilution, time and temperature on the toxicity and the introduction of the methylene-sulphinic group and sulphur distribution has been examined. A curve is given showing the lethal activity of a freshly prepared solution of neosalvarsan. The introduction of a methylene-sulphinic acid group in the salvarsan molecule increases the tolerated dose of the material from 110 to 320 mg. per kg. (20% As), but the introduction of the second group was complicated by side reactions giving a higher toxicity.—W. G.

Mercuration in the aromatic series. I. Acetates and hydroxides of mercuryphenol and their derivatives. E. Mameli. Gazz. Chim. Ital., 1922, 52, I., 352—368.

Descriptions are given of the preparation and properties of various ortho- and para-mercuryphenol salts of the form, $HO.C_6H_4.HgX$, where X represents an acid radicle. (*Cf.* J.C.S., July.)
—T. H. P.

Nitroguanidine; Action of sulphuric acid on ——. T. L. Davis. J. Amer. Chem. Soc., 1922, 44, 868—872.

Nitroguanidine is decomposed quantitatively by hot concentrated sulphuric acid, half of the nitrogen being liberated as ammonia and the whole of the carbon as carbon dioxide. Solubility curves are given for nitroguanidine in varying strengths of sulphuric acid at 0° C. and 25° C.—W. G.

Aminoalcohols. Homologues of novocaine. E. Fourneau and J. Puyal. Bull. Soc. Chim., 1922, 31, 424—435.

Hydrocarbons of the ethylene series may be prepared by passing the vapours of the corresponding alcohols over infusorial earth at 400° C. The hydrocarbons may be converted into their bromohydrins by the action of bromine water, and these in turn by the action of dimethyl- or diethylamine give the substituted aminoalcohols, from which certain benzoyl derivatives have been prepared. A commercial sample of amylene, sold under the name of "Pental," was found to contain at the most 20% of β-methyl-Δα-butylene. The hydrochlorides of aminobenzoyldiethylaminopropanol (methylnovocaine) and of aminobenzoyldiethylaminobutanol have a more pronounced anæsthetic action than novocaine. The hydrochloride of *p*-aminobenzoyldimethylaminodimethylethylcarbinol (aminostovaine) has a very intense anæsthetic action. (*Cf.* J.C.S., 1922, i., 639.)—W. G.

Mononitrophenols, mononitrobenzoic acids, and mononitrocinnamic acids; Application of the Kjeldahl method to ——. B. M. Margosches and E. Vogel. Ber., 1922, 55, 1380—1389.

A continuation of previous work (J., 1920, 82 A) in which it was shown that the Kjeldahl-Gunning method gives accurate results only for the ortho derivatives when applied to the mononitrophenols and mononitrobenzoic acids. Decomposition of mononitrophenols and mononitrobenzoic acids by sulphuric acid without addition of potassium sulphate gives correct values for the ortho, low values for the meta and para compounds; the latter are considerably higher than those obtained by the Kjeldahl-Gunning method. Decomposition in stages according to the Kjeldahl-Gunning method shows that in the cases of *o*-nitrophenol and *o*-nitrobenzoic acid the greater part of the nitrogen is converted into ammonia at the period of initial darkening and that the conversion is practically quantitative at the point of most violent action. With *p*-nitrobenzoic acid at the corresponding stages but little conversion has occurred, and during the course of the action the nitrogen gradually undergoes such change that it can no longer be converted into ammonia after addition of phenol. In the case of *p*-nitrobenzoic acid, the replacement of potassium sulphate in the Kjeldahl process by copper oxide or mercuric oxide leads to analytical results which are in harmony with the calculated values. The activity of copper oxide is not affected by the presence of potassium sulphate, whereas that of mercuric oxide is depressed greatly. The activity of sodium sulphate is inferior to that of potassium sulphate and approximately equal to that of lithium sulphate. During the Kjeldahl-Gunning process *p*-nitrobenzoic acid yields a volatile nitrogenous compound, the nitrogen of which can be converted into ammonia by sulphuric acid, phenol, and copper oxide, whereas *p*-nitrophenol undergoes far more complex decomposition with the formation of products which do not yield ammonia under the described conditions. In striking contrast to the nitrobenzoic acids, the three nitrocinnamic acids yield almost the whole of their nitrogen as ammonia when treated with sulphuric acid and potassium sulphate. Satisfactory results are also obtained with sulphuric acid alone or mixed with copper oxide.—H. W.

Alkylbenzylbarbituric acids. A. W. Dox and L. Yoder. J. Amer. Chem. Soc., 1922, 44, 1141—1145.

A series of ethyl alkylbenzylmalonates have been prepared either by alkylating the monobenzylmalonic esters or by benzylating the monoalkylmalonic esters. From these esters the corresponding alkylbenzylbarbituric acids have been obtained by the veronal synthesis with urea and sodium ethoxide. In this series of substituted barbituric acids ethylbenzylbarbituric acid was found to have the strongest physiological action, but, contrary to expectations, the hypnotic effect was accompanied by symptoms of tetanus instead of the antispasmodic effect commonly attributed to the benzyl group. (*Cf.* J.C.S., July.)—W. G.

Acetylsalicylic acid [*aspirin*]; *Commercial* ——. M. V. del Rosario and P. Valenzuela. Philippine J. Sci., 1922, **20**, 15—22.

The methods adopted for the examination of a number of samples of aspirin were titration in alcoholic solution with *N*/5 sodium hydroxide using phenolphthalein as indicator; addition of excess of *N*/5 sodium hydroxide to the neutralised solution, hydrolysis by boiling for 30 minutes, and estimation of the excess of alkali by titration; determination of the bromine value of the hydrolysed solution (1 mol. =3 atoms Br); estimation of free acetic acid by washing 1 g. on a filter with 25 c.c. of cold water and titration of the filtrate; estimation of free salicylic acid colorimetrically with ferric chloride, 0·1 g. of the sample being dissolved in 5 c.c. of alcohol and subsequently diluted to 25 c.c. with water. The authors consider that the requirements of purity should be modified to suit the special climatic conditions of the Philippines, as very few of the samples examined would otherwise conform to them.—G. F. M.

Ammonium carbamate; Transformation of —— [*into urea*]. C. Matignon and M. Fréjacques. Bull. Soc. Chim., 1922, **31**, 394—412.

A résumé of work already published (*cf.* Comptes rend., 1920, **170**, 462; J., 1921, 25 A; 1922, 231 A). —W. G.

Malic acid; Formation of ——. [*Detection of maleic acid in admixture with fumaric and malic acids.*] J. M. Weiss and C. R. Downs. J. Amer. Chem. Soc., 1922, **44**, 1118—1125.

A preliminary study of the equilibrium of maleic, fumaric, and malic acids in aqueous solution over the temperature range, 140°—200° C. At the lower temperature, in aqueous solution, an equilibrium exists among the three acids, but at the higher temperature maleic acid substantially disappears and the equilibrium is between fumaric and malic acids. Further, at the higher temperature approximately the same end-point is reached whether one starts with maleic, fumaric, *i*-malic, or *l*-malic acid. By simple boiling at atmospheric pressure malic acid solutions are practically unchanged. For the detection of small amounts of maleic acid in mixtures with fumaric and malic acids, the solution is saturated with respect to fumaric acid at 25° C., and then the maleic acid is converted into fumaric acid by the addition of a little bromine and the action of the light from a mercury vapour quartz lamp. The solution is again brought to 25° C. and well stirred, and the amount of fumaric acid which separates out is estimated.—W. G.

Acetic anhydride; Analysis of ——. A. Reclaire. Perf. Essent. Oil Rec., 1922, **13**, 148—149.

Ten grams of acetic anhydride is diluted with 75 c.c. of water free from carbon dioxide, heated for 15 mins. under a reflux condenser on a water bath, diluted to 500 c.c. with more water free free from carbon dioxide, and 50 c.c. titrated with *N*/2 potassium hydroxide. The percentage of acetic anhydride present is—

(17·144×c.c. *N*/2 KOH used) - 570·45.

The necessity for using water free from carbon dioxide and potassium hydroxide solution free from carbonate is emphasized. The latter is readily obtained by mixing 1 l. of potassium hydroxide solution with 50 c.c. of milk of lime and allowing to stand for one or more days.—G. F. M.

Ethyl ether; Autoxidation of ——. A. M. Clover. J. Amer. Chem. Soc., 1922, **44**, 1107—1118.

Ether absorbs oxygen from the air slowly at first with the formation of a peroxide by direct addition. The rate of peroxidation becomes much greater in time, however, owing to the catalytic influence of the acetaldehyde, which is formed by the spontaneous decomposition of the peroxide. The peroxide is acidic in character, is volatile, and is slowly decomposed under the influence of light, giving carbon dioxide, methane, acetaldehyde, and alcohol. Hydrogen peroxide is not the primary product of the oxidation of ether, but is formed quantitatively by the decomposition of the peroxide by acidified water. To the peroxide the author assigns the constitution $C_2H_5O.CH(CH_3).O.OH$.—W. G.

Gelatin as a protective colloid. Colloidal silver. A. Gutbier, J. Huber, and A. Zweigle. Kolloid-Zeits., 1922, **30**, 306—316.

Chloroform, toluene, acetone-chloroform, and ethyl acetate are exceedingly good stabilisers for gelatin solutions. The stability of colloidal silver obtained by reduction with hydrazine is increased by the addition of small concentrations of gelatin, but an excess of gelatin has a disturbing effect on the stability of the silver sol. An exceedingly stable and concentrated silver sol was prepared by reducing with hydrazine 10 pts. of *N*/10 silver nitrate in 30 pts. of 0·42% gelatin solution and immediately dialysing for 6 hrs. This sol was red-dish-brown by transmitted light and olive by reflected light; after dialysing for 10 days the preparation contained 40·45% of silver and was stable for three-quarters of a year. Colloidal silver prepared by reduction with sodium hydrosulphite was much less stable than that prepared with hydrazine. The protected silver sols were rapidly coagulated by chlorides (hydrogen, sodium, barium, and magnesium chlorides), *N*/1 sulphuric acid coagulated the sols slowly, but the action was incomplete in 5 days, sodium thiosulphate caused slow sedimentation, whilst sodium hydroxide and sodium carbonate in *N*/1 solutions were without coagulating action.—J. F. S.

Ointments; Examination of B.P. ——. N. Evers and G. D. Elsdon. Analyst, 1922, **47**, 197—201.

Cantharidin ointment. Thirty g. is dissolved in a mixture of equal parts of ether and chloroform, and the solution is extracted three times with 5% sodium carbonate solution; the alkaline solution is acidified with sulphuric acid, extracted three times with chloroform, the extract is evaporated to dryness, the residue washed with a small quantity of a mixture of equal parts of petroleum spirit and absolute alcohol saturated previously with cantharidin, then dissolved in chloroform, the solution filtered through cotton wool, the filtrate evaporated, and the residue dried over sulphuric acid, and weighed. *Calomel ointment.* Five g. of the sample is dissolved in ether, filtered, the insoluble portion washed with ether until free from fat, then dissolved in an excess of standard iodine solution, and the excess of iodine titrated. *Creosote ointment* and *eucalyptus ointment.* The loss in weight when the sample is heated at 100° C. until practically free from odour gives the content of creosote or eucalyptus oil respectively. *Gall ointment.* The amount of powdered galls present is represented by the portion of the sample which is insoluble in petroleum spirit. *Iodine ointment.* The sample is dissolved in chloroform, water is added, and the free iodine is titrated with thiosulphate solution. *Iodoform ointment.* Five g. of the ointment is boiled under a reflux condenser for 2 hrs. with 50 c.c. of *N*/10 silver nitrate solution, the mixture then diluted to 110 c.c., filtered, and

100 c.c. of the filtrate is titrated with thiocyanate solution. The loss in weight when the sample is heated at 100° C. also gives the iodoform content. *Mercury ointment.* Three g. of the sample is heated with 20 c.c. of concentrated nitric acid, the mixture then diluted, and the aqueous liquid separated from the fat; the latter is washed with water, and the united aqueous liquids are oxidised with potassium permanganate solution. Excess of the latter is destroyed by the addition of dilute ferrous sulphate solution and the mercury is then titrated in an aliquot portion of the solution by means of thiocyanate solution. *Compound mercury ointment.* The mercury is determined as described under mercury ointment; the camphor content is determined by heating the sample for 2 hrs. at 100° C. *Resin ointment.* The resin content may be calculated approximately from the formula $(a-5{\cdot}9)\times 100/167$, where a is the acid value of the sample. *Sulphur ointment.* The sulphur is determined by oxidising a portion of the sample with nitric acid and bromine, separating residual fat with ether, and precipitating the sulphuric acid with barium chloride. Except in a few cases, the refractive index does not give much indication as to the amount of active constituent in an ointment.
—W. P. S.

Pollen grain of Pinus silvestris; Constituents of the ——. A. Kiesel. Z. physiol. Chem., 1922, **120**, 85—90.

The ripe pollen contains potassium 0·59%, calcium 0·12%, trace of guanine, adenine 0·002%, little histidine, arginine 0·52%, choline 0·021%, little colamine, and sucrose. The unripe pollen yielded very little in the nuclein bases fraction, traces of histidine, some arginine and choline.—S. S. Z.

Blumea Malcomii; Essential oil from ——. J. L. Simonsen and M. G. Rau. Chem. Soc. Trans., 1922, **121**, 876—883.

The essential oil from *Blumea Malcomii*, from India, has sp. gr. 0·9296 at 30°/30° C., $n_D^{30}=1{\cdot}4749$, $[\alpha]_D^{30}=+46{\cdot}76°$, acid value 0·11, saponification value 22·93, saponification value after acetylation 60·63. It consists mainly of two ketones, *d*-carvotanacetone (Δ^6-menthen-2-one), 82%, and 1-tetrahydrocarvone (*p*-menthen-2-one), 16%, which are readily separated by means of normal sodium sulphite with which the former ketone alone reacts. The sparingly soluble semicarbazone of 1-tetrahydrocarvone is suitable for the separation of this compound from the residual liquors. A trace of yellow oil boiling between 160° and 180° C. at 100 mm. remains after removal of the ketones. The oil contains small quantities of butyric or isobutyric and *n*-octoic acids, and about 0·1% of a phenol.
—P. V. M.

Agastache pallidiflora; Oil of ——. J. F. Couch. Amer. J. Pharm., 1922, **94**, 341—343.

The flowers of the giant hyssop, *Agastache pallidiflora*, contain 0·2—0·3% of a volatile oil having an odour recalling a mixture of thyme and peppermint, whilst the leaves contain a lesser amount of the same or a similar oil, which has an odour of thyme only. The oil isolated by steam distillation of the flowers had the following characters:—Sp. gr. at 20° = 0·91924, $[\alpha]_D^{25}=-8{\cdot}60°$, $n_D^{25}=1{\cdot}4865$. On cooling to −10° C. no crystals separated, hence the amount of free menthol, if present, cannot be very large. Phenols, pulegone and other ketones were not present in the oil.—G. F. M.

Ultra-violet light in analysis. Kitching. *See* XXIII.

Patents.

α-Dialkylaminoethyl-β-aracyl-[hydr]oxybutyric acid esters; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 161,539, 9.4.21. Conv., 10.4.20.

Dialkylaminoethyl halides are caused to react with sodio-ethyl acetoacetate, and the resulting ketonic acid esters are reduced, *e.g.*, by means of sodium amalgam, to α-dialkylaminoethyl-β-hydroxybutyric acid esters of the general formula,

$$CH_3.CH(OH).CH(COOR').CH_2.CH_2.NR_2,$$

where R is an alkyl group and R′ an alkyl or aryl group. Ethyl α-diethylaminoethyl-β-hydroxybutyrate obtained in this way, is a colourless liquid, b.p. 135°—136° C. at 10 mm., soluble in water to an alkaline solution. When this ester is treated with an aromatic acid chloride, *e.g.*, benzoyl chloride, the desired ethyl α-diethylaminoethyl-β-benzoxybutyrate is produced. It is a nearly colourless oil forming a crystalline hydrochloride, m.p. 130°—131° C., readily soluble in water, and possessing valuable local anæsthetic properties.—G. F. M.

Photochemical apparatus. W. O. Snelling. U.S.P. 1,382,252, 21.6.21. Appl., 6.3.17.

A transparent dome rests upon a shallow tray which is provided with an inlet and outlet for gases, one of such conduits being provided with a tube of larger diameter surrounding and extending beyond it. The apparatus is suitable for the chlorination of methane, which together with chlorine enters the dome at one side, the other side of the dome being exposed to an external light source. The reaction products leave the dome at the side nearer the light source, and hence the light has to traverse partially combined gases before meeting the entering gases, whereby the actinic rays are partially absorbed, thus diminishing the reaction velocity and avoiding danger of explosions.—B. M. V.

[Allyl] ether of ethenylparadi[hydr]oxydiphenylamidine; Unsaturated ——. J. Schuler, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,384,637, 12.7.21. Appl., 9.3.21.

Ethenyl-*p*-diallyloxydiphenylamidine, m.p. 85°—86° C., readily soluble in alcohol and ether, insoluble in water, and of value as a local anæsthetic, especially for ophthalmological practice, is obtained by condensing *p*-aminophenyl allyl ether with acet-p-aminophenyl allyl ether in presence of phosphorus halides, phosphorus oxyhalides, or phosphorus pentoxide, and if desired with addition of a solvent or diluent. The hydrochloride of the new ether melts at 152°—153° C., is readily soluble in alcohol, less soluble in water, and insoluble in ether.

Hexamethylenetetramine; Chlorine derivatives of ——. R. Buratti. U.S.P. 1,416,606, 16.5.22. Appl., 18.6.18.

A solution of hexamethylenetetramine is added to a solution of a hypochlorite of a metal classified in the first two metal groups, which has previously been neutralised by the addition of an acid.
—L. A. C.

Hexamethylenetetramine; Preparation of derivatives of ——. *Preparation of addition products of hexamethylenetetramine with monohalogen-fatty acid esters.* J. D. Riedel, A.-G. G.P. (A) 346,383, 14.8.19, and (B) 346,462, 22.7.19.

(A) Non-hygroscopic compounds of therapeutic value and resembling choline are prepared by the action of ethylenehalogenhydrins on hexamethylenetetramine at temperatures above normal in the presence or absence of solvents. The addition products of hexamethylenetetramine with ethylenechlorohydrin and ethyleneiodohydrin have m.p. 135° C. and 149° C. respectively; the product from the latter contains 40·7% of iodine, and is prepared by reaction between the constituents in aqueous solution, or by the addition of sodium iodide to a concentrated aqueous solution of the corresponding chlorine compound. (B) Addition products are formed by reaction between hexamethylenetetramine and esters of monobromoacetic acid with alcohols or phenols which are insoluble or only slightly soluble in water, *e.g.*, borneol and thymol. Aqueous solutions of the compounds hydrolyse slowly on heating, and thus on injection into the body liberate the phenol and the addition product of hexamethylenetetramine with monobromoacetic acid, which has valuable antiseptic properties.—L. A. C.

Benzyl alcohol; Process of producing ——. R. E. Montonna, Assr. to Semet-Solvay Co. U.S.P. 1,416,859, 23.5.22. Appl., 18.5.21.

Benzyl alcohol free from chlorine is prepared by combining crude benzyl alcohol with calcium chloride and subsequently decomposing the compound and separating benzyl alcohol from the residue.—L. A. C.

Nitrophenols; Mercury nitrate as a reagent for the preparation of ——. *Process for the preparation of guanidine.* T. L. Davis. U.S.P. (A) 1,417,368 and (B) 1,417,369, 23.5.22. Appl., 16.4.21.

(A) An aromatic compound is treated with nitric acid and mercury nitrate to produce a complex compound, which is subsequently decomposed to nitrophenol by treatment with nitric acid. (B) Ammonia is used as a hydrolytic agent in the preparation of guanidine from dicyanodiamide. —L. A. C.

Urea; Production of —— *from* [*calcium*] *cyanamide.* Farbw. vorm. Meister, Lucius, und Brüning. G.P. 301,278, 17.3.16.

Iron oxide sludge containing about 83% Fe_3O_4, obtained in the reduction of organic nitro compounds by iron, is added to solutions of calcium cyanamide in, *e.g.*, sulphuric acid, at about 80° C. Conversion to urea is complete after agitation for about an hour. The use of ferrosoferric oxide as catalyst prevents formation of dicyanodiamide, and a smaller quantity of the catalyst is required than if ferric oxide or hydroxide is employed. —L. A. C.

Diethylbarbituric acid and its homologues; Preparation of water-soluble compounds of ——. J. A. Wülfing. G.P. 345,361, 10.10.20.

Solutions of diethylbarbituric acid or its homologues, *e.g.*, phenylethylbarbituric acid, are heated with the calculated quantity of calcium hydroxide, magnesium hydroxide, or freshly precipitated magnesium carbonate. The solutions obtained are filtered and evaporated to dryness *in vacuo*. The products are of therapeutic value, and yield stable mixtures with the alkaline-earth salts of acetylsalicylic acid.—L. A. C.

Fatty acid esters; Preparation of enolic alkali metal compounds of simple ——. W. Scheibler. G.P. 346,698, 16.12.19.

A simple fatty acid ester is added to an alkali metal covered with an inactive solvent, such as ether, benzene, or the like, at a temperature such that the reaction product does not form condensation products, but the hydrogen liberated by the reaction escapes immediately.—L. A. C.

Aminoacetic acid arylides; Preparation of ——. Chem. Fabr. auf Aktien (vorm. E. Schering), and H. Emde. G.P. 346,809, 1.11.19.

Aminoacetic acid arylides, *e.g.*, aminoacetanilide, N-aminoacetyl-*p*-phenetidine, and N-aminoacetyl-*p*-toluidine, m.p. 94° C., are prepared by treating the corresponding isonitrosoacetarylides, Ar.NH.CO.CH:N.OH, with a reducing agent, such as stannous chloride and acetic acid, in the presence of a stream of dry hydrogen chloride, or with tin and dilute acetic or formic acid.—L. A. C.

Sulphonamides; Preparation of mono-substituted ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 346,810, 17.2.20.

Compounds of the general formula, $R'.SO_2.NH.R''$, are prepared without simultaneous formation of di-substituted products by treating sulphonamides with alkylating agents and arylating agents in the presence of metal carbonates. The N-ethylamide and N-benzylamide (m.p. 115°—117° C.) of *p*-toluenesulphonic acid are prepared respectively from *p*-toluenesulphonamide by heating with sodium carbonate and sodium ethylsulphate to 170°—200° C., and by gently boiling with sodium or calcium carbonate and benzyl chloride.—L. A. C.

Cinchona alkaloids; Preparation of mixed carbonic acid esters of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 346,889, 6.2.20.

Quinine alkaloids are either added to acetoneglycerolchlorocarbonic acid esters, or acetoneglycerol is added to chlorocarbonic acid esters of quinine alkaloids, yielding tasteless compounds which are readily hydrolysed and are nearly equal in value to quinine as febrifuges. A solution of carbonyl chloride in benzene on addition to a solution of acetoneglycerol in dimethylaniline yields acetoneglycerolchlorocarbonic ester, an oil of b.p. 95°—97° C. at 8 mm., which on treatment with a solution of quinine in carbon tetrachloride yields acetoneglycerolquininecarbonic acid ester, m.p. 125°—126° C. Solutions of the ester in dilute acid hydrolyse completely into quinine, acetone, and glycerol. The corresponding ester from cinchonine is an oil.—L. A. C.

Citric acid, tartaric acid, and other organic acids which form calcium salts soluble with difficulty in water; Preparation of ——. F. Mach and P. Lederle. G.P. 346,946, 9.1.20.

Aqueous solutions containing the theoretical weight of oxalic acid are added to cold suspensions of calcium citrate, tartrate, or the like, the mixture is stirred and calcium oxalate is separated by filtration. Pure citric or tartaric acid crystallises out after evaporation of the solution, preferably *in vacuo*. Slight excess of oxalic acid or calcium hydroxide in the solution may be neutralised by the addition of calcium hydroxide or oxalic acid respectively. The ammoniacal residues from the estimation of phosphoric acid by the citric acid method are treated with magnesium sulphate or chloride to precipitate phosphoric acid, and with hydrogen sulphide to precipitate iron; hydrochloric acid is added to the solution, and calcium citrate is precipitated by the addition of concentrated calcium chloride solution. The precipitate is converted into citric acid by treatment as above. —L. A. C.

Santonin; Preparation of —— *from indigenous species of Artemisia.* Soteria G.m.b.H., Chem. pharmazeutische Fabr. G.P. 346,947, 21.9.20.

In extracting santonin from *Artemisia maritima* the whole plant is finely divided, ground for a prolonged period with milk-of-lime, and calcium santoninate is extracted with water or dilute alcohol. The solution is evaporated to dryness, and the residue is acidified and extracted with chloroform; after removing resinous compounds by agitation with dilute ammonia, a syrupy residue of santonin is obtained by evaporating the chloroform. —L. A. C.

α-Ketotetrahydronaphthalene; Preparation of ——. G. Schroeter. G.P. 346,948, 21.1.20.

A solution of chromium trioxide in dilute acetic acid is added to a cooled solution of tetrahydronaphthalene in acetic acid. When the solution, which is at first brown, has changed to a clear green, the acetic acid is separated by distillation, and α-ketotetrahydronaphthalene (α-tetralone) is separated from the residue by distillation in a current of steam. The product, $C_6H_4\left\langle\begin{array}{l}CH_2\cdot CH_2\\ CO\cdot CH_2\end{array}\right.$ is a colourless liquid with an aromatic odour, sp. gr. at 17° C. 1·095, $n_D^{17}=1·570$, b.p. 257° C. at 760 mm. and 132°—134° C. at 15 mm.; it condenses with aldehydes in the presence of alkalis yielding alkylidene-tetralones, *e.g.*, benzylidene-tetralone of m.p. 105° C.; and on reduction with sodium and aqueous or absolute alcohol yields *al*-α-tetrahydronaphthol, b.p. 83°—85° C. *in vacuo*, which decomposes on distillation under normal or slightly reduced pressure into water and Δ′-dihydronaphthalene. α-Tetralone can be used for the preparation of drugs and perfumes, and mixed with tetrahydronaphthalene as a solvent for lacquers.

—L. A. C.

Sulphinides; Preparation of metal [gold] compounds of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 347,139, 20.5.19, and (B) 348,070, 24.6.19.

Alkali metal compounds of benzoic acid sulphinides or their derivatives are treated with (A) gold hydroxide or (B) gold halides, yielding products of therapeutic value. An aqueous solution of sodium benzoic acid sulphinide is heated to 100° C. with moist gold hydroxide in the absence of light until nearly the whole of the gold hydroxide has dissolved, and the solution is evaporated *in vacuo* in the absence of light at 40° C. Unchanged benzoic acid sulphinide is separated from the residue by solution in warm acetic acid; on cooling the benzoic acid sulphinide crystallises out, and after separating the crystals, gold benzoic acid sulphinide is precipitated by the addition of ether. The product contains 26·91% Au. Gold sulphoaminobenzoic acid sulphinide, $(NH_2SO_2\cdot C_6H_4<{}^{CO}_{SO_2}>N)_3Au$, contains 20·5% Au.

—L. A. C.

Substances containing a low percentage of hydrogen; Production of organic compounds from ——. [*Catalysts for use in reducing and hydrogenating organic compounds.*] C. Paal and C. Amberger. G.P. 346,949, 10.10.19.

Organic compounds are hydrogenated in the presence of a catalyst consisting of an organosol of platinum or palladium, or their hydroxides, with wool fat or its constituents, *i.e.*, cholesterol or isocholesterol, or their derivatives. Compounds which are insoluble in water or in mixtures of water and organic solvents can be reduced in the presence of these catalysts. Reduction can be effected in the presence of all solvents in which wool fat is soluble, and is promoted by the presence of water or mixtures of water and organic solvents. Organic solvents not miscible with water or aqueous solvents, such as aliphatic or aromatic hydrocarbons, ether, solid and liquid fats, olefinic and true terpenes, or their derivatives, may also be employed, but liquids with an anti-catalytic action, such as sulphur compounds, are unsuitable for use as solvents. Reduction readily takes place at room temperature and under normal or reduced pressure, and is accelerated by increased temperature or pressure. Ethylene and acetylene groups, Schiff's bases, hydrazones, osazones, nitriles, azoxy-, azo-, nitroso-, and nitro groups are capable of direct reduction by hydrogen in the presence of these catalysts. Examples are given of the hydrogenation of oils such as castor oil, linseed oil, and cottonseed oil; the hydrogenation of geraniol in stages to citronellol (dihydrogeraniol) and to tetrahydrogeraniol; the preparation of the dihydroderivatives of cinchona alkaloids, such as quinine, cinchonine, and quinidine, by treating the alkaloids dissolved in freshly distilled amyl acetate with hydrogen at 50°—60° C. under an excess pressure of 2—4 atm. in the presence of platinum or palladium hydroxide wool fat organosols; of the conversion of morphine, diacetylmorphine, and codeine in solution in freshly distilled amyl acetate and acetic acid, or of phenetol, to their dihydro derivatives; and of the reduction of benzylideneaniline to benzylaniline, benzylidenephenylhydrazine to benzylphenylhydrazine, and *m*-dinitrobenzene to *m*-nitraniline and *m*-phenylenediamine, with the use of amyl acetate or ethyl caprate as solvent.—L. A. C.

Acetic acid; Recovery of chemically pure —— *from acetic acid containing mercury, e.g., synthetic acetic acid prepared with mercury as catalyst.* Chem. Fabr. Griesheim-Elektron, and N. Grünstein. G. P. 347,190, 17.4.15.

Acetic acid containing small quantities of mercury is heated with material capable of reacting with the mercury, *e.g.*, reducing or oxidising agents, strong acids, salts, etc. The acetic acid may be boiled for a prolonged period with small quantities of organic material, such as cork or rubber, and purified by distillation, after separation of the mercury deposited. Separation of the mercury is more rapid if the acid is heated with concentrated sulphuric or phosphoric acid, or alkali, heavy metal, or aluminium sulphates, or with permanganates, bichromates, or persulphates, or reducing agents such as formic acid. If strong oxidising agents are employed, such as mixtures of sulphuric acid with bichromates, chromates, or permanganates, the acetic acid is purified by removal of impurities such as acetaldehyde, and the mercury is partially converted into salts, which are separated from the acetic acid by distillation *in vacuo*.—L. A. C.

3-*Nitroquinoline and its derivatives; Preparation of* ——. Badische Anilin- und Soda-Fabr. G.P. 347,375, 8.2.20. Addn. to 335,197 (J., 1921, 463 A).

β-Nitroethylidenearylamino-*o*-carboxylic acids, or their derivatives, prepared by treating *o*-aminoarylcarboxylic acids, or their derivatives, with methazonic acid, are treated with condensing agents. 2-β-Nitroethylideneaminobenzene-1-carboxylic acid, m.p. 196°—197° C., 2-β-nitroethylideneamino-5-bromobenzene-1-carboxylic acid, m.p. 182° C. (decomp.), and 2-β-nitroethylideneaminonaphthalene-3-carboxylic acid, prepared by the action of methazonic acid on anthranilic acid, 5-bromo-2-aminobenzene-3-carboxylic acid, and 2-aminonaphthalene-3-carboxylic acid respectively, on heating with acetic anhydride and anhydrous sodium acetate yield respectively 3-nitro-4-hydroxyquinoline, m.p. above 300° C., 3-nitro-4-hydroxy-6-bromoquinoline, m.p. above 300° C., and 3-nitro-4-hydroxy-α-anthrapyridine, m.p. above 300° C.

—L. A. C.

Gold compounds of the Methylene Blue group; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 347,376, 20.5.19.

Compounds of the Methylene Blue group, such as Methylene Blue, dimethyldiethyl-, or tetraethyldiaminophenazthionium, combine in alcoholic solution with gold compounds, *e.g.*, gold chloride

or nitrate, yielding compounds with a strong antiseptic action against *Bacillus pyocyaneus* and *Gonococci*, *Spirochaete*, and tubercle bacilli.
—L. A. C.

Amino-alcohols; Preparation of ——. P. Karrer. G.P. 347,377, 24.8.20.

AMINO-ALCOHOLS are prepared by the reduction of N-acyl derivatives of aminocarboxylic acid esters, or mixtures of the same, with sodium and ethyl alcohol. A mixture of acetylleucine with absolute ethyl alcohol is added slowly to sodium, the mixture is heated gently, and finally boiled for 3 hrs. The solution is diluted with water, alcohol is separated by distillation with simultaneous hydrolysis of the acetyl group, and 1-isobutylethyl-1-aminoalcohol-2, $(CH_3)_2.CH.CH_2.CH(NH_2).CH_2OH$, is extracted by shaking with ether, the solvent being subsequently removed by distillation, yielding a colourless, strongly basic oil of b.p. 194°—200° C. Optically active leucine (natural leucine) yields lævorotatory isobutylethylamino-alcohol. Acetylphenylalanine ethyl ester yields 1-benzyl-1-aminoethyl-alcohol-2, b.p., *in vacuo*, 150°—160° C. The mixture of acetylaminocarboxylic acid esters obtained from casein by hydrolysis and subsequent esterification and acetylation yields a mixture of products which can be separated by distillation *in vacuo* into fractions as follows: b.p. up to 175° C. containing colamine and alaninol; b.p. 105°—190° C. at 16 mm., containing valine alcohol, leucine alcohol, and phenylalanine alcohol; b.p. 190°—235° C. at 16 mm. The products are of therapeutic value.—L. A. C.

Ointments; Preparation of —— which leave no greasy appearance on the skin. Erdöl- und Kohle-Verwertung A.-G., and F. Zernik. G.P. 347,399, 12.4.19.

COLLOIDAL hydrogels of inorganic bases containing a high percentage of water, *e.g.*, colloidal aluminium hydroxide containing 90% of water, are mixed with oils or fats, *e.g.*, vaseline. The products serve as cooling ointments.—L. A. C.

Chloroform; Production of —— from acetaldehyde. Consortium für Elektrochem. Ind., G.m.b.H. G.P. 347,460, 3.3.14. Addn. to 339,914 (J., 1921, 828 A).

IN the process described in the chief patent alkaline-earth hypochlorites are preferably employed, and the mixture is heated during the reaction. A 20% aqueous solution of acetaldehyde is added gradually to a stirred solution of calcium hypochlorite at 45° C. containing 93 g. of active chlorine per l., and after stirring for a short time at the same temperature, and subsequently neutralising the calcium hydroxide with hydrochloric acid, chloroform is separated by distillation. A yield of 80% of chloroform is claimed.—L. A. C.

Kola extract; Preparation of a ——. A. Stephan. G.P. 347,482, 2.8.19.

COARSELY-GROUND, well washed kola nuts, free from dust, are covered with water and treated with carbon dioxide under slight pressure. The mixture is allowed to stand for eight days with occasional shaking, and is then filtered and either concentrated by evaporation or added to mineral waters or pharmaceutical preparations. The presence of carbon dioxide during the extraction inhibits the formation of mould.—L. A. C.

Arylides of aromatic hydroxycarboxylic acids; Preparation of ——. Chem. Fabr. Griesheim-Elektron. G.P. 347,607, 6.9.17.

AROMATIC hydroxycarboxylic acids on treatment with the aluminium or magnesium compounds of aromatic amines react as follows: $R^1.CO_2H+R.NH.M=R^1.CO.NH.R+M(OH)_2$ (R^1=hydroxyaryl, R=aryl, M=metal). Examples are given of the preparation of 2.3- and 1.2-hydroxynaphthoic acid anilides, m.p. of the 1.2-derivative, 145° C. (154° C. on recrystallisation from ether), and salicylic acid anilide, m.p 134° C.—L. A. C.

Bromodialkylacetylureas; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 347,609, 27.11.15.

DIALKYLMALONURIC acids of the general formula, $X_2C(COOH).CO.NH.CO.NH_2$(X=alkyl), are treated with bromine at 100° C., in the presence or absence of solvents, diluents, or bromine-carriers, such as aluminium chloride, until evolution of hydrogen bromide and carbon dioxide ceases. After removal of excess bromine, the products are stirred with water, neutralised with sodium bicarbonate, washed, and recrystallised from dilute alcohol. Diethylbromoacetylurea has m.p. 118°—120° C.
—L. A. C.

β-Nitropropenyl compounds; Preparation of ——. Preparation of ethers of aromatic nitro-alcohols. (A) E. Schmidt and A. Wagner, (B) E. Schmidt and W. Bäjen. G.P. (A) 347,818, 26.2.20, and (B) 348,382, 12.3.20.

(A) AROMATIC propenyl compounds are treated with tetranitromethane or hexanitroethane in the presence of compounds with an alkaline reaction, *e.g.*, tetranitromethane is added, drop by drop, to an ice-cooled solution of isosafrol in acetone and pyridine. When the smell of tetranitromethane has disappeared the solution is shaken with water and extracted with ether. The ether extract is washed successively with potassium hydroxide and dilute acid, dried over anhydrous sodium sulphate, and the ether is separated by distillation, yielding β-nitroisosafrol, $CH_2:O_2:C_6H_3.CH:C(NO_2).CH_3$, m.p. 98° C. The corresponding nitro compounds of anethol, isoeugenol, asaron, and isoapiol are obtained by a similar method. The compounds readily split off the elements of water, yielding nitro-alcohols which on reduction form amino-alcohols of therapeutic value. (B) If the reaction described in (A) is carried out in the presence of an alcohol instead of a compound with an alkaline reaction, such as pyridine, the unsaturated compounds formed thereby simultaneously form addition products with the alcohol, yielding ethers of nitro-alcohols. Thus, anethod on treatment with tetranitromethane in the presence of methyl or ethyl alcohol yields respectively the methyl ether or ethyl ether of 3-*p*-methoxyphenyl-2-nitropropanol. The methyl ether has m.p. 50°—51° C. Similar ethers can be prepared fro *o*-propenylanisol and isosafrol.—L. A. C.

Urea melts from carbonic acid compounds of ammonia; Treatment of ——. Badische Anilin- und Soda-Fabr. G.P. 350,051, 31.8.20.

UNDECOMPOSED ammonium salts present in urea melts are removed by heating the melts under pressure for a short time to such a temperature, *e.g.*, 200° C., that practically the whole of the ammonium salts are volatilised, after, if desired, removal of a portion of the salts by heating to a lower temperature, *e.g.*, 120° C., under pressure.—L. A. C.

Alcohol; Manufacture of ——. Badische Anilin- und Soda-Fabr. E.P. 158,906, 9.2.21. Conv., 9.2.20.

SEE U.S.P. 1,410,223 of 1922; J., 1922, 347 A.

Aralkyl ester of 2-phenylquinoline-4-carboxylic acid. A. Gams and O. Kaiser, Assrs. to Soc. of Chem. Ind. in Basle. U.S.P. 1,378,343, 17.5.21. Appl., 23.6.20.

SEE E.P. 167,066 of 1920; J., 1921, 717 A.

Silver Salts of α-amino-acids; Complex ——. M. Guggenheim, Assr. to The Hoffmann-La Roche Chemical Works. U.S.P. 1,417,167, 23.5.22. Appl., 30.9.19.

See G.P. 339,036 of 1919; J., 1921, 717 A.

Urea; Process of producing —— from lime nitrogen [calcium cyanamide]. O. Nydegger and H. Schellenberg. U.S.P. 1,417,277, 23.5.22. Appl., 6.11.20.

See E.P. 153,574 of 1920; J., 1922, 157 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

2-p-Dimethylaminostyrylpyridine methiodide, a new photographic sensitiser. W. H. Mills and W. J. Pope. Chem. Soc. Trans., 1922, **121**, 946—947.

By the condensation by boiling of *p*-dimethylaminobenzaldehyde with α-picoline methiodide and piperidine in alcohol, 2-*p*-dimethylaminostyrylpyridine methiodide, $C_{16}H_{19}N_2I$, bright red prisms with a blue reflex, m.p. 275° C., is produced. Aqueous solutions dye silk a bright orange-yellow, not fast to light. Such solutions are decolorised, but to a less extent than are the isocyanines, by mineral acids. Alcoholic solutions show absorption bands in the blue and green with obscurely marked maxima at about λ4750 and λ4600. The new substance is the most powerful sensitiser for green light yet known for gelatin-silver bromide photographic plates, which, after bathing in aqueous solutions containing 1 pt. of the dyestuff in 30,000 or 40,000 pts. of solution, show almost uniform sensitiveness to light of all wave-lengths from the blue to about λ5600; the photo-sensitiveness then falls off rapidly until it ends at about λ6200. A number of sensitising dyestuffs of this type may be prepared by replacing the α-picoline by its derivatives.—P. V. M.

Capillary attraction, diffusion and displacement [; Application of —— to washing photographic plates, etc.]. L. Lumière. Bull. Soc. Franç. Phot., 1922, **9**, 125—130.

When a band of fabric is suspended vertically so that its upper end dips into water or other liquid capable of wetting it, a slow stream passes down the band, which acts as a kind of capillary siphon. The rate of flow depends on the nature of the material and, up to a certain point, on the difference in level between the upper and lower ends of the band; after a certain value, any increase in this difference produces no difference in the rate of flow. This phenomenon is applied in an apparatus for washing photographic plates. In this the plates are gently pressed against a band of cotton fabric carrying a stream of water in the manner described. Further applications given are the washing of precipitates when only very small quantities of wash water may be allowed, and the extraction of soluble contents of powdered materials.—W. C.

Patents.

Photographic films with a carrier permeable to water. J. E. Brandenberger. E.P. 179,250, 26.1.21.

In order to produce a layer of photo-sensitive material on one surface only of cellulose films permeable to water, the films are first soaked in a solution of one of the reacting salts, then doubled and bathed in a solution of the other reacting salt. As a result of the doubling only one surface of the film is exposed to the second bath.—W. G.

Light rays, cathode rays, Röntgen rays or the like; Process of and apparatus for treating ——. R. Bengough. E.P. 165,790, 13.9.21.

When a beam of light passes through another beam, the second set of rays acts like a filter, influencing the complementary colour in the first. By means of a tube having side windows, all kinds of rays can be treated.—W. C.

Photographic films with a carrier permeable to water. J. E. Brandenberger. E.P. 179,500, 26.1.21.

Films of viscose or the like which are permeable to water are first thoroughly moistened with water. Ordinary photographic emulsions with a gelatin base can then be coated very uniformly on the films. —W. C.

Photographic papers; Means [drying apparatus] for use in manufacture of ——. J. W. Davies. E.P. 179,832, 25.5.21.

The paper, after being chemically treated on one side only, passes through a drying chamber without being touched on its coated side. The chamber is of approximately cylindrical shape and is heated from the inside; the paper enters from the coating machine and passes round the chamber, and emerges again close to the entrance. The apparatus is specially suitable for ferro-prussiate paper.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Detonating and priming mixtures; Analysis of ——. C. A. Taylor and W. H. Rinkenbach. U.S. Bureau of Mines Tech. Paper 282, 1922, 33 pp.

Lists of inorganic and organic materials used in detonating compositions are given and methods of removing the charges from detonators. Details are given of the analysis of mixtures of mercury fulminate and potassium chlorate, and of the analysis of mixtures containing trinitrotoluene, tetryl, nitromannitol and nitrocellulose. Methods are also given for the analysis of priming compositions containing chlorate and picric acid, lead azide and tetryl, and lead azide and trinitrotoluene. Lists are given of inorganic and organic materials used in primer compositions and methods are given for the analysis of single primers and typical priming mixtures, including complex non-corrosive mixtures. —H. C. R.

Patents.

Explosive. J. R. Mardick, Assr. to Acheson Graphite Co. U.S.P. 1,415,889, 16.5.22. Appl., 29.7.21.

Black blasting powder is provided with a uniform glaze of finely-divided, amorphous graphite produced by electrical means whereby a product characterised by improved covering and moisture-resisting qualities, uniformity of carbon and mineral content, increased sensitiveness, uniform progression of burning and velocity of explosion is obtained. —L. A. C.

Primer for small-arms ammunition. H. T. Peck, Assr. to The Peters Cartridge Co. U.S.P. (A) 1,416,121, (B) 1,416,122, and (C) 1,416,123, 16.5.22. Appl., 20.7.21.

A priming composition contains trinitroresorcinol, a thiocyanate, and (A) potassium chlorate and normal lead trinitroresorcinol, (B) an oxidising agent and diplumbic trinitroresorcinol, and (C) an oxidising agent and mercury fulminate.—L. A. C.

XXIII.—ANALYSIS.

Gasometer for providing a continuous current of gas. R. Schleipen. Chem.-Zeit., 1922, **46**, 406.

Two bottle-shaped reservoirs are connected at the bottom by a short tube and at the top by a single neck which is provided with a four-way tap. The bores of the latter are so arranged that a supply of gas from a cylinder or other source of supply enters one reservoir, which is filled previously with water or other liquid; the water passes through the tubulure into the other reservoir, discharging gas from this through the other bore of the tap to the place where it is required. As soon as all the water has been forced into the second reservoir, the tap is turned so that the operation proceeds in the reverse manner. The water or other liquid simply passes from one reservoir to the other, alternately, and when once it has been saturated with the gas, solubility of the latter in the water does not affect the measurement of the gas.—W. P. S.

Gas analysis; The absorption meter, an apparatus for ——. L. Moser. Z. anorg. Chem., 1922, **121**, 313—315.

A simplified form of the apparatus previously employed for the gravimetric estimation of hydrogen phosphide (J., 1922, 327 A) is described. The apparatus has been tested and gives good results in the estimation of sulphur dioxide, cyanogen, hydrogen cyanide, silicon fluoride, the hydrides of arsenic and antimony, ozone, and chlorine. It is unsuitable for gases which require an absorption liquid affected by the air, *e.g.*, for the absorption of carbon dioxide by baryta water.—W. T.

Calorimetry; Maintenance of the adiabatic condition in ——. F. Barry. J. Amer. Chem. Soc., 1922, **44**, 899—937.

A closed calorimeter is described which may be used for the determination of heat changes which accompany slow chemical reactions. The calorimeter is used in a thermostat and all conducting parts which are in contact with the surrounding air are surrounded by air gaps. The accuracy with which the heat content of the calorimeter can be maintained is ±0·5 cal. in ten hours. (*Cf.* J.C.S., July.)—J. F. S.

Surface tension; Determination of —— from the maximum pressure in bubbles. S. Sugden. Chem. Soc. Trans., 1922, **121**, 858—866.

A simple form of apparatus for the measurement of surface tension by the method of maximum pressure in bubbles consists of a narrow cylindrical vessel immersed in a thermostat and fitted with a rubber stopper carrying two tubes, one 3 mm. in diameter with a sharp inner edge, the other drawn out to a fine capillary. A side branch connects this vessel with a water pressure gauge and a mercury suction bulb the capillary of which regulates the rate of formation of bubbles in either of the open tubes in the cylindrical vessel. Measurements of the surface tension of water and benzene made by this means show close agreement with values obtained by the method of capillary rise.—P. V. M.

Indicator; Use of a universal ——. F. H. Carr. Analyst, 1922, **47**, 196—197.

The indicator consists of a mixed solution of methyl red, naphtholphthalein, and phenolphthalein, to which are added bromothymol blue or thymolphthalein and cresolphthalein or cresol red; such a mixture exhibits a series of colour changes over a range of p_H from 3 to 11.—W. P. S.

Ultra-violet light; Use of —— in analysis. A. F. Kitching. Analyst, 1922, **47**, 206—207.

The fluorescent effects produced by the action of ultra-violet light may be used to distinguish one substance from another; for instance, cotton is readily distinguished from wool or silk, casein from gelatin, certain kinds of paper from others, etc. Acetone can be detected in alcohol, 1% giving a distinct effect. With quinine, 1 in one hundred million parts of water, with uranine, 1 in one thousand million, and with æsculin, 1 in ten thousand million, distinct fluoresence is shown under favourable conditions.—W. P. S.

Arsenic, antimony, and bismuth; Invisible "mirrors" [in the detection] of ——. H. Scheucher. Monatsh., 1921, **42**, 411—420.

Bettendorff's reaction provides an extremely delicate microchemical test for arsenic. Into a fine capillary tube are introduced about 2 cub. mm. of the solution to be tested and four times as much of a solution of 1 pt. of stannous chloride in 2 pts. of fuming hydrochloric acid. One end of the tube is sealed to a point and it is then heated for a short time in a bath of boiling amyl alcohol. The tube is centrifuged and the arsenic appears in the point of the tube as a brown precipitate. In this way 0·01γ of arsenic (γ=0·001 mg.) can be detected at a dilution of 1 in 250,000. The test is not interfered with by antimony, tin, lead, copper, or cadmium. The magnesium ammonium arsenate test, applied microchemically, is only sensitive to 0·1γ. The Marsh test, using Lockemann's method (Z. angew. Chem., 1905, **18**, 416) is sensitive to 0·1γ of arsenic. With less arsenic the "mirror" becomes invisible but if the tube which should contain the mirror is treated with bromine vapour to oxidise the arsenic and then subjected to the above test, much smaller quantities of arsenic can be detected. Invisible mirrors of antimony can also be detected by applying the flame test described by Paneth (Ber., 1918, **51**, 1739). The supposed mirror is dissolved with a drop of nitric acid which is then transferred to a piece of pure ignited calcium carbonate held in a platinum loop. When this is then placed in the edge of a hydrogen flame, a sky-blue colour shows the presence of antimony. This reaction is sensitive to 0·001γ. The reaction can also be applied to a bismuth mirror prepared from bismuth hydride as described by Paneth (*loc. cit.*). Bismuth gives a cornflower blue luminescence in the hydrogen flame. (*Cf.* J.C.S., July.)—E. H. R.

Microanalysis; Pregl's ——. F. Holtz. Ber., 1922, **55**, 1496—1497.

The use of a bomb furnace in the estimation of halogen and sulphur is avoided by placing the bomb tubes in brass tubes, closed at one end and stoppered at the other, which are heated in the vapour of boiling diphenylmethylamine, b.p. 205° C. The estimation of nitrogen in difficultly combustible substances is effected in silica tubes which are filled in the following order: asbestos plug, oxidised copper wire (7 cm.), reduced copper wire (11 cm.), asbestos plug, copper oxide powder mixed with the substance and a little potassium chlorate (4 cm.), oxidised copper wire (5 cm.). The tube is supported at either end on gutters lined with asbestos in such a manner that the portion of it which contains the reduced copper is exposed to the direct heat of the burner. This part of the tube is doubly protected on its upper side. After displacement of the air by carbon dioxide, the reduced copper is raised to a white heat and, after a second passage of carbon dioxide, the heating of the remainder of the tube is effected very gradually in the direction towards the reduced copper. In this manner, the decomposition of oxides of nitrogen is effected with certainty. Substances may be dried conveniently in a hollow copper cube the walls of which are 1 cm. thick and 6·5 cm. long internally.—H. W.

Copper and iron; Estimation of —— in the presence of one another by means of trivalent titanium. W. M. Thornton, jun. J. Amer. Chem. Soc., 1922, 44, 998—1001. (*Cf.* J., 1921, 281 A.)

A MIXTURE of cupric and ferric sulphates in less than 100 c.c. of water is acidified with 10 c.c. of sulphuric acid (1:1), cooled to 15° C., and treated with a quantity of 10% ammonium thiocyanate solution (2·5—5·0 c.c.) depending on the amount of copper anticipated. The solution is titrated with a standard solution of titanium trisulphate until the pink colour just vanishes. The titre gives the sum of the copper and iron present. The whole is heated to incipient ebullition to coagulate the cuprous thiocyanate, cooled and filtered. The precipitate is thoroughly washed with cold water, and the filtrate and washings cooled to 15° C. The solution has by this time probably become pink again due to air oxidation. If so, the colour is bleached by the careful addition of titanium trisulphate and sufficient silver nitrate (2·5—5·0 c.c. of 25% solution) is added to precipitate the whole of the thiocyanate. The ferrous iron is then titrated with a standard solution of potassium permanganate. The method is accurate and trustworthy, but the precaution of testing the titanium solution for iron must be taken and if such is found the permanganate titre corrected for this amount. —J. F. S.

Arsenic; Qualitative reactions for ——. I. M. Kolthoff. Pharm. Weekblad, 1922, 59, 334—350.

THE reaction of Mayençon and Bergeret (J. Chem. Soc., 1874, 1008; reduction to arsine and detection with mercuric chloride paper), under suitable conditions will detect 0·001 mg. arsenic in 1 c.c. That of Bougault (reduction to free arsenic by means of hypophosphite) will detect 0·002 mg. (*Cf.* J.C.S., 1922, ii., 455.)—S. I. L.

Arsenic reaction; Aluminium for the ——. G. Romijn. Chem. Weekblad, 1922, 19, 177—179.

IN the Mayençon and Bergeret reaction (*cf.* Kolthoff, *supra*) aluminium is more suitable than zinc. (*Cf.* J.C.S., 1922, ii., 455.)—S. I. L.

Antimony; Detection of —— in analysis. T. Sabalitschka and H. Schmidt. Ber. deuts. Pharm. Ges., 1922, 32, 132—135.

To obviate the necessity of using platinum, antimony may be detected in the solution of the sulphides of antimony and tin in concentrated hydrochloric acid as ordinarily obtained in the course of analysis, by diluting a portion of this solution with an equal volume of water, adding a piece of arsenic-free zinc to the cooled liquid, in a test tube, and testing the issuing gases with a piece of filter paper freshly moistened with a 10% solution of silver nitrate. In presence of considerable amounts of antimony the paper immediately becomes black on the under side, or within 2 mins. with only minute amounts. A slight brownish coloration is not to be taken into account; and it is important that the silver nitrate solution is not too concentrated, otherwise small amounts of antimony hydride may cause only a brownish-yellow coloration instead of black as is obtained with dilute silver solutions.—G. F. M.

Rock dust in air; The sugar-tube method of determining ——. A. C. Fieldner, S. H. Katz, and E. S. Longfellow. U.S. Bureau of Mines, Tech. Paper 278, 1921. 40 pages.

A DETERMINATION of the dependence of the efficiency of sugar filters for very fine particles in air upon such factors as the size of filter tube, depth of sugar layer, size of sugar granules, and presence of moisture. Two methods of testing were employed. In one a suspension of tobacco smoke or silica dust was passed through the filter and the amount of smoke or dust present in the stream prior to and after passing the filter ascertained optically by means of the Tyndall effect. In the other method, the filtering efficiency was determined gravimetrically. The following results were obtained. The filtering efficiency of sugar tubes increases with the diameter of the tubes, and decreases with increasing velocity of air. Sugar wetted with water or 35% alcohol and tested as regards filtering efficiency with silica dust, showed an average increase of 4% for water and 5% for the alcohol by the optical method. The filtering efficiency of the sugar increased with increasing fineness. The efficiency of a layer of granulated sugar 1 inch deep, tested by means of tobacco smoke was 14%, while the efficiency of a layer 4 inches deep was 38%. Tests by the gravimetric method with silica dust showed higher efficiencies than tests by the optical method. For determining the filtering efficiencies of sugars, blank tests must be run for every lot. Tests by the gravimetric method showed filtering efficiencies ranging from 70% to 95%. A tube containing 65 g. of pulverised sugar, 48- to 150-mesh size, possessed an efficiency greater than 92% against tobacco smoke for 15 minutes.—J. S. G. T.

Ammoniacal nitrogen in nitrogenous organic substances; Determination of —— and particularly in proteins and their products of hydrolysis. J. Froidevaux. Comptes rend., 1922, 174, 1238—1240.

To 15 c.c. of the solution under examination 35 c.c. of 60% aqueous sodium hydroxide is added, and air, carefully freed from ammonia, is bubbled through at the ordinary temperature at the rate of 150—200 bubbles per minute. The issuing air is passed through a known volume of standard acid, which is renewed from time to time. The acid is titrated and the amount of ammonia absorbed is plotted against the time. The resulting curve consists of a line sharply inclined to the time axis and one slightly inclined to this axis, the two being joined by a curved portion. The first line corresponds to ammoniacal nitrogen and the second to ammoniacal nitrogen coming from the slow decomposition of protein or amino-acids, the curved portion being a combination of the two. The two straight lines are produced and their junction represents the total ammoniacal nitrogen originally present as such in the sample.—W. G.

Tyrosine, tryptophan, and cystine; Colorimetric methods for the separate estimation of —— in proteins. O. Folin and J. M. Looney. J. Biol. Chem., 1922, 51, 421—434.

CERTAIN defects in the method of Folin and Denis (J. Biol. Chem., 1912, 12, 239) for the estimation of tyrosine are remedied, and an extension is made to include the separate estimation of tryptophan and cystine. When tryptophan is to be estimated, the protein is hydrolysed by means of barium hydroxide to avoid loss due to humin formation. In the case of cystine, which is decomposed by boiling alkalis, acid hydrolysis is used. For the estimation of tyrosine and tryptophan, the hydrolysate, which must contain between 3·5% and 7·5% of sulphuric acid, is filtered from barium sulphate, and tryptophan is precipitated from an aliquot part of the filtrate by the addition of Hopkins and Cole's mercuric sulphate reagent (a solution containing 10% of mercuric sulphate and 5% of sulphuric acid). After separation by centrifuging, tyrosine is estimated colorimetrically in the supernatant liquid by means of Folin and Denis's phenol reagent in the presence of sodium carbonate and sodium cyanide.

The estimation of tryptophan is made similarly in the solution obtained by dissolving the mercuric sulphate precipitate in sodium cyanide. In the case of cystine, sodium carbonate is added to the hydrolysate, and the cystine is reduced by means of sodium sulphite. The colour produced on addition of the uric acid reagent is then compared with a standard. Results of the application of the method to a number of proteins are given. (The phenol reagent is prepared by boiling 15 g. of molybdic oxide and 10 g. of sodium hydroxide in 200 c.c. of water, adding 100 g. of sodium tnugstate, 50 c.c. of 85% phosphoric acid, 100 c.c. of concentrated hydrochloric acid, and enough water to bring the volume to 800 c.c., boiling the mixture for 10 hrs. in a flask fitted with a reflux condenser, then removing the condenser, adding a few drops of bromine to decolorise the solution, boiling off the excess of bromine, cooling, filtering, and diluting to 1 litre.)

Patent.

Carbon dioxide and combustible gases containing carbon; Means for quantitative detection of ——. Victoria Falls and Transvaal Power Co., Ltd., and W. O. Andrews. E.P. 179,696, 18.2.21.

Carbon dioxide present in gaseous mixtures or produced by combustion of the latter is determined by absorption in an aqueous solution containing a coloured indicator and subsequent comparison of the colour with standard tints.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given: they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Boberg, Testrup, and Techno-Chemical Laboratories. Drying moist materials. 16,818. June 17.

British Thomson-Houston Co. (General Electric Co.). Obtaining visible temperature records. 17,014. June 20.

Dickson and Mann, Ltd., and Thornton. Apparatus for wet separation of granular materials. 16,859. June 19.

Dunlop (Reid). Furnaces. 16,637. June 15.

Hase. Pyrometers. 17,461. June 24.

Knowles. Hydro-extractors. 17,194. June 22.

Mauclère. Plant for manipulating liquids. 16,945. June 19. (Fr., 20.6.21.)

Morison. De-aerating or degasifying liquids. 16,479. June 14.

Nordström. Drying-plants. 17,179. June 21.

Powdered Fuel Plant Co. Pulverising or grinding apparatus. 17,125. June 21. (Fr., 8.3.22.)

Power Specialty Co. Furnaces for oil stills, superheaters, etc. 16,740. June 16. (U.S., 2.7.21.)

Prior. Agitators and mixing-devices. 16,552. June 15.

Smith. Furnaces. 17,008. June 20.

Sweetland. Distillators. 16,943. June 19.

Complete Specifications Accepted.

34,919 (1920). Bohrmann. Evaporation of liquids. (181,406.) June 28.

167 (1921). Chenard. Apparatus for fractional distillation. (156,218.) June 21.

662 (1921). Bramwell. Filtration of liquids. (181,044.) June 21.

3965 (1921). Thorssell and Troell. Agglomerating pulverous material. (181,413.) June 28.

6863 (1921). Brown and Coldrey. Drying-apparatus. (181,082.) June 21.

7115 (1921). Dunlop Rubber Co. (Lewis and Green). Apparatus for drying materials carrying a volatile inflammable solvent and recovering the solvent. (181,100.) June 21.

7457 (1921). Mauss. Vacuum filtration of colloidal matter from liquid mixtures. (181,123.) June 21.

7818 (1921). Heylandt Ges., and Unruh. Cooling and liquefying air and other gases. (167,144.) June 21.

8019 (1921). Metallbank u. Metallurgische Ges., and Gensecke. Operation of evaporating plants heated with compressed vapours. (181,482.) June 28.

8296 (1921). Merz and McLellan, Weeks, and Baker. Heat interchangers. (181,501.) June 28.

8303 (1921). Steigner. Kilns. (181,502.) June 28.

11,860 (1921). Reynolds, Dickin, and Kenyon. Separation or grading of powdered materials and treatment thereof by air or other gases or vapours. (181,560.) June 28.

25,247 (1921). Lodge Fume Co. *See* XI.

27,841 (1921). Powdered Fuel Plant Co. Pulverising or grinding apparatus. (181,290.) June 21.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

British Thomson-Houston Co. (General Electric Co.). Filaments for electric incandescent lamps. 17,358. June 23.

Brown. Retorting shale oil. 16,524. June 14.

Browne. Carbonisation and distillation of coal etc. 16,816. June 17.

Elektrizitätswerk Lonza. Purification of acetylene. 16,389. June 13. (Switz., 18.8.21.)

Gas Research Co. Gas-producer system. 17,372. June 23. (U.S., 30.7.21.)

General Electric Co. Manufacture of filaments for electric incandescent lamps. 17,161. June 21. (Ger., 13.7.21.)

General Motors Research Corp. Fuels. 17,373. June 23. (U.S., 15.4.22.)

Higginbotham. Production of hydrocarbons. 16,364. June 13.

Munn, and Whitehall Petroleum Corp. Apparatus for chemically treating mineral oil products. 17,158. June 21.

Power Specialty Co. 16,740. *See* I.

Tooley and Tooley. Retorts for distilling coal etc. 16,621. June 15.

Whitehall Petroleum Corp. (Greenspan). Purification of hydrocarbons. 17,273. June 22.

COMPLETE SPECIFICATIONS ACCEPTED.

34,419 (1920). Persch. Treatment of petroleum and other hydrocarbon oils. (181,034.) June 21.

34,473 and 36,183 (1920) and 2372 (1921). Rigby. Drying peat etc. (181,035.) June 21.

34,874–5 (1920). Helps. Gas manufacture. (181,403–4.) June 28.

1510 (1921). Jackson. Improvement of inferior brown coals etc. (157,794.) June 21.

1511 (1921). Jackson. Production of a fuel for use as a gas-coal substitute. (157,795.) June 21.

2978 (1921). Haddan (Torfverwertungs-ges. Pohl u. Von Dewitz). Dry distillation and coking of raw peat etc. (158,513.) June 28.

4642 (1921). Cumberland Coal and Chemicals, Ltd., and others. *See* VII.

7139 (1921). Tulloch and Smith. Treatment of gas. (181,102.) June 21.

7557 (1921). Ginet. Treatment of bituminous shales. (181,126). June 21.

10,828 (1921). Trent Process Corp. *See* XII.

13,180 (1921). Booer, and District Chemical Co. Materials for purifying acetylene. (181,571.) June 28.

14,058 (1922). Helps. Gas manufacture. (181,665.) June 28.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Ellis, Goskar, Kissock, and Vivian. Treatment of tar etc. 16,704. June 16.

Higginbotham. 16,384. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of azo dyestuffs. 17,272. June 22.

Ransford (Cassella u. Co.). Production of dyestuffs containing sulphur. 16,927. June 19.

COMPLETE SPECIFICATION ACCEPTED.

14,161 (1921). Johnson. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Briggs, Yorke, and British Cellulose and Chem. Manuf. Co. Apparatus for producing textile products. 16,597. June 15.

Dreaper. Apparatus for filtering solutions for making artificial silk etc. 17,186. June 22.

Erikson. Soda recovery process in sulphate paper-pulp manufacture. 16,687. June 16.

Haigh. Carbon etc. coated papers. 17,456. June 24.

Lilienfeld. Manufacture of cellulose derivatives. 16,307, 16,308, 16,310. June 12. (Austria, 13.6.21.)

Lilienfeld. Manufacture of artificial threads and textiles. 16,309. June 12. (Austria, 13.6.21.)

Marriott. Manufacture of artificial silk. 16,406. June 13.

Ott. Composition for coating celluloid films etc. 17,173. June 21.

Roberts. Steam-heated drying cylinders for fabrics etc. 16,967. June 20.

COMPLETE SPECIFICATIONS ACCEPTED.

852 (1921). Harnist. Treatment of crude cellulose. (156,777.) June 28.

8282 (1921). Carpmael (Bagley and Sewell Co.). Manufacture of paper. (181,140.) June 21.

27,245 (1921). Tomlinson-Haas, Ltd., and Smith. Apparatus for drying textile materials. (181,286.) June 21.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Auchinachie. Waterproofing fabrics. 17,338. June 23.

Dunnachie. Washing, bleaching, and/or dyeing. 16,843. June 19.

Halter. Dyeing-machines etc. 16,295. June 12.

Kent and Tither. Mercerising, bleaching, dyeing, or finishing cloth. 17,333. June 23.

Lilienfeld. Dyeing alkylcelluloses. 16,306. June 12. (Austria, 13.6.21.)

Wallis. Calico-printing machines. 17,086. June 21.

COMPLETE SPECIFICATIONS ACCEPTED.

8591 (1921). Lee and Sons, and Pinder. Machines for dyeing hanks of yarn etc. (181,506.) June 8.

11,272 (1921). Thornber and Henshilwood. Machines for bleaching, dyeing, finishing, etc. fabrics. (181,552.) June 28.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Baumgartner. Manufacture of chromate of soda. 16,651. June 15.

Chem. Fabr. Griesheim Elektron. Production of basic magnesium carbonate. 16,271. June 12. (Switz., 11.6.21.)

Chem. Fabr. Weissenstein. Manufacture of hydrogen peroxide. 17,381. June 23. (Austria, 3.8.21.)

Erikson. 16,681. *See* V.

Hurter. Manufacture of alumina from aluminium sulphate. 16,640. June 15.

Jacobson. Process of making anhydrous metallic chlorides. 16,197. June 12. (U.S., 10.6.21.)

Johnson (Badische Anilin u. Soda Fabr.) Production of formic acid derivatives. 17,032. June 20.

Jones. 16,528. *See* XIII.

Robinson. Purification or refining of sulphur. 16,289. June. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

4419 (1921). Deuts. Gold- u. Silber-Scheideanstalt, and Liebknecht. Manufacture of prussic acid. (181,058.) June 21.

4642 (1921). Cumberland Coal Power and Chemicals, Ltd., West, and Jaques. Production of hydrogen. (181,062.) June 21.

7898 (1921). Stubbs. Bleaching stained earthy minerals. (181,132.) June 21.

8090 (1921). Cederberg and Backstrom. Catalytic oxidation of ammonia. (181,486.) June 28.

9025 (1921). Chem. Fabr. Griesheim-Elektron, and Reitz. Rendering calcium hypochlorite stable. (181,153.) June 21.

10,189 (1921). L'Air Liquide. Synthesis of ammonia. (161,195.) June 21.

19,142 (1921). Kelly. Production of phosphoric acid. (181,255.) June 21.

VIII.—GLASS; CERAMICS.

APPLICATION.

British Thomson-Houston Co. (General Electric Co.). Coating glass surfaces. 17,165. June 21.

COMPLETE SPECIFICATION ACCEPTED.

7149 (1921). Hailwood. Glass manufacture. (181,434.) June 28.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Brereton. Manufacture of compositions for paving, roofing, etc. 17,249. June 22.

Claxton. Manufacture of road paving material. 17,354. June 23.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Clerc and Nihoul. Extraction of tin. 16,636. June 15. (Fr., 15.6.21.)

Ellsworth. Recovery of zinc from complex ores. 17,159. June 21. (U.S., 12.7.21.)

Fertigguss Ges. Zinc alloy for casting in dies or chills. 17,244. June 22. (Ger., 25.6.21.)

General Electric Co. 17,161. *See* II.

General Electric Co. Transformation of crystal structure of drawn wires of tungsten etc. 17,162. June 21. (Ger., 13.7.21.)

General Electric Co. Manufacture of tungsten etc. 17,163. June 21. (Ger., 13.7.21.)

Hadfield. Manufacture of steel. 16,948. June 19.

Herman. Coating and treating materials having an iron base. 17,260. June 22.

Markham, and Staveley Coal and Iron Co. Blast-furnace slag. 16,291. June 12.

Marks (Electro Metallurgical Co.). Zirconium alloys. 17,261. June 22.

Metzl. Treatment of gold- and silver-bearing antimony ores. 16,695. June 16.

Mitsubishi Zosen Kabushiki Kaisha. Alloy for turbine blades. 17,263. June 22. (Japan, 28.7.21.)

Saltrick. Alloy castings. 17,019. June 20.

Wild and Wild. Manufacture of alloy steels and irons. 17,128. June 21.

Wood and Wood. Cupolas. 17,413. June 24.

COMPLETE SPECIFICATIONS ACCEPTED.

34,102 (1920). Andrews. Rustproofing articles of iron and steel. (181,399.) June 28.

34,707 (1920). White (Valley Holding Corp.). Manufacture of magnetic alloy sheets. (181,401.) June 28.

4230 (1921). Rosthorn. Manufacture of copper alloys. (158,882.) June 21.

7482 (1921). Stockport Furnaces, Ltd., Duckworth, and Mead. Gas- or oil-heated furnaces of the crucible type. (181,452.) June 28.

7906 (1921). Ampère Ges., Rothe, and Diefenthaler. Manufacture of molybdenum or iron-molybdenum alloys. (160,143.) June 28.

16,163 (1921). Elmore, and Chemical and Metallurgical Corp. Treatment of lead-bearing mattes. (181,239.) June 21.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Fuller, and Fuller's United Electric Works. Galvanic batteries. 17,150. June 21.

Jones. Electric furnace. 16,351. June 13.

Nyberg. Galvanic cells. 16,301. June 12. (Sweden, 28.3.22.)

Stephens (Grundy). Ozonisers. 16,925. June 19.

COMPLETE SPECIFICATIONS ACCEPTED.

20,059 (1921). Cheney. Storage battery electrolyte. (181,630.) June 28.

25,247 (1921). Lodge Fume Co. (Metallbank u. Metallurgische Ges.). Insulator for electrodes of electrical gas purifiers. (181,284.) June 21.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Eppenberger. Rendering fat-containing granular products impalpable. 16,623. June 15. (Ger., 19.4.22.)

Glabau and Travis. Emulsions and method of preparing same. 17,369. June 23. (U.S., 17.3.22.)

Levey. Continuous deodorisation of edible oils and fats. 16,213. June 12.

Rooke. Extraction of tallow, grease, oil, etc. from bones, fish, skins, etc. 17,458. June 24.

Rooke. Digesters, retorts, and drying-apparatus for extracting fat. 17,459. June 24.

COMPLETE SPECIFICATIONS ACCEPTED.

1322 (1921). Du Pont de Nemours and Co. Deodorising blown or polymerised vegetable or animal oils. (157,401.) June 28.

6787 (1921). Douglas and Sons, and Nicol. Treatment of edible fats. (181,077.) June 21.

8908 (1921). Gleitz. Removing free acids from glycerides. (181,509.) June 28.

10,828 (1921). Trent Process Corp. Separation of oils. (167,738.) June 21.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

British Thomson-Houston Co. (General Electric Co.). Plastic compositions. 17,015. June 20.

Consort. f. Elektrochem. Ind. Improving artificial resins. 17,380. June 23. (Ger., 29.6.21.)

Delclève and Dessemond. Manufacture of Prussian blue. 16,603. June 15. (Fr., 16.6.21.)

Exley, McGregor, and Rimmer. Paint etc. 16,200. June 12.

Jones. Manufacture of a zinc-oxide substance. 16,528. June 14.

Moosman and Trevor. Manufacture of paints. 16,270. June 12.

Ott. Waterproofing composition. 17,174. June 21.

COMPLETE SPECIFICATIONS ACCEPTED.

13,472 (1921). Dreyfus. Manufacture of artificial resin products. (181,575.) June 28.

14,161 (1921). Johnson (Badische Anilin u. Soda Fabr.). Manufacture of pigment-colours. (181,584.) June 28.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Carpmael (Bayer u. Co.). Treatment of caoutchouc etc. 16,926. June 19.

Fall. Curing rubber latex. 17,027. June 20.

Lennard. Incorporating rubber with tar. 17,046. June 20.

Marter. Treatment of indiarubber etc. 17,038. June 30.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Hell. Tanning skins and hides. 17,396. June 23.

Moeller. Bating and liming hides etc. 16,516. June 14.

Rooke. 17,458. *See* XII.

Complete Specifications Accepted.

288 (1921) Chem. Fabr. u. Asphaltwerke. Tanning materials. (156,254.) June 21.

626 (1921). Niessen. Extraction of glue by means of water. (156,645.) June 28.

6221 (1921). Carmichael and Ockleston. Tanning. (181,067.) June 21.

XVI.—SOILS; FERTILISERS.

Complete Specifications Accepted.

6434 (1921). Lo Monaco. Fertilisers. 159,481. June 21.

18,582 (1921). Niedenzu. Manufacture of artificial nitrogenous fertilisers. (166,887.) June 28.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specifications Accepted.

11,767 (1921). Courtaulds, Ltd., and Stokes. Manufacture of compounds or mixtures of starch and starchy matter and sulphuric acid. (181,197.) June 21.

11,772 (1921). Courtaulds, Ltd., and Lloyd. Manufacture of compounds or mixtures of starch and sulphuric acid. (181,198.) June 21.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specifications Accepted.

6636 and 28,355 (1921). Jensen (Corby). Treating and preparing yeast. (181,076 and 181,293.) June 21.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Brettell (Lepetit). Manufacture of pectin substances for food preparations. 16,515 and 17,076. June 14 and 21.

Glabau and Travis. Baking compounds. 17,370. June 23. (U.S., 24.3.22.)

Glabau and Travis. Vitamin-bearing products. 17,371. June 23. (U.S., 25.3.22.)

Hepburn. Softening water. 17,057. June 20.

Loring. Manufacture of flour. 16,960. June 20.

Martin. Food products. 16,405. June 13.

Torley. Filtering-material for water etc. 16,251. June 12.

Complete Specifications Accepted.

12,260 (1920). Watson, Jones, and Woodlands, Ltd. Manufacture of bread. (181,397.) June 28.

6474 (1921). Waite and Boldy. Apparatus for separating the solid matter from trade effluent etc. (181,071.) June 21.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Best and Collip. Preparation of extracts of pancreas. 16,360. June 13.

Blagden, and Howards and Sons. Manufacture of thymol. 16,632. June 15.

Consort. f. Elektrochem. Ind. Manufacture of esters and ethers of ethylideneglycol and vinyl alcohol. 16,898. June 19. (Ger., 23.6.21.)

Corbett and Habershon. Preparation of vaccines. 16,932. June 19.

Complete Specification Accepted.

17,799 (1921). Napp (Hoffmann-La Roche & Co.). Manufacture of CC-isopropylallylbarbituric acid. (181,247.) June 21.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Dehn (Pyrocolour Corp.). Colour photography. 16,242. June 12.

Complete Specifications Accepted.

6901 (1921). Luboshey. Sensitive plates and films for X-ray photography. (181,087. June 21.

7646 (1921). Hall. Machines for sensitising papers and other fabrics. (181,460.) June 28.

XXIII.—ANALYSIS.

Applications.

Newman. Means for detecting and indicating presence of choke-damp and fire-damp in mines etc. 17,178. June 21.

Sandy and Turquand. Apparatus for detecting presence of inflammable etc. gases. 16,231. June 12.

Turquand. Means for indicating the presence of gas or of acid or alkaline properties in air, water, etc. 17,357. June 23.

I.—GENERAL; PLANT; MACHINERY.

Membrane filters. **Jander.** *See* **XXIII.**

PATENTS.

Chemical and physical operations; Apparatus for use in connection with ——. A. T. Stuart and G. N. Middleton, Assrs. to The Toronto Power Co., Ltd. U.S.P. 1,417,585, 30.5.22. Appl., 5.7.17. Renewed 27.12.20.

An apparatus for carrying out reactions at high temperatures and pressures is constructed as a closed chamber heated by electric currents in the walls, which are of high electrical resistance and prevented from bursting by pressure-resisting means surrounding them.—B. M. V.

Dryer. F. A. Martoccio. U.S.P. 1,418,010, 30.5.22. Appl., 2.8.20.

A casing is divided by vertical partitions into a number of drying chambers to which air is delivered by a fan mounted in a chamber at one end of the casing. The partitions adjacent to the fan chamber are spaced from the top and bottom of the casing to form air-circulating passages and the drying chamber remote from the fan chamber is formed with a passage between a partition and the end wall of the casing. The upper air passage is fitted with a baffle which compels the air to pass downwards in the drying chamber remote from the fan, and the wall of this chamber is provided with exhaust ports. —H. H.

Dehydrating material; Method of and apparatus for ——. F. Maus, Assr. to S. J. Spoelstra. U.S.P. 1,418,386, 6.6.22. Appl., 3.2.21.

The apparatus consists of an air-cooling chamber, a dehydrating chamber, and connecting conduits, and means for circulating air through the system. —A. de W.

Separation of liquids from solids [drying solids]; Process and apparatus for ——. H. Terrisse and M. Lévy. G.P. 351,216, 27.4.20. Conv., 25.3.20.

The material to be dried is heated in a container by means of a stream of air or gas that has previously been heated to a temperature just sufficient to distil off the liquid without having any injurious effect on the solid. Means are provided for recovering the liquid evaporated.—A. R. P.

Fractional condensation; Process of ——. J. F. W. Schulze, Assr. to The Barrett Co. U.S.P. 1,418,885, 6.6.22. Appl., 21.6.19.

A fraction of a mixed vapour is condensed and is concentrated by heat interchange and dephlegmation with the vapours generated from the fraction by reheating it to a higher temperature than that at which it was in equilibrium with the mixed vapour. The heat is transferred from the mixed vapour to the fraction without contact between the two.—H. H.

Gas-fired shaft furnace. F. and K. Meiser. G.P. (A) 351,195, 8.2.21, and (B) 351,196, 22.2.21.

(A) The furnace is provided with hot air flues leading from the cooling shaft to the burners. Hot air is sucked from the shaft by injecting compressed air, that has previously been heated by the waste gases from the furnace, into these flues, and this air is used for the combustion of the gas used in firing the furnace. The gas also may be preheated by the waste furnace gases, and by preheating both air and gas, limestone may be calcined with low-grade producer gas. (B) The gas used in the furnace is passed through an iron recuperator built in the preheating zone of the furnace and heated by the waste gases, and the issuing hot gas is burnt by means of the hot air drawn out of the shaft as in (A). If necessary the fuel gas may be supplied under pressure, which is not possible with a masonry recuperator.—A. R. P.

Calcining furnace with indirect heating. C. Roschmann. G.P. 351,314, 10.5.21. Addn. to 344,363 (J., 1922, 164 A).

The combustion chambers and air-circulating flues of the furnace are constructed of a series of ribbed plates one above the other, the edges of which are provided with raised ribs to keep them apart. To increase further the working surface the combustion chambers and flues are filled with hollow permeable bodies through which the heating gases and air pass.—A. R. P.

Liquids; Non-corroding and non-freezing ——. Miller Reese Hutchison, Inc., Assees. of A. Z. Pedersen. E.P. 170,274, 23.8.21. Conv., 13.10.20

See U.S.P. 1,405,320 of 1922; J., 1922, 206 A

Drying materials; Process of and apparatus for ——. E. M. Bassler. E.P. 180,394, 11.2.21.

See U.S.P. 1,374,874 of 1921; J., 1921, 376 A.

Separating aqueous and other vapours from fluids and solids; Process for —— *and for preparing dilute sulphuric acid.* O. Maass. U.S.P. 1,417,618, 30.5.22. Appl., 15.4.18.

See E.P. 159,054 of 1919; J., 1921, 248 A.

Liquids; Process for evaporating ——. E. Morterud. U.S.P. 1,418,197, 30.5.22. Appl., 15.10.18.

See E.P. 120,205 of 1918; J., 1919, 853 A.

Heat-exchanging apparatus. Allgem. Elektrizitäts-Ges., and F. Münzinger. E.P. 180,025, 14.2.21.

Furnaces; Oil-fired ——. L. Krause. E.P. 180,176, 23.4.21.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Separation of the constituents of banded bituminous ——. A. E. Findley and R. Wigginton. Fuel, 1922, 1, 106—107.

By employing a combined method of sifting and classification according to density, a sample of coal from the Kirkby Top Hards seam was separated into three main fractions, *viz.*, (1) coal with density less than 1·3, passing through a 30-mesh sieve but being caught on a 60-mesh sieve, and containing 1·55% of ash; (2) coal of density greater than 1·4, passing through a sieve of 30-mesh and being caught on a 60-mesh sieve, and having an ash content of 30·0%; and (3) coal of density greater than 1·4 and passing through a 90-mesh sieve, and containing 15·3% of ash. Fraction 1 seemed to be a mixture of clarain and vitrain, fraction 2 seemed to be durain, whilst fraction 3 apparently consisted of a sort of cannel, known locally as "Jacks." Fraction 1 exhibited the phenomenon of attraction under the influence of an electric charge, whilst the particles of fraction 2 exhibited mutual repulsion. A partial separation of the two fractions from a mixture could be brought about by such means. The phenomenon seems to be connected with the tendency of the bright coal to adhere to a polished surface. Thus, when a mixture of fractions 1 and 2 was sprinkled over a glazed tile and the tile was tilted and tapped, the "adhering portion" contained 14·21% of ash, whilst the "scattered portion" contained 18·57%

of ash. Repulsion of the particles is dependent on their acquiring a like charge to that of the support or conductor, and if the particles be non-conducting, the acquirement of a charge depends on the presence of a surface film of moisture.—A. G.

Coal; Froth flotation tests on bituminous coking ——. O. C. Ralston and G. Yamada. Chem. and Met. Eng., 1922, **26**, 1081—1086.

Tests carried out on a coking coal from the Wilkeson mine (Wash., U.S.A.), No. 3 bed, showed that selective flotation could be successfully accomplished, the clean coal being first removed, followed by the "bone" portion, and finally by the ash. The fine coal will float to a certain extent without the addition of a frothing agent, and in any case this fine portion is most easily floated, very "thin" oils or soluble frothing agents giving the best results. If sufficient oil be added to float the larger sizes of coal, the fine concentrate tends to be dirty, since the fines, which are easily floated, consist of a mixture of fine coal and fine ash. It is therefore necessary to carry out a rough separation, the tailings and the concentrates from this process both being treated separately, and the tailings from this second flotation being rejected. In the cleaning of the concentrate portion, the middlings are retreated with the original feed, and the final middlings product consists almost entirely of "bone" coal which may find a market as a separate product. The "float-and-sink" method of analysis cannot be used for control of the process as regards the fine portion of the coal.—A. G.

Carbonisation [*of coal*]; *Increasing the rate of* ——. G. Weyman. Inst. Gas Eng., June, 1922. Gas J., 1922, **158**, 864—868.

In continuation of previous work (J., 1920, 168 T; 1921, 300 T), an investigation has been made of the relation between the properties of various coals and the rate of carbonisation, the experiments being conducted in a nickel-chrome-steel crucible holding 0·001 ton. The principal conclusions reached include the following: An increase in the rate of carbonisation caused by the alteration of chemical and physical conditions is accompanied by improvement in the calorific value of the gas, and of the thermal and volume yields per ton of coal. The rate of carbonisation can be very considerably increased by selection of suitable coals. When an increase in the rate of carbonisation is effected by increasing the carbonising temperature, for a certain time, the calorific value of the gas obtained at higher temperature is smaller than that of the gas obtained at lower temperature, but volume for volume, there is a slight balance in favour of the former. Volume for volume the calorific value of the gas obtained at higher temperatures falls off at a slightly greater rate than that of the gas obtained at lower temperatures.—J. S. G. T.

Coking processes; Chemistry of ——. *Production of bituminous substances of high melting point and their application to the production of metallurgical coke from non-caking coal.* F. Lierg. Z. angew. Chem., 1922, **35**, 264—268.

Coal tar pitch coked by itself gives hard, smooth coke. Non-coking coal ("sinter coal") requires 20%—30% of pitch admixed to make a good coke, but if the pitch be dissolved in tar oil, 7%—8% suffices. This coking effect observed in small-scale tests is not obtained in large-scale working owing to the long time required for coking and the low melting point of the pitch. The coking effect is best attained on the large scale by the use of bitumen of high melting point, say, 400° C. By extracting finely powdered coking coal with hot pyridine in a Soxhlet apparatus, and mixing the solution with water, a precipitate which dried to a dark-brown powder was obtained, amounting to 20·9% of the coal used. This substance did not melt when heated in carbon dioxide, but gave a swollen coke. The extraction residue had lost its coking properties, and re-addition of the extract to it did not restore them, but when the extract was dissolved in a solvent and added, the coking property was restored. A residue coking at 300° C. was made from coal-tar pitch by extracting with benzol and xylol. Further treatment with light coal tar oil gave a residue (pitch carbon) which was unaffected by heating to redness in a sealed tube, but gave off gas and coked when heated in a crucible, showing it to be a mixture of organic compounds of high molecular weight. The extracts of high melting point prepared as described above by means of pyridine still melted at the same temperature, after being mixed with an inert substance (soot), but showed reduced degrees of swelling. The pitch-carbon was somewhat soluble in hot pyridine, but the dissolved portion was mostly deposited again on cooling. Anthracene oil and heavier oils dissolved the pitch-carbon almost entirely and retained it in solution on cooling. The addition of such solutions enables a hard coke to be made from non-caking coals and even from lignite.—H. M.

Nitrogen; Liberation of —— *from coal and coke as ammonia.* A. C. Monkhouse and J. W. Cobb. Inst. of Gas Eng., June, 1922. Gas. J., 1922, **158**, 828—833. (*Cf.* J., 1921, 760 A.)

When a coke prepared at 500° C. is heated in hydrogen the proportion of nitrogen liberated uncombined is less than in an inert atmosphere. Hydrogen thus may both retard dissociation of ammonia and promote its formation from the coke. This coke, after being heated in hydrogen in stages to 1000° C., contained only 11·2% of the original nitrogen, while 68·2% had been recovered as ammonia. When heated in steam, the coke was completely gasified, the whole of the nitrogen being recovered as ammonia, and above 600° C. more rapidly than in hydrogen. A coke prepared at 1100° C. behaved similarly in steam, but the liberation of nitrogen was slower. Up to 1000° C. the cokes, heated in nitrogen evolved but little sulphur, though in hydrogen nearly all was set free as hydrogen sulphide. The coke prepared at 500° C. gave up 63·4% of its sulphur up to 800° C. and 93·8% up to 1000° C. No dissociation of hydrogen sulphide was observed. The liberation of sulphur by steam at 800° C., if not more rapid was more far-reaching than that by hydrogen at the same temperature. The effect of steam was evident from its action on the coke prepared at 1100° C., sulphur being liberated at 800° C., at which temperatures the nitrogen and carbon were but little attacked.
—H. J. H.

Carburetted water-gas plant with waste heat boiler; Thermal efficiency of a ——. Seventh Report of Research Sub-Committee of Gas Investigation Committee of Institution of Gas Engineers. Gas J., 1922, **158**, 800—823. (*Cf.* J., 1921, 649 A.)

The tests reported were made on two carburetted water-gas sets, installed at the Windsor Street Gas Works, Birmingham, each set having a rated daily capacity of 1,500,000 cub. ft. The sets were working under normal conditions for the production of a gas of calorific value 485 B.Th.U. per cub. ft., and three tests were made, two being over 5-day periods of continuous operation. The results obtained are detailed in 22 tables which include weight and thermal balances. The overall thermal efficiency of the plant, taking into account the steam raised from the "blow gases" by the boiler and that expended on auxiliary machines, averaged 68%. If the necessary steam had been independently generated with an efficiency of 70%, the efficiency would have been only 59·5%. The efficiency of the blue water-gas generator alone, without taking account of the steam required or raised, was only 53% (*cf.* the corresponding figure 56% of the Sixth Report, *loc. cit.*). The increased thermal efficiency of the carburetted water-gas process is due to the high efficiency of the oil-gas production, in these tests reaching 90%. The efficiency, therefore, increases with the amount of oil gasified per 1000 cub. ft.—in this case about 1·8 galls. The coke consumption was about 35·5 lb. per 1000 cub. ft. of carburetted water-gas. The waste-heat boiler generated about 64 lb. of steam per 1000 cub. ft. of carburetted water-gas, with a thermal efficiency of about 45%. Though this was sufficient to operate the plant, more might probably be obtained from the "blow" gases by modification in design. The intermittent operation of the plant involves difficulty in the sampling and measurement of temperature of the gases. A sampling device was constructed, and automatically operated by the valve gear, so that either "blow" or "run" gas could be separately collected over long periods. Special attention was given to the measurement of the temperature of "blow" gases entering the waste heat boiler and the elimination of errors due to lag in the pyrometers. The accumulation of silicious dust noted in the Sixth Report on a blue water-gas plant was not observed, presumably because the dust was removed in the tar.—H. J. H.

Gas meters; Life of ——. Report of Joint Committee of Institution of Gas Engineers and Society of British Gas Industries. Gas J., 1922, 158, 834—836. (*Cf.* J., 1921, 616 a.)

The changes in modern gas practice which have conduced to an increase in the corrosion of distributory systems are discussed. Substitution of oxide for lime purification has brought an increase in the content of carbon dioxide, hydrocyanic acid, and carbon bisulphide; these are all agents of corrosion in presence of moisture, and carbon bisulphide is active also in presence of ammonia. Higher carbonising temperatures cause an increased production of corrosive agents and destruction of the hydrocarbons which produce the protective oily film inside mains etc. This latter, however, can be restored by the use of carburetted water-gas. Deposition of water in mains favours corrosion and is best avoided by a preliminary over-compression, and, after separation of precipitated water, rarefaction to the normal distributing pressure. Increase in the proportion of oxygen in the gas has followed excessive "pull" on the retorts and additions of air at the purifier boxes. Sulphur dioxide is sometimes present in blue water-gas. Scrubbing the gas with solid chalk or washing with a cream of chalk (Taplay's process) is recommended to remove hydrocyanic acid as ammonium thiocyanate. To protect meters from corrosion, the vaporisation into the gas of petroleum oils has been practised. Some oils exert a solvent action on the grease of stuffing-boxes.—H. J. H.

Gas calorimeter; A recording and integrating ——. C. V. Boys. Inst. Gas. Eng., June, 1922. Gas J., 1922, 158, 882—887.

The author describes the construction and operation of a gas calorimeter designed more especially to meet the requirements of the Gas Regulation Act, 1920, in the matter of continuously recording the calorific value of town's gas, but immediately applicable to any gas. The calorimeter (see E.P. 180,080, page 569 a) is of the water-flow type, the water employed being continuously circulated through the apparatus and cooled to atmospheric temperature by a hot-air engine and cooling coil respectively. Water and gas are supplied at the correct respective rates, and the correction of the gas volume as affected by temperature, pressure, and humidity is also effected by a positive operation. The rate of water flow in the calorimeter is determined by the tipping, emptying, and draining at half-minute intervals of a celluloid bucket, the quantity of water discharged being adjusted so that if the gas is of the "declared" calorific value, the rise of temperature of the water in the calorimeter is exactly 10° C. The water supply likewise drives a small overshot celluloid water wheel which drives through an elastic connexion the escapement of a pendulum clock, and through an intervening mechanism—termed the "thinking" machine—the axle of the gas meter. The gas meter drum is of celluloid and is of such construction that the volume trapped is dependent only to a very slight degree upon the water level, which can be maintained nearly exactly constant. The meter drum rests loosely on a screwed axle. Correction of gas volume for temperature and pressure is effected by the intervention of the "thinking" machine consisting of a ball-disc-cylinder integrator, in which the position of the ball is determined by the volume of the air contained in a bell over mercury and water. Rotation of the ball is accompanied by rotation of the cylinder, resulting in endlong motion of the meter drum, whereby the gas inlet to the meter drum is closed or opened as required. The corrections effected are automatically recorded. The occurrence of accidents should the gas supply be temporarily cut off and resumed, or should the water supply cease, is prevented. The calorimeter proper comprises a lead heat interchanger and hot and cold water chambers. The burner is of silica and is surmounted by a silica dome. The operative thermometers are of brass and are sealed full of amyl alcohol. A lever system magnifies the nett deformation of the corrugated covers of the thermometers and the difference of temperature of the thermometers is recorded on a roll of paper kept in motion by a clock. Parallel lines are ruled on the paper to indicate definite percentage departures of the actual measured calorific value from the declared calorific value. An integrating device, operating after the manner of Amsler's planimeter, averages the departures of the calorific value of the gas from the declared calorific value since the indicator was last set.—J. S. G. T.

Paraffin hydrocarbons; Analysis of mixtures of hydrogen with the ——. J. G. King. Fuel, 1922, 1, 103—106.

The gases evolved in the low-temperature carbonisation of coal contain a large percentage of paraffins, varying considerably in composition and containing the higher members of the series. After determination of oxygen and carbon dioxide by absorption with caustic potash and alkaline pyrogallol solutions in the usual way, the gas is introduced into a special silica tube, containing copper oxide and heated to 280° C. The hydrogen and carbon monoxide are burnt to water and carbon dioxide respectively, and the gas is then returned to the main apparatus (that of Bone and Wheeler). The carbon dioxide is absorbed by caustic potash, and from this the percentage of carbon monoxide in the original gas can be calculated, whilst the paraffins are then exploded with excess air. The reductions in pressure after explosion, after absorption by potash, and after absorption by alkaline pyrogallol are noted. From the first of these two figures, the amount of hydrocarbons present can be calculated, and also the value for n in the expression C_nH_{2n+2} which gives the mean composition of the hydrocarbons present. From the third observation, the amount of oxygen used in the explosion can be calculated, and this should agree to within 0·3% of the amount theoretically required for the combustion of the hydrocarbons as determined from the first two observations. The silica tube may be heated by gas or may be wound with nichrome wire of 26 S.W.G., a consumption of 50 watts giving a temperature of about 300° C. This can be reduced to 280° C. by the inclusion of a suitable external resistance.—A. G.

Shale; Recent processes for treatment of oil ——. A. E. von Groeling. Petroleum, 1922, **18**, 487—493, 539—545.

After a critical review of the Scottish method of shale distillation and of other retort processes, the author describes the American "digesting process." The shale passes through a series of pulverisers and is mixed with a stream of preheated heavy oil, passes through a mixing cylinder, and into a still, or digester, where the shale undergoes the first part of the distillation in a series of four horizontal cylindrical or rectangular chambers, from the lowest of which it is transferred to the upper chambers *seriatim* by a screw mechanism. Thence it is transferred to a separate chamber to undergo the final distillation. The apparatus is directly fired, the combustion gases circulating contrary to the movement of the shale. The products of distillation are drawn upwards through the chambers and pass to a preheater for the digestion oil. The shale from the first operation is freed from oil by centrifuging before the final destructive distillation. Colorado shale gave a yield of 87 Amer. galls. of oil per ton, in place of 51 galls. in Scottish retorts. The oils obtained by first and final distillations are respectively of 0·807 and 0·798 sp. gr. and have a content of unsaturated hydrocarbons of 24%. No permanent gas is evolved. The temperature of the first stage is 650° F. (about 340° C.) and of the final stage 1500° F. (about 820° C.). Some kinds of shale have given a yield of 30% of paraffin wax from the oil. It is suggested that still better results would be obtained by the use of superheated steam. —H. M.

Gasoline; Production of —— *by cracking heavier oils.* E. W. Dean and W. A. Jacobs. U.S. Bureau of Mines, Tech. Paper 258, 1922. 56 pages.

Cracking was conducted under varying conditions. The apparatus consisted of a drip-feed lubricator delivering oil into the upper end of an electrically heated vertical iron tube, to the lower end of which was attached condensing and receiving apparatus. The tube contained a chain filling, a considerable length of the chain being packed under its own weight on a support arranged at the middle of the height of the tube. A thermocouple pyrometer measured the temperature of the tube wall midway of its height, and temperature was regulated by a rheostat. Experiments were made using Pennsylvanian distillate of gas oil type, Mid-Continental residuum fuel oil, Pennsylvanian kerosene distillate from which the fractions boiling below 175° C. had been removed, and a kerosene distillate from which constituents boiling below 200° C. had been removed. Increase in the rate of feed produced a decrease in the degree of cracking when the temperature was kept constant. Cracking seemed to occur mainly where the oil was in contact with the surface at which heat was supplied. Other conditions being constant, the yield of cracked products decreased as the temperature increased, the loss varying from 6% to 40%. The conditions which would produce commercial yields of gasoline were accompanied by losses of over 10%. The sp. gr. of the cracked product fell with increase in temperature up to 558° C., after which increase in temperature produced increased specific gravity of the product; at high temperatures the sp. gr. of the product may be greater than that of the raw material. With increased temperature the quantity of gasoline formed increased but the loss also increased. The sp. gr. of the recovered gasoline fraction was raised with increase of temperature, probably owing to formation of aromatic hydrocarbons. At pressures of 50 lb. and over the degree of unsaturation of the gasoline fraction decreased as the temperature increased, presumably owing to the formation of aromatic compounds. The ratio of gasoline formation to recovery loss, of importance in commercial working, is tabulated. Other conditions being constant the percentage of cracked oil recovered generally decreased as the pressure increased. At a temperature of 570° C. the sp. gr. reached a minimum value when using a pressure of 50 lb. per sq. inch. The percentage of gasoline formed generally increased with increase of pressure. The sp. gr. of the gasoline fraction generally increased as pressure increased, presumably owing to the formation of aromatic hydrocarbons. The degree of unsaturation of the gasoline fraction decreased as pressure increased. The pressure favourable to minimum ratio of gasoline formation to recovery loss varied between the limits 50 and 150 lb., depending upon the temperature. Increase in the rate of feed, which is equivalent to shortening the time of reaction, increased the percentage of cracked oil recovered. The sp. gr. of the recovered oil generally decreased with increased rate of feed. The effect of change of rate of feed on the quantity of gasoline formed was irregular. Increase in the rate of feed tended to decrease the sp. gr. of the gasoline fraction when the degree of cracking was considerable. The degree of unsaturation of the gasoline tended to increase with increased rate of feed. Gasoline can be produced more economically at high furnace temperatures and at a high rate of feed than by using lower temperatures and rates. A much larger amount of carbon was formed when using a residual oil as raw material than with a distillate. A series of graphs show the difference in behaviour between Mid-Continental residual and paraffin base distillate. Comparing kerosene with gas oil as a raw material for cracking, with the kerosene the recovery was greater, the yield of gasoline less, its sp. gr. lower and degree of unsaturation less. Kerosene and gas oil are about equally suitable for cracking, the gas oil being slightly easier to transform, but giving rather heavier losses in recovery. Naphthene base oils required a higher temperature for cracking than paraffin base oils. It is not economical to crack oil containing naphtha fractions. It would be more economical to separate the naphtha in a topping plant, and treat the residue in a cracking plant, the naphtha being added to the cracked product, as by this method a greater yield of gasoline would be obtained. The residuum obtained after the removal of gasoline from a cracked product, when recracked, yields less favourable results as regards cracked oil recovery and percentage of gasoline production than a fresh oil, and yields a larger deposit of carbon. The volume of gas formed is closely related to the loss of oil during cracking.—H. M.

Paraffin wax; Effect of —— *on viscosity of petroleum oils.* E. W. Dean and M. B. Cooke. J. Ind. Eng. Chem., 1922, **14**, 410—411.

Commercial paraffin wax was added to samples of water-white kerosene, transformer oil, spindle oil, medium "auto oil," "Liberty aero oil," and distillates prepared from crude oil in the laboratory. All these products had been prepared from Pennsylvanian oils. The addition of wax to kerosene increased its viscosity. The effect on the distillates was negligible, while the other oils suffered a decrease in viscosity. The removal of wax from the distillates produced no appreciable change in their viscosities. The wax could be separated into constituents of different physical properties by dissolving in benzene and cooling. When dissolved in oil, paraffin wax behaved like an oil of low viscosity at temperatures below its melting point.—H. M.

Petroleum oils; Iodine values of ——. S. Kawai. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 406—419.

The author has studied the influence of concentration, temperature, and time of absorption on the iodine value of some petroleum oils, using three iodine solutions, viz., those of Wijs, Hübl, and Hanus. The iodine value decreases with increase in the concentration, and increases with increase of temperature and time of absorption. The three different solutions, Wijs, Hanus, and Hübl, give iodine values in descending order.—K. K.

Transformer and turbine oils; Determination of sludge values of ——. F. Schwarz and J. Marcusson. Petroleum, 1922, **18**, 741—742.

50 g. of oil is heated to 120° C. for 50 hrs. in a 200 c.c. Erlenmeyer flask. The oil is then heated for 15 mins. to 80° C. under a dephlegmator with a mixture of 50 c.c. each of 50% (by weight) alcohol and a 4% solution of caustic soda, and afterwards strongly agitated for 5 min. The mixture is then allowed to stand over-night in a separating funnel. As much as possible of the mixture is filtered into a measuring cylinder and extracted with 30 c.c. of light petroleum spirit. The resulting extract is treated with 10 c.c. of 50% alcohol with the addition of a few drops of caustic soda. The alcoholic layer is mixed with the tar soap solution, and acidified with dilute hydrochloric acid. After shaking up two or three times successively with 50 c.c. of benzene, the benzene extract is washed with distilled water till free from mineral acid, evaporated, and dried at 105° C. The amount of tarry matter obtained from the amount of fluid mixture taken gives, by calculation, the proportionate amount for the oil taken.—H. M.

Iodine value. Holde and others. *See* XII.

Patents.

Fuel [*coal*]*; Method of burning* —— *in furnaces.* W. H. Nield and W. Melland. E.P. 180,401, 16.2.21.

Coal is caused to travel along a horizontal tube in the upper part of the furnace, so that it becomes coked on its passage, and the coke falls from the open end of the retort-tube on to grate bars and is burnt. The coal gas etc. is drawn out by a fan backwards from the retort and passed through condensers where by-products are collected, and the residual gas is burnt in the furnace at a point below the retort but above the fire-bars.—B. M. V.

Gas-heated ovens and retorts. Stettiner Chamotte-Fabr. A.-G. vorm. Didier. E.P. 174,039, 4.11.21. Conv., 12.1.21.

In an installation comprising a number of oven units heated independently, each unit is provided with an auxiliary gas producer which is not used for normal working, but, as a rule, serves only for heating the unit up to working temperature. Normally, a main gas producer serves to supply the necessary heat for working all the units. The auxiliary producers can be cut off from their respective oven units, and communicate with each other by means of conduits provided with valves. Above the auxiliary producer, which is directly connected with the oven, there is a recuperator which is heated by the waste gases from the oven and through which the gas from the main gas producer passes.
—A. R. M.

Retort for gas-producing apparatus. S. F. Sworski and F. F. Ratajezak. U.S.P. 1,418,745, 6.6.22. Appl., 18.7.21.

A gas-generating receptacle, the walls of which at the bottom and lower part are thicker than at the upper part, is suspended in the upper part of a furnace. A bucket fits snugly into the lower part of the receptacle.—A. R. M.

Chamber oven for the manufacture of gas and coke. H. Koppers. G.P. 350,483, 3.6.14.

In chamber ovens utilising rich gas and low-grade gas, it is the practice to dilute the rich gas with flue gas to the same calorific value as the low-grade gas. On the other hand, in plants using the rich gas alone, the regenerator is combined with collecting mains running on either side of the battery which serve as reversal mains, conveying alternately air for combustion and flue gases. By the invention it will be possible in an installation of the latter type to heat one part with rich gas diluted with flue gas, and another part with low-grade gas. The collecting reversing mains serve as flue gas mains and as conduits for air diluted with flue gas, and are combined with connecting pieces which have connexions with these mains, with the conduit for low-grade gas and with the open air, and can be closed as desired.—A. G.

Furnace for the continuous production of gas and coke. E. Riepe. G.P. 350,509, 31.5.21.

The furnace contains two vertical retorts which are connected at their lower open ends by a square main, through which the coke is discharged. If it is desired to produce a specially good gas, lignite and coal may be carbonised simultaneously in the two retorts. The upper end of the retort filled with lignite is closed and the gases from the lignite are withdrawn and passed through the charge of coal, acting as an internal heating medium. The poor gas reacts with the coal yielding a richer gas which is mixed with the gas evolved by carbonisation of the coal.—A. G.

[*Oil*] *gas; Process and apparatus for making* ——. General Oil Gas Corp., Assees. of W. C. Dayton. E.P. 167,736, 19.1.21. Conv., 9.8.20.

Gas of constant composition and of a calorific value of 200—600 B.Th.U. per cub. ft. or over, is made by mixing a hydrocarbon oil with a stream of preheated air, heating the mixture by means of heat interchange with hot gas leaving the generator, and passing the heated mixture into a gasifying chamber which is maintained at a temperature of 1350°—1750° F. (730°—955° C.). Heat is supplied by combustion of the oil with a quantity of air insufficient for complete combustion. In ordinary working, external heat is not applied, but a pilot burner is provided for heating the chamber when it is desired to make rich gas, or when the apparatus is first put in operation.—A. R. M.

Gas making; Using heavy oil in ——. O. B. Evans and H. G. Terziam, Assrs. to The United Gas Improvement Co. U.S.P. 1,418,782, 6.6.22. Appl., 2.7.20.

Gas oil is gasified by introducing it into a chamber containing preheated checkerbrick. A deposit of carbon is formed on the checkerbrick and is removed by blowing with preheated air.—T. A. S.

Constant heat value; Apparatus for maintaining [*gas at a*] ——. H. F. Smith, Assr. to The Gas Research Co. U.S.P. 1,417,635, 30.5.22. Appl., 11.3.18.

A portion of the gas which is to be maintained at a constant calorific value by dilution is burnt (after dilution) at a constant rate, and the heat produced is utilised to regulate an electrical device which in turn regulates a valve for a fluid under pressure. The latter operates the valve through which the diluent is supplied.—B. M. V.

[*Gas producers;*] ***Method of preventing wall action** [in ——].* H. F. Smith, Assr. to The Gas Research Co. U.S.P. 1,417,636, 30.5.22. Appl., 24.5.18.

In addition to the active fluid (air or steam) which is blown into a gas producer so as to pass mainly up the central zone, a comparatively inert fluid is passed up through the fuel near the walls. —B. M. V.

[*Gas producers;*] *Method of fuel agitation [in ——].* H. F. Smith, Assr. to The Gas Research Co. U.S.P. 1,417,637, 30.5.22. Appl., 1.8.18.

An explosion is caused in a vessel outside the producer, and the high-pressure gases thus produced are admitted to the under side of the ash zone of the fuel.—B. M. V.

Ammonium chloride; Method of producing —— from coal or shales. O. L. Christenson and B. A. Hedman; Hedman, Assee. of K. I. M. Gisiko. E.P. 169,948, 25.2.21. Conv., 6.10.20. Addn. to 159,817 (*cf.* U.S.P. 1,397,264; J., 1922, 4 A).

In the method for recovery of ammonium chloride by impregnating coal or shale before distillation with an alkali chloride, silica, and water, free hydrochloric acid is added as well. The proportions may be 3·2 pts. of 30% hydrochloric acid, 2·5 pts. of silica, and 4 pts. of common salt to 100 pts. of coal. The acid combines with ammonia liberated at temperatures below the decomposition temperature of the salt.—C. I.

Acetylene; Storage receptacles for ——. W. J. Mellersh-Jackson. From Air Reduction Co. E.P. 180,273, 24.1.22.

A tank or cylinder contains a solvent for the acetylene, disseminated through a body of finely-divided wood of the ochroma family, *e.g.*, *Ochroma lagopus* (balsa). The wood, which is of a light, porous, and elastic nature, is introduced into the containing vessel and compressed therein. If desired, a binder or inert porous matter may be added to the wood filling.—A. R. M.

Hydrocarbons; Cracking ——. The Kansas City Gasoline Co., Assees. of H. M. Lasher. E.P. 160,161, 22.2.21. Conv., 12.3.20.

High-boiling hydrocarbons are mixed with a relatively small quantity of carboniferous material, *e.g.*, bituminous coal, and heated with agitation in a still or retort. Arrangements are made for passing forward light distillate and the return of heavy distillate for further cracking. Fresh high-boiling hydrocarbon is added to the carboniferous material to replace that distilled off. The distillation is carried on at atmospheric pressure out of contact with the air. In an example given the cracking temperature was 600°—1000° F. (about 315°—540° C.).—T. A. S.

Petroleum oils; Process and apparatus for the distillation and cracking of ——. S. L. Gartlan and A. E. Gooderham. E.P. 179,644—5, 8.2.21.

A mixture of steam and petroleum oil is fed into a retort, and the vapours are drawn off by a compressor and condensed under pressure, which is varied according to the final product desired. The retort is heated by a step-by-step process, the liquid volatile at each temperature being drawn off at that temperature and the pressure in the retort being maintained at about that of the atmosphere. As the temperature of distillation rises, steam superheated to that temperature is admitted to the retort. It is stated that 75% of the petroleum oil can be converted into low-boiling naphtha. —T. A. S.

Petroleum; Method of refining ——. Refining oil. P. T. Sharples. U.S.P. 1,416,890—1, 23.5.22. Appl., (A) 12.3.20, (B) 6.4.22.

(A) The residue, obtained after distilling off gas, naphtha, and burning oils from crude petroleum with the avoidance of substantial cracking, is chilled to precipitate the wax. The chilled residue is submitted to centrifugal treatment under such conditions that the wax and residue free from wax are continuously discharged. (B) The residue, obtained by the removal of the lower-boiling constituents from crude petroleum without substantial cracking, is treated to cause the precipitation of the wax whilst maintaining the fluidity of the oil, so that they may be separated by centrifugal force; the wax and oil free from wax are discharged continuously.—T. A. S.

Mineral oil and carbohydrogen [hydrocarbon] gas extracting process. G. Schneiders, Assr. to A.-G. "Eos." U.S.P. 1,418,097—8, 30.5.22. Appl., (A) 2.9.19, (B) 15.8.21.

(A) A passage driven into a bituminous deposit is protected by means of an air-dam which prevents the leakage of gas and oil into the passage. The gas and oil are removed from the deposit by means arranged in the passage. The air-dam is moved along into the deposit as gas and oil are removed. (B) Oil-bearing sand is removed from a deposit and simultaneously subjected to separating treatment. The process consists in dislodging the sand by a jet of fluid so that by the action of the jet and friction of the grains the adherent bitumen is removed. —T. A. S.

Petroleum vapour; Apparatus for treating ——. D. W. Hoge, Assr. to Izash Oil and Refining Co. U.S.P. 1,418,375, 6.6.22. Appl., 14.6.17.

Petroleum vapour is converted into gasoline by passing it through a continuous conduit built up of straight sections and heated in a bath of molten metal. The conduit system is bodily removable from the bath.—T. A. S.

Cracking oils; Process of and apparatus for ——. G. L. Hoxie. U.S.P. 1,418,713, 6.6.22. Appl., 9.8.18.

The process consists in heating a small portion of the oil to cracking temperature and immediately mixing it with a large volume of oil at a substantially lower temperature, the low-boiling products being distilled off from the large volume of oil. Several forms of apparatus are proposed for working the process.—T. A. S.

Emulsion; Process of making ——. Process of making waterproof composition. Coloured bituminous compositions and process of making same. Waterproof product. Process of treating saturated fibrous compositions. Process of saturating felt. L. Kirschbraun. U.S.P. 1,417,835 and 1,417,837—41, 30.5.22. Appl., (A) (D) 1.2.19, (B) 15.7.20, (C) 16.3.18, (E) 10.9.19, (F) 21.11.19. Renewed (C, D, E) 28.10.21, (F) 7.11.21.

(A) A bulk supply of emulsion is formed by making a mixture of water and colloidal clay, adding a waterproof adhesive binder, and thoroughly mixing into an emulsion in which the binder forms the internal phase and the water and emulsifying agent the external phase. Further quantities of water and colloidal clay and of binder are separately fed into the bulk supply, the latter being agitated whilst forming the emulsion. (B) A stock is made consisting of bitumen in a discrete form in an aqueous vehicle and containing an oxidising agent.

(c) A bituminous product consists essentially of solid residue remaining after steam distillation of wax tailings. The product is yellowish brown and pitchy, and has a conchoidal fracture when cold. (D) Mottled waterproof sheet is prepared by making a coloured, emulsified, bituminous matrix and mixing this with a fibre of different colour from the matrix. The mixture is formed into a sheet so that an uneven surface distribution of the binder is caused, thus producing a mottled appearance. (E) The fibrous and bituminous constituents of waste saturated felt are recovered for re-use by mechanically disintegrating the fibres with their contained bitumen in the presence of a heated emulsifying agent. (F) A hot bituminous liquid is applied to one face of hot dry felt, at or adjacent to the point where it is being wound up.—T. A. S.

Petroleum oil sludges; Separation of ——. S. H. Diggs, Assr. to Standard Oil Co. U.S.P. 1,418,781, 6.6.22. Appl., 23.12.18.

The acid sludge obtained in the treatment of petroleum oils with sulphuric acid is mixed with sludge obtained by treating oils with fuming acid and with gas oil. The whole is mixed with water and steamed, when separation of the acid takes place. The operations are repeated until practically all the acid is removed. The residues are suitable for the manufacture of commercial asphalt. —T. A. S.

Gas generator. S. Moore. U.S.P. 1,418,158, 30.5.22. Appl., 7.12.21.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Burners; Some gas —— *and a moral.* C. Carpenter. Inst. Gas Eng., June, 1922. Gas J., 1922, **158**, 853—861.

The development of modern gas lighting burners is briefly reviewed, and it is pointed out that conditions governing the manufacture of these appliances are nowadays such as to facilitate the manufacture and use of shoddy burners—faulty in construction and inefficient in use. Curves are given comparing the lighting efficiencies of samples of such burners with that of the "Metro" burner introduced by the author. Thus, while the lighting efficiency of the "Metro" burner is 3930 mean radial candle-hours per therm, the efficiencies of various shoddy burners range from 920 to 2940 mean radial candle-hours per therm. A plea is urged that gas supply undertakings should formulate certain standards to which gas fittings, burners, glassware, mantles, etc., should conform. Reference is made to certain scientific principles concerning gas burner design, more especially to the deposition of dust upon the injector orifices, and to the phenomena of air-entrainment by the issuing jet as conditioned by the size and disposition of the orifices. The orifice dimensions, and their disposition in the case of multiple-hole injectors, may be such as to produce inherent instability and unsteadiness of the flame of the burner.—J. S. G. T.

Methane; Purification of gases [for incandescence lamps] from ——. G. R. Fouda and H. N. van Aernem. J. Ind. Eng. Chem., 1922, 14, 539—540.

In the usual method for the removal of methane from nitrogen or argon for gas-filled lamps, by the action of heated copper oxide, an inconveniently high temperature is necessary. The decomposition of methane, $CH_4=C+2H_2$, with a nickel catalyst, for which Mayer and Altmayer (Ber., 1907, **40**, 2134) have determined the equilibrium constant, is facilitated by a low partial pressure of methane, and is therefore suitable. Investigations with a mixture of nitrogen with about 2% of methane have substantially confirmed Mayer and Altmayer's figure. A series of equilibrium curves for different temperatures is given, showing for example that at 500° C. this treatment reduced the methane content of a gas from 1·5% to 0·24%. The gas must afterwards be passed over copper oxide to remove the hydrogen liberated.—C. I.

Patents.

Retorts for the distillation of oil-bearing shales or other like materials. J. S. Black. E.P. 179,964, 29.7.21.

The contents of the vertical retort are supported on a platform, above which is a member which oscillates angularly so as to break up and discharge the spent shale. The products of distillation are drawn off at various heights from the sides of the retort, with a view of effecting a separation of the distillates.—T. A. S.

Peat and like substances; Method of distilling and gasifying —— [and production of cement]. A. A. F. M. Seigle. E.P. 180,081, 24.2.21.

Agglomerates are prepared by mixing peat or the like with calcium carbonate, calcium chloride, and silicious matter or cement, and are hardened by treatment with saturated steam under pressure in a digester so as to cause formation of calcium hydrosilicate. The agglomerates are distilled at a comparatively low temperature, say 550°—580° C., in order to obtain condensable hydrocarbons, ammonia, methyl alcohol, aliphatic compounds, etc., and afterwards heated to a higher temperature, whereby complete gasification of the fixed carbon is effected with the formation of, mainly, carbon monoxide and other permanent gases. A residue of hydraulic lime is obtained by heating to a temperature of 1100°—1200° C., while if the temperature is raised to 1500° C. the residue consists of hydraulic cement.—A. R. M.

Retorts for destructive distillation; Vertical ——. E. Burnet. E.P. 180,161, 13.4.21.

Vertical retorts of narrow rectangular cross-section, particularly adapted for the distillation of shale, are provided at various heights in their side walls with horizontal slots of such dimensions and having their lower surfaces so inclined that the column of descending material can spread out at these positions without coming to rest. Distillation products are withdrawn through these openings and hence do not have to pass through the whole column of material in the retort. The retorts may be made with special sections formed as described above, interposed between the sections of the usual shape, and the heating flues are also divided into sections so that the temperature of the special sections of the retort can be maintained at a temperature independent of that of the ordinary sections.
—A. R. M.

Carbonisation; Apparatus for —— with endless belt for the material to be carbonised and internal heating. F. Caspari. G.P. 351,279, 31.12.20.

The gas offtake is situated immediately below the trough of the perforated endless belt, which is loaded with the raw material. The gases evolved are therefore immediately removed from the hot zone of the furnace and are not subjected to overheating. Decomposition of the tar is also prevented.—A. G.

Charcoal; Vegetable ——. Wilson Bros. Bobbin Co., Ltd., and S. C. Bone. E.P. 180,611, 22.10.21.

Vegetable charcoal which is free from liability to spontaneous ignition, is prepared by passing ordinary vegetable charcoal, preferably direct from the retort in which it has been made, through chambers containing an inert gas, preferably a gas containing free nitrogen, whereby the charcoal becomes impregnated with the gas.—A. R. M.

Thermionic cathodes [for vacuum tubes] and method of making the same. Western Electric Co., Ltd. From Western Electric Co., Inc. E.P. 180,090, 28.2.21.

An electron-emitting cathode consists of a core, formed of an alloy of Pt 95% and Ni 5%, coated with a thermionically active material. The latter is prepared by coating the core with alkaline-earth carbonate, *e.g.*, barium or strontium carbonate, and heating for 5—20 mins. in an atmosphere of oxygen at 1200° C., and subsequently *in vacuo* or in a non-oxidising atmosphere for several minutes at 1000° C. Palladium, osmium, rhodium, iridium, or ruthenium may replace the platinum in the core, and the nickel may be replaced by cobalt.
—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Coal tar; Stoppage of condenser in distillation of ——. W. Spalteholz. Chem.-Zeit., 1922, **46**, 544.

In distilling a tar with a high content of water, after driving off the water, light oil, and part of the creosote oil and naphthalene, crust-like formations were noticed at the condenser outlet, and the flow of oil almost ceased. There followed an explosive ejection of oil mixed with crystalline masses of ammonium chloride, which was formed to the amount of about 5—10 kg. per 15,000 kg. of tar. The large quantity of ammonium chloride is attributed to the use of coal which had been in contact with sea water during transport.—H. M.

Benzene, toluene, and m-xylene; Distillation of a mixture of ——. L. Gay. Chim. et Ind., 1922, **7**, 851—854.

The distillation takes place in two successive dephlegmating columns. The process may be conducted so as (1) to separate practically pure *m*-xylene at the base of the first column, and to separate the mixed benzene and toluene in the second column, or (2) to extract benzene from the top of the first column, and to separate the liquid mixture of toluene and *m*-xylene by further distillation. A series of triangular graphs show the rate of exchange of heat units, and under what circumstances the first, and when the second process is preferable. If the triangular diagram be divided into two portions by a line extending from the toluene corner to a point on the benzene-*m*-xylene side corresponding to 72% of benzene, for liquid mixtures, or by a line extending from a point on the benzene-toluene side corresponding to 85% of benzene to a point on the benzene-*m*-xylene side corresponding to 51% of benzene, for gaseous mixtures, then those mixtures falling in the lower portion of the triangle are best separated by method (1) and those falling in the upper portion by method (2).
—H. M.

Tetralin (tetrahydronaphthalene) and dekalin (decahydronaphthalene); Physico-chemical investigation of ——. W. Herz and P. Schuftan. Z. physik. Chem., 1922, **101**, 269—285.

Tetralin and dekalin are useful solvents, and have possibilities as combustibles and sources of power, and are also of value for lubrication. They have the following physical constants—b.p., 207·3° C. and 191·7° C.; heat of vaporisation, 79·32 cals./g., 71·01 cals./g.; m.p., $-35·0° \pm 0·5°$ C., $-124° \pm 2°$ C.; sp. gr. at temperature *t*, $0·9843(1-763\times10^{-6}t)$, $0·8975(1-818\times10^{-6}t)$; surface tension at the boiling point, 17·46 dynes/cm., 15·71 dynes/cm. respectively. (*Cf.* J.C.S., July.)—J. F. S.

Patents.

Distillation of liquids, such, for example, as tar and oils. J. L. Wilson. E.P. 180,347, 17.11.20.

The oil is distilled in a continuous still, inert gas being passed through the distilling liquid. Separation of the distillates is effected by fractional condensation. Heat is conserved by using the condensers and the coolers for the still residue as preheaters for the incoming oil. The arrangement of the still-head prevents the return of any condensed liquid to the still. Vapours from the preheaters and those not condensed by condensers in the preheaters are passed through water-cooled condensers.
—T. A. S.

Condenser for vacuum distillation of petroleum, tar, etc. L. Steinschneider. G.P. 351,004, 6.3.20. Conv., 13.8.18.

Between each outlet tube and the common main, serving as conduit for all vapours from the distillation units to the condenser, there is a catch-tube, provided with a waste pipe. If the contents of a still froth over they pass through the catch-tube and the waste pipe to a catch pot situated underneath, and cannot pass through the common main to the condenser. The operation of the other stills is thus not interfered with. Entrained oil can be separated from the vapour in the catch-tubes by means of baffles, and can be recovered, whilst the vapour passes on to the central condenser.—A. G.

Hydrocarbons; Processes for refining ——. J. Demant. E.P. 179,610, 4.2.21.

The acid treatment of hydrocarbons for the removal of impurities is varied so that instead of the foreign matters being lost in solution in concentrated acid they are polymerised and recovered as high-boiling oils from the hydrocarbons by subsequent distillation. To this end the hydrocarbon is treated with relatively dilute acid at suitable temperatures. The action is catalytic; the acid is unchanged, and may be used repeatedly. By treating 90% benzol with 10% of its weight of sulphuric acid of 46° B. (sp. gr. 1·468) at about 65°—70° C. for 5—6 hrs., and subsequent treatment with soda and distillation, pure benzol is recovered, and on distilling the residue with steam, oil and a varnish-like material are obtained. In the case of coal tar naphtha treatment with acid of 46°—48° B. (sp. gr. 1·468—1·498) at 110° C. for 5—6 hrs. converts the indene and coumarone into a viscous oil of high value, having a freezing point of −10° to −15° C.—T. A. S.

Naphthalene and other volatile solid organic bodies; Purification of ——. C. E. Andrews, C. Conover, K. B. John, and C. E. Ruth. E.P. 179,991, 19.1.21.

Crude naphthalene, or other volatile solid organic material, is heated to its melting point, *e.g.*, about 110°—120° C., in a vessel provided with coils through which hot oil is circulated. Heavy impurities in the naphthalene sink into a space below the coils, while an outlet pipe attached to the end of the vessel at a point above the bottom conveys the liquid material to the middle of a series of three vaporisers arranged in steps. Each vaporiser is heated by coils containing hot oil, the lowest of the series to 140°—150° C., the middle one to 120°—130° C., and the uppermost to 110°—120° C. Vapour from the middle vessel passes into the uppermost vessel, in which a portion condenses and returns as liquid to the middle vessel, while the remainder passes to a series of condensing chambers. Liquid from the middle vessel flows into the lowest vessel, whence the vapour returns to the middle vessel, and the residual liquid is withdrawn. Air or other gas is blown through the liquid in the bottom vessel, and each vessel is provided with baffles alternately attached to and clear of the lid. A quantity of sodium hydroxide or the like, amounting to 0·5 to 5% of the weight of the naphthalene charged into the apparatus, is added, *e.g.*, as a 5% aqueous solution, to one or more of the vaporisers.—L. A. C.

Lubricating oils; Process for the production of —— of high viscosity from coal tar oils. Chem. Fabr. Worms A.-G. G.P. 350,801, 13.9.17.

The oils are treated at ordinary, or higher, temperatures with an acid condensing agent other than sulphuric or waste acid. Suitable condensing agents are sulphuryl and thionyl chlorides, phosphorus chlorides, phosphorus oxychloride, aluminium chloride, phosphorus pentoxide, and sulphur dichloride. Anthracene oil, with a flash-point of 140° C. and a viscosity of 4·6° Engler at 40° C., gives, on treatment with sulphuryl chloride and removal of the hydrochloric acid produced, a lubricating oil with a flash-point of 172° C. and a viscosity of 40° Engler at 40° C.—A. G.

Lubricating oil substitute. G. Schultz. G.P. 351,201, 15.5.17.

The residue from the preparation of anthracene from anthracene oil, which is rich in phenanthrene, is dissolved in petroleum or solvent naphtha and is treated with sodium. Alcohol is then added gradually until all the sodium has been combined, the liquid is diluted with water, the aqueous solution separated, and the oil distilled. The lubricating oil is produced from the fraction boiling above 300° C. Instead of nascent hydrogen (sodium and alcohol) molecular hydrogen may be used in the presence of a catalyst.—A. G.

[Tar] distillation process and product thereof. J. M. Weiss, Assr. to The Barrett Co. U.S.P. 1,418,893, 6.6.22. Appl., 7.2.20.

See E.P. 158,852 of 1920; J., 1921, 575 a.

IV.—COLOURING MATTERS AND DYES.

Electrochemical study of the reversible reduction of organic compounds. J. B. Conant, H. M. Kahn, L. F. Fieser, and S. S. Kurtz, jun. J. Amer. Chem. Soc., 1922, **44**, 1382—1396.

The reduction-oxidation potentials of six anthraquinonesulphonic acids have been measured by a titration method, using titanous chloride and sodium hydrosulphite, and the results obtained over a wide range of hydrogen-ion concentration have been found to be in accord with a general equation established for expressing the reduction-oxidation potentials of compounds of the type of quinone, *e.g.*, vat dyestuffs, in both acid and alkaline solutions. The validity of the method is shown by determinations of the potentials of mixtures of the reduced and oxidised compounds.—W. G.

Patent.

Mordant dyeing dyestuffs and chromium compounds thereof; Manufacture of ——. O. Imray. From Soc. of Chem. Ind. in Basle. E.P. 180,433, 22.2.21.

See U.S.P. 1,402,350 of 1922; J., 1922, 137 a.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Effect of fireproofing solutions on ——. G. Durst. Textilber., 1922, **3**, 228—229.

The work of Sibley (J., 1921, 806 a) is adversely criticised, mainly on the ground that the tests were not carried out under conditions which would apply to the large-scale fireproofing of cotton fabrics.—A. J. H.

Silk-fibroin; Composition of —— and its structure. E. Abderhalden. Z. physiol. Chem., 1922, **120**, 207—213.

100 g. of silk-fibroin (free from ash) yielded 25 g. of *d*-alanine, 2·5 g. of *l*-leucine, 1·5 g. of phenylalanine, 1·8 g. of *l*-serine, and 1 g. of *l*-proline. Altogether 86·4% of the amino-acids were accounted for. The examination of the products of hydrolysis in the intermediate stages of hydrolysis showed the presence of considerable quantities of *d*-alanylglycine-anhydride, m.p 240°—247° C., $[\alpha]_D = -5{\cdot}02°$, small quantities of glycyl-*l*-tyrosine-anhydride, and a compound containing serine, *d*-alanine, and glycine.—S. S. Z.

Wood and other raw materials; Determination of cellulose in —— by the action of chlorine dissolved in carbon tetrachloride. E. Heuser and H. Casseus. Papierfabr., 1922, **20**, Fest- u. Auslandsheft, 80—93.

The determination of cellulose in wood by Cross and Bevan's chlorination method is simplified and brought more under control by treating the ground material with a solution of chlorine in carbon tetrachloride. A solution saturated by passing chlorine gas through carbon tetrachloride at the ordinary temperature contained 8·10 g. of chlorine per 100 g. of solvent and was practically stable for several weeks. The wood should be ground to a meal of medium fineness; too coarse particles are attacked unevenly and too fine particles present some difficulty in the subsequent filtrations. It is not necessary to remove the fat and resin by preliminary extraction. The chlorination proceeds too slowly if the wood is treated in the dry state and the best procedure, in the case of wood meal of medium fineness, is to moisten the material in a Gooch crucible and allow it to drain without suction before proceeding to the first chlorination. For the second and third chlorinations the quantity of moisture must be greatly reduced and a current of air is sucked through the cake of material in the Gooch crucible for a considerable time. A special apparatus used by the authors for the treatment of the wood with chlorine consists of a short wide cylindrical shaking-funnel fitted with a ground stopper and a tap at the lower end. The lower part of this funnel is ground to fit into the upper part of the Gooch crucible, which is detached for the shaking treatment and attached for the filtration and extraction treatments. About 1·5 g. of wood meal is treated in the funnel with 50 g. of the chlorine solution, the stopper is tied down, and the mixture is shaken in a shaking machine. With the right degrees of moisture, the times of chlorination may be reduced to 30 mins. for the first, 20 mins. for the second, and 15 for the third. After each treatment the funnel is fitted to the Gooch crucible, the tap is opened, and the contents are transferred to the filter chamber. The carbon tetrachloride is filtered off and the cake is washed first with alcohol and then with water. Treatment with hot 2% sodium sulphite solution in the Gooch crucible then follows, and the purified residue is transferred again to the funnel for the next chlorination. The consumption of chlorine may be determined by shaking the carbon tetrachloride filtrate with potassium iodide solution and titrating; a train of gas-washing vessels containing potassium iodide should be inserted between the filter flask and the pump. The results are extremely concordant, showing 59·7% of cellulose, containing pentosan, in wood meal; the cellulose is free from lignin and the absence of destructive oxidation is shown by the low "copper value" of the final product, *i.e.*, 0·8—0·9, as compared with 3·2 for the cellulose prepared by the chlorine gas method.—J. F. B.

Sulphite pulps; Determination of the chlorine consumption value of ——. R. Sieber. Zellstoff u. Papier, 1921, **1**, 181—184. Pulp and Paper Mag., 1922, **20**, 425—427. (*Cf.* J., 1921, 382 A; 1922, 409 A.)

The results of the test originally described are greatly influenced by the degree of alkalinity of the bleach liquor and the temperature at which it acts. The prescription, therefore, is modified by specifying an alkalinity equivalent to 10 c.c. of $N/10$ caustic soda in the quantity of bleach liquor taken, and a standard temperature of 20° C. The quantity of active chlorine taken for 5 g. of dry pulp is 0·3 g. and the necessary conditions are best established by mixing calculated quantities of two bleaching powder solutions of different known strengths and alkalinities. The following formula is useful for calculating the necessary quantities of the two solutions: $x=(422w-220q)/(wp-vq)$ and $y=(250p-422w)/(wp-vq)$, in which p and q are c.c. of $N/10$ As_2O_3, required for 5 c.c. of the stronger and weaker solutions respectively, and v and w are c.c. of $N/10$ acid equivalent to 25 c.c. of the respective solutions. Then $x+y$ c.c. of the mixed solutions contains 0·3 g. of active chlorine and an alkalinity equivalent to 10 c.c. of $N/10$ caustic soda. One solution is made up with 30 g. of bleaching powder per litre and the other with 80—90 g. Both are filtered and preserved in brown glass bottles under a layer of paraffin oil. The two solutions are standardised every time before mixing, and sufficient of the mixed solution may be prepared to last a week; this is also kept in a brown bottle under paraffin, the bottle being connected with the burette for the test.—J. F. B.

Artificial silk industry; Progress in the ——. E. Bronnert. J. Soc. Dyers and Col., 1922, **38**, 153—162.

In the manufacture of collodion silks the recovery of the organic solvent is one of the major economic problems. When spinning into aqueous baths, the author succeeded in eliminating the use of ether by dissolving the dinitrocellulose in a mixture of alcohol and calcium chloride. Cuprammonium solutions of cellulose are obtained economically in a sufficiently concentrated form by suitable pre-treatment of the cellulose and the judicious use of low temperatures. Fine silk of good quality is obtained by spinning with dilute acid, but the caustic soda coagulating baths are more generally employed and are moreover essential for spinning thick filaments (horsehair). Temperatures up to 60°—70° C. are employed. The addition of sugar to the caustic soda bath is necessary in order to preserve the lustre; the sugar prevents the formation of coarse precipitates of cupric hydroxide in the thread and holds it in the form of a clear solid solution. The recovery of the copper and ammonia from the spent baths presents no serious difficulty. The resistance to water of cuprammonium silk is stated to be superior to that of other artificial silks, and this is one of the reasons which justify the survival of the process. By the so-called "stretch spinning" of Thiele-Bemberg, filaments of a fineness down to 2 deniers are obtainable with cuprammonium solutions from relatively large orifices. Such fine counts had not, up to now, been possible with viscose. The influence of the composition of the coagulating bath on the shape of the cross-sections of viscose silk has been studied, and the author showed in 1913 that when spinning filaments of about 8 deniers the quantity of sodium sulphate in the bath must be definitely in excess of the equivalent required to produce sodium bisulphate with the acid. A study of the effect of varying the concentration of the acid in the coagulating bath has now revealed the fact that the fineness of the filaments which can be spun is a function of the concentration of the acid. With a given viscose and a given size of jet orifice the minimum concentration of acid which must be present in the bath increases inversely as the square root of the denier required. More concentrated viscose solutions require either smaller orifices or higher concentrations of acid to give filaments of the same degree of fineness, and with the same viscose smaller orifices require lower minimum concentrations of acid than larger orifices. Hence a series of inter-related spinning conditions has been established which enable filaments of any degree of fineness down to 0·75 denier to be spun with accuracy.—J. F. B.

Cellulose complexes; Transformations of —— during the manufacture of artificial silk. W. Vieweg. Zellstoff und Papier, 1922, 2, 18—19.

The insoluble residue obtained by grinding cellulose with sodium hydroxide solution is the sodium alkyloxide of α-cellulose, and reacts as such with carbon bisulphide, benzoyl chloride, and the like. Alkali-cellulose having the formula, $(C_6H_{10}O_5)_3$,NaOH, is prepared by steeping cellulose in 18% sodium hydroxide solution and pressing the product; this product is unaffected by air or other oxidising agents. The cellulose xanthates capable of spinning contain the complexes $(C_6H_{10}O_5)_3$ and $(C_6H_{10}O_5)_4$. —L. A. C.

Cellulose acetates; Detection and determination of free sulphuric acid and sulphoacetates in ——. M. Entat and E. Vulquin. Ann. Chim. Analyt., 1922, 4, 131—135.

Free sulphuric acid is determined by digesting 10 g. of the cellulose acetate with 200 c.c. of water at 15° C. for 30 mins., filtering the mixture, and titrating the filtrate with standardised barium hydroxide solution, the end-point being determined electrometrically; the titration curve shows a sharp break when the free sulphuric acid is neutralised. Samples of normal cellulose acetate examined did not contain free sulphuric acid, and alkali and alkaline-earth sulphates have been mistaken for sulphuric acid by other observers. To determine sulphoacetates, 5 g. of the sample is heated with 50 c.c. of water for 5 hrs. in an autoclave at 125° C., and the sulphuric acid resulting from the hydrolysis of the sulphoacetate is then titrated as described above. All cellulose acetates prepared by methods in which sulphuric acid or its derivatives are used as catalysts contain sulphoacetic acid combined with the cellulose ester; the quantity of sulphuric acid present as sulphoacetic acid does not exceed 0·03% in the case of cellulose acetates of good manufacture.—W. P. S.

Patents.

Textile materials; Method of and apparatus for drying ——. H. Krantz. E.P. 179,409, 18.4.21. Addn. to 157,425 (J., 1922, 459 A).

The process described in the original patent is modified in that the final drying operation is effected by blowing warm air through the material after partially drying with steam. Suitable alterations are made in the various forms of apparatus previously described.—D. J. N.

Textile fibres; Manufacture of —— from stems of plants, especially nettles. J. Elster. G.P. 309,234, 22.2.18. Addn. to 305,409 (J., 1921, 689 A).

The fibres obtained as described in the chief patent are boiled with dilute caustic soda solution for about 2 hrs. in an open vessel or for a short time in a closed vessel under pressure, then washed with warm water, treated with soap solution to remove vegetable glue and other impurities which would interfere with the spinning of the fibres, washed successively with hot water and cold water, and dried.

Wool, fur, hair, and other materials; Process for protecting —— from moths. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 347,723, 25.9.19, and (B) 347,849, 13.7.20. Addns. to G.P. 346,598.

(A) Wool and other materials which have been made resistant to moth by treatment with hydrogen silicofluoride, other complex acids or their salts (*cf.* E.P. 173,536; J., 1922, 138 A), are after-treated with metallic salts capable of forming insoluble compounds with these complex inorganic acids, so that the treated material retains its moth-resisting properties even after the usual processes of washing, fulling, hot pressing, treatment with acids, etc. (B) Wool, fur, hair, and the like are rendered resistant to moths by treatment even with a cold liquor containing a complex inorganic acid, such as hydrogen silicofluoride, phosphotungstic acid, titanium-hydrofluoric acid, or hydrofluoric acid or one of its salts or double salts, if to the liquor is also added an assistant such as sodium sulphate, sodium chloride, an acid such as sulphuric or formic acid, or a metallic mordant such as a salt of chromium, aluminium, tin, zinc, or antimony.—A. J. H.

Wool, hair, and feathers; Process for increasing the strength and elasticity of ——. J. Korselt. G.P. 350,803, 18.4.20. Addn. to 349,179 (J., 1922, 410 A).

Neutral, alkaline, or acid solutions of decomposition products of alkaloids, *e.g.*, derivatives of pyridine, piperidine, pyrrolidine, quinoline, isoquinoline, phenanthrene, morpholine, or purine can be employed, either under normal or increased pressure, for treating wool, hair, or feathers as described in the chief patent.—L. A. C.

Carotting hairs; Process for ——. Soc. Pichard Frères. E.P. 163,297, 28.4.21. Conv., 15.5.20.

The skins "in the hair" are moistened with pure water, or water containing an antiseptic, such as formaldehyde, stacked hair against hair for several hours, and then exposed to sufficient cold by, *e.g.*, immersing them for a few seconds in liquid oxygen, nitrogen, or air, to freeze the water which has penetrated into the medullary ducts of the hairs. This causes the hairs to burst, and thereby improves their felting qualities. The process may also be applied to hairs which have been removed from the skin.—D. J. N.

Fibrous materials; Process for boiling —— and a device for carrying out the process. A.-G. der Maschinenfabr. Escher, Wyss und Co. E.P. 168,304, 4.7.21. Conv., 21.8.20.

Fibrous material is treated with a hot liquor within an upright boiler, provided with a supply pipe at the top, a discharge pipe connected with an annular space at a level below the top, and a pipe at the bottom which may serve either as a supply pipe or discharge pipe. The two upper pipes are provided with non-return valves, and by means of a single cross-over device the valves can be so operated that the liquor is introduced at the top, flows downwards, and is discharged at the bottom or is introduced at the bottom, flows upwards, and is discharged through the pipe connected with the annular space. The direction of flow of the liquor in the preheater connected with the boiler remains always the same.—A. J. H.

Fibrous pulp material; Process of preparing ——. C. and J. Bache-Wiig. U.S.P. 1,418,353, 6.6.22. Appl., 21.8.20.

In the preparation of paper pulp, straw-like substances containing ligneous matter are chemically softened, subjected to treatment in a kollergang (edge-runner), digested with a liquor containing a mixture of acid and alkaline compounds, and then further subjected to a second treatment in an edge-runner.—A. J. H.

Thin bands [cellulose film] to be used in the manufacture of cigaratte mouthpieces; Manufacture of ——. Chem. Fabr. von Heyden A.-G. E.P. 157,126, 8.1.21. Conv., 5.3.14.

A mixture containing 1 pt. of cellulose acetate, 5—15 pts. of bronze powder, and 40 pts. of acetone is sprayed in a uniform thin layer over a steel cylinder, heated slightly internally, which slowly revolves so that the coagulated film can be continuously removed. Films having a thickness of less than 0·05 mm. can be obtained, and they do not easily tear when used as a substitute for metallic foil in cigarette machines.—A. J. H.

Nitrocellulose; Manufacture of compound sheet material from ——. C. Claessen. E.P. 156,096, 22.12.20. Conv., 3.9.19. Addn. to 155,778 (J., 1922, 459 A).

A NON-INFLAMMABLE nitrocellulose composition suitable for use as a binding material for balata driving belts or as a floor covering is obtained by dissolving nitrocellulose in the liquid non-volatile tricresyl esters of phosphoric or thiophosphoric acid or their halogen substitution products, and adding suitable filling materials. A satisfactory composition contains 20—25% of nitrocellulose, 28—35% of tricresyl phosphate, 15—20% of chalk or the like, 2—5% of English red, and 35—15% of finely ground sawdust.—D. J. N.

Alkali cellulose and the like; Apparatus for use in reducing ——. A. Kämpf, Assr. to Die Köln-Rottweil Akt.-Ges. E.P. 157,982, 12.1.21. Conv., 13.1.20.

A MACHINE suitable for reducing alkali-cellulose to a loose flocculent state before treatment with carbon bisulphide, for conversion into viscose, consists of a saddle-shaped trough having teeth or projections on the bottom, and within which beaters or paddles rotate. Each beater has on its periphery a continuous row of teeth which work between the teeth on the bottom of the trough, so that fibrous material placed therein is subjected to a shearing action. The shearing action is increased by the addition of grooves or channels across the toothed portion of the trough.—A. J. H.

Viscose; Removal of sulphur compounds from coagulating baths and waste gases produced in the manufacture of ——. E. Schülke. G.P. 346,829, 29.3.20.

THE liquors used for coagulation and the waste gases are treated with hydrochloric acid containing free chlorine, whereby sulphur is precipitated in a form which can be easily separated by filtration.
—A. J. H.

Cellulose acetate; Manufacture of plastic materials or articles having a basis of ——. H. Dreyfus. E.P. 179,208, 4.11.20.

CELLULOSE acetate in a dry or air-dry condition is kneaded or mixed with not more than 50% of its weight of a plastifying agent, which is not saponified by water, the temperature during the mixing operation being kept at 100°—150° C. or higher. Fillers or colouring agents may be added if desired, together with substances capable of neutralising traces of acid, *e.g.*, urea, methylurea, etc. The molten mixture is run into moulds, or worked up by any of the usual processes. Suitable plastifying agents are the xylene-alkyl-sulphonamides described in E.P. 132,283 (J., 1919, 896 A), in admixture, if desired, with triphenyl or tricresyl phosphate. This process, in which no volatile solvents are used, gives strong celluloid-like masses which require no seasoning.—D. J. N.

Artificial filaments, threads and films; Manufacture of ——. British Cellulose and Chemical Mfg. Co., Ltd., C. W. Palmer, and W. A. Dickie. E.P. 179,234, 4.1.21.

OTHER substances such as acetone, diacetone-alcohol, alcohol, acetic acid, formic acid, aqueous solutions of zinc chloride, or mixtures of these, which are soluble in water, and have a solvent action on cellulose acetate, may be used in place of thiocyanates in the coagulating bath for cellulose acetate dissolved in water-soluble organic solvents (*cf.* E.P. 177,868; J., 1922, 459 A). Suitable concentrations of these substances per 100 pts. of water are acetone 10—50 pts., alcohol 100 pts., diacetone-alcohol or acetic acid 5 pts.—D. J. N.

Cellulose ethers; Process of making ——. J. M. Donohue, Assr. to Eastman Kodak Co. U.S.P. 1,415,023, 9.5.22. Appl., 9.6.21.

CELLULOSE is soaked in caustic soda solution until mercerised, and is then mixed with powdered alkali. Excess of liquor is removed by pressure, and the cellulose in the resulting mixture etherified in the usual way.—D. J. N.

Cellulose-ether solvent and composition. W. R. Webb, Assr. to Eastman Kodak Co. U.S.P. 1,418,413, 6.6.22. Appl., 10.1.21.

A CELLULOSE ether is dissolved in a mixture of carbon tetrachloride and a monohydroxy aliphatic alcohol with less than 3 carbon atoms in the molecule, to form a fluid film-forming composition.
—W. C.

Plastic masses. Ges. für Verwertung Chem. Produkte m.b.H. G.P. 351,103, 27.11.19.

PLASTIC masses are prepared from a mixture of a cellulose ester (especially nitrocellulose) and a naphthenic acid. The properties are largely dependent on their content of naphthenic acid. Such masses are suitable for use in the preparation of films and medical bandages, etc.—A. J. H.

Friction composition and process for making same. W. Achtmeyer. U.S.P. 1,418,607, 6.6.22. Appl., 10.3.21.

A BRAKE friction composition consists of asbestos impregnated with a condensation product of phenol and methylenediphenyldiamine.—A. J. H.

Paper; Bleaching of "stuff" or fibres in the manufacture of —— *and apparatus therefor.* W. H. Salmon. E.P. 178,209, 14.1.21.

THE removal of liquor from bleached paper pulp is accelerated and pulp of a more uniform colour obtained by subjecting the underside of the partially drained "stuff" to the action of a vacuum. The drainage bins are fitted with a tiled draining floor, and means are provided for exhausting the air from the space between this draining floor and the main floor of the bin. Provision is also made for removing the drainage liquor.—D. J. N.

Paper pulp; Method for the manufacture of —— *and apparatus therefor.* V. Bernot and P. R. Fournier. E.P. 178,962, 1.2.21.

A PROCESS is described for the manufacture of paper pulp from rags and other fibrous material, in which the raw material and digestion liquor are fed continuously into a horizontal digestion cylinder, suitably heated and fitted internally with a screw conveyor, the pitch and rotation of which determine the duration of the digestion treatment; the cylinder wall is recessed to accommodate a wheel provided with teeth of such a shape that they engage with the thread of the screw conveyor and force the material under treatment to go forward as the screw rotates. The apparatus for separating the fibres consists of a cylinder adjacent to and in alinement with the digestion cylinder, and is fitted internally with a revolving knife cutter and a number of vertical partitions provided with openings decreasing in width from the first partition to the last, *e.g.*, the first partition may have openings several cm. wide, while the last has slits of such a width as to permit only of the passage of single fibres. Between these partitions and clearing them by about 2 mm. are rotating stirring members to disintegrate the fibrous material; the pulp and liquor leaving the apparatus are separated in a filter press; the pulp is washed, while the liquor passes back into the digestion cylinder.—D. J. N.

Paper and paper containers; Rendering —— greaseproof. W. L. Wright, Assr. to Seabright Co., Inc. U.S.P. 1,417,708, 30.5.22. Appl., 11.7.18.

Paper material is coated by means of a nearly saturated aqueous solution of sugar containing a soluble adhesive.—A. J. H.

Sulphite[-cellulose] liquor; Continuous process for decomposing waste ——. K. Mörch. U.S.P. 1,415,843, 9.5.22. Appl., 10.5.20.

Sulphite-cellulose waste liquor is continuously passed through a chamber in which the temperature and pressure are so regulated as to cause the liquor to decompose.—D. J. N.

Sulphite-cellulose waste liquor; Utilisation of the free sulphurous acid and that combined with lignin present in ——. E. Mürbe. G.P. 347,658, 21.4.14. Addn. to 344,955 (J., 1922, 290 A).

On entering the separator, as described in the chief patent, the sulphite-cellulose waste liquor is mixed with a substance such as sodium bisulphate, in a finely divided form, which assists the liberation of sulphur dioxide. Suction is applied to the condenser attached to the separator so as to avoid back pressure. Nearly 30% of the sulphur present in the original sulphite liquor can thus be recovered in a useful form. Almost perfect separation is obtained of free and loosely combined sulphur dioxide and also of that combined with lime. All the calcium present is recovered as calcium sulphate in a finely divided state.—A. J. H.

Viscose solutions; Manufacture of ——. W. P. Dreaper. U.S.P. 1,418,135, 30.5.22. Appl., 14.11.21.

See E.P. 178,152 of 1920; J., 1922, 459 A.

Threads or filaments; Manufacture of artificial ——. W. P. Dreaper. U.S.P. 1,418,136, 30.5.22. Appl., 15.11.21.

See E.P. 171,719 of 1920; J., 1922, 52 A.

Expressing liquid from fibrous substances, such as mechanical pulp or cellulose; Rotary apparatus for ——. Aktiebolaget Karlstads Mekaniska Verkstad. E.P. 159,204, 19.2.21. Conv., 25.2.20.

Paper-pulp; [Mechanical] process for manufacture of ——. H. Steinhilber. E.P. 180,097, 3.3.21.

Paper making machines; Fourdrinier ——. S. Milne. E.P. 180,504, 7.4.21. Addn. to 128,425.

Paper; Process of [and means for feeding the pulp to the forming wire in] apparatus for manufacturing ——. H. Wade. From International Paper Co. E.P. 180,766, 4.3.21.

See also pages (A) 536, *Bituminous products, felt, etc.* (U.S.P. 1,417,835 and 1,417,837—41). 543, *Dyeing fabrics containing cellulose acetate* (E.P. 178,946); *Dyeing cellulose acetate* (E.P. 179,384). 546, *Aluminium compounds for sizing paper etc.* (G.P. 345,315). 548, *Protectively treating materials* (U.S.P. 1,418,609—10).

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Hypochlorite bleaching solutions. Royer. *See* VII.

Patents.

Dyeing [union fabrics containing cellulose acetate fibres]; Process of ——. British Cellulose and Chemical Mfg. Co., Ltd., J. F. Briggs, and L. G. Richardson. E.P. 178,946, 27.1.21.

The superficial saponification of cellulose acetate silk previous to or during the dyeing operation (E.P. 169,741, 175,485, and 175,486; J., 1921, 808 A; 1922, 289 A) is applied in the production of level shades of colour on textile fabrics containing mixtures of cellulose acetate silk with cotton or other cellulose fibres, natural or artificial. The union fabric is worked in a dye-bath, preferably containing small quantities of soap and/or soda ash, at a temperature not exceeding 50° C. until the cotton or other cellulose fibre has become fully dyed, leaving the cellulose acetate threads but slightly coloured. The temperature of the bath is then raised to 75°—80° C. and a quantity of alkali, *e.g.*, up to 10% NaOH on the weight of the cellulose acetate, added. As saponification of the cellulose acetate proceeds, the colour bleeds from the cotton on to the cellulose acetate threads, and, by controlling the reaction, level shades of colour may be obtained, or any desired difference in shade on the cellulose acetate and cotton. Any of the saponifying agents described in the above patents may be employed.—D. J. N.

Acetyl cellulose [cellulose acetate]; Process for dyeing ——. Burgess, Ledward, and Co., Ltd., and W. Harrison. E.P. 179,384, 21.3.21.

Cellulose acetate may be dyed with dyestuffs, for which, in the ordinary way, it has little or no affinity, by employing them in colloidal solution, obtained by adding a colloid, *e.g.*, gelatin, casein, saponin, or their hydrolytic products, to the dye-bath, followed by a precipitant (other than a metallic chloride), preferably one which is itself absorbed by cellulose acetate. Suitable precipitants for basic colours are molybdates, tungstates, stannates, tannic acid, salts of phenols, etc., and for acid colours, direct cotton colours, sulphur and vat colours, an organic compound containing basic groups, *e.g.*, a salt of aniline, benzidine, dianisidine, etc. The method of procedure is, for example, as follows: 100 g. of cellulose acetate silk is worked for 5 mins. in a bath containing 2 g. of indigo, 8 g. of caustic soda, 5 g. of sodium hydrosulphite, 2 g. of glue, 2000 c.c. of water at 60°—70° C.; a solution of 0·5 g. of dianisidine in 4 c.c. of glacial acetic acid and 200 c.c. of water is then added in successive small quantities. The dyed silk is taken out of the bath, allowed to oxidise in the air, and is then washed and dried. This process is particularly useful for sulphur and vat colours, but is less satisfactory with direct cotton colours, as the dyeings with this latter group of colours are not fast to soap or alkaline liquors.—D. J. N.

Dyeing skins, hairs, and the like; Process for ——. O. Kaltwasser and H. Oehrn, Assrs. to A.-G. für Anilin-Fabr. U.S.P. 1,416,646, 16.5.22. Appl., 7.12.21.

The material is treated in the presence of a suitable oxidising agent with a solution containing a 5-nitro-2-amino-1-hydroxy derivative of the benzene series. —D. J. N.

Dyeing machine. E. S. Halter. U.S.P. 1,417,825, 30.5.22. Appl., 5.2.21.

A machine suitable for dyeing material in the form of skeins consists of a vat over which are arranged skein carriers which also oscillate between limits of movement approximately equidistant from the surface of the liquor contained in the vat. The skeins are suspended on reels which revolve on the carriers.—A. J. H.

Dyeing; Process of ——. H. Toepfer, Assr. to The Grasselli Chemical Co. U.S.P. 1,417,869, 30.5.22. Appl., 4.8.21.

ANIMAL fibres are dyed by means of cobalt salts in conjunction with azo dyestuffs derived from nitro-*o*-aminophenols.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric oxide; Peroxidation of —— and the recovery of oxides of nitrogen from mixtures with air. E. Briner, S. Niewiazski, and J. Wiswald. J. Chim. Phys., 1922, **19**, 290—309.

THE authors' experiments confirm the views of Raschig and of Le Blanc (J., 1905, 923; 1906, 869) that the formation of nitrite from a mixture of gases containing nitric oxide and nitrogen peroxide by alkali occurs through nitrous anhydride. The oxidation of nitric oxide at low temperatures takes place directly to nitrogen peroxide without the intermediate formation of nitrous anhydride. The best means of effecting a complete recovery of oxides of nitrogen from dilute gaseous mixtures such as are obtained in the electric arc process of nitrogen fixation, consists in submitting the gas to a very low temperature, provided that the technical difficulties can be overcome; without such a low temperature very large oxidation chambers will be necessary. (*Cf.* J.C.S., Aug.)—J. F. S.

Phosphoric acid; [Determination of] composition of commercial ——. W. H. Ross, C. B. Durgin, and R. M. Jones. J. Ind. Eng. Chem., 1922, **14**, 533—535.

THE methods of analysis suitable for the determination of impurities in phosphate rock are not satisfactory in the case of phosphoric acid. A series of tests have therefore been devised which are applied after the impurity has been concentrated by the removal of the free acid by volatilisation or precipitation of the impurity, which may be Ca, Fe, Al, Mn, Pb, As, S, Cl, F. For the determination of the alkali metals it is, however, necessary to precipitate the phosphoric acid. Calcium is precipitated as sulphate by excess of 95% ethyl alcohol and converted into oxalate. Aluminium is weighed as phosphate, being precipitated by a slight excess of calcium chloride over that required to form the soluble calcium diphosphate. Colorimetric tests are given for manganese and lead. The results of a series of analyses by these methods are tabulated. —C. I.

Ammonia; Production of —— by the sodium cyanide method. F. E. Bartell. J. Ind. Eng. Chem., 1922, **14**, 516—521.

THE briquettes prepared by the Bucher process, in which nitrogen is passed through a heated mixture of coke, soda ash, and iron, contain sodium cyanide with some cyanate. The cyanide and cyanate are converted into ammonia by the action of steam. By hydrolysis at a low temperature (100°—200° C.) sodium formate is formed, with evolution of heat. At temperatures above 200° C. the sodium salt obtained is oxalate, and above 400° C., carbonate. It is best to effect the conversion into carbonate, as the briquettes, after steaming, can then be returned to the cyanising apparatus. In order to avoid the formation of ferrocyanide, superheated steam must be used. The temperature at the beginning of steaming should be 260° C. About 50% excess steam over the theoretical should be used. If the steam is admitted too slowly ferrocyanide will be formed, if too rapidly, ammonium carbonate. The temperature should not reach 650° C., at which point ammonia begins to decompose. (Sodium ferrocyanide is decomposed at 475° C.) Trials with retorts holding from 190 lb. up to 640 lb. of briquettes showed that with proper temperature regulation on these lines 85—100% ammonia recovery could be obtained. A horizontal continuous steamer with screw conveyor gave promise of satisfactory results.—C. I.

Ammonium nitrate; Preparation of ——. Wurmser. Comptes rend., 1922, **174**, 1466—1468.

LE CHATELIER (J., 1921, 214 A) has previously given a square diagram showing the states of equilibrium between the four salts, ammonium chloride, sodium nitrate, ammonium nitrate, and sodium chloride in solution and the solid salts at 16° C. A similar diagram is now given for a temperature of 100° C., the curves being of similar shape. From them it is possible to determine the best experimental conditions for obtaining the maximum yield of ammonium nitrate from a solution of the four salts.—W. G.

Hypochlorite bleaching solutions; Determination of the available chlorine in ——. J. Royer. Ann. Falsif., 1922, **15**, 146—148.

FOR the estimation of available chlorine in bleaching solutions the method of Poncius is recommended as being rapid and exact. It consists in titration with a solution of potassium iodide after the addition of sodium bicarbonate. At first the iodide is oxidised to iodate by the free chlorine, but as soon as this reaction is completed the next drop of iodide solution reacts with the iodate, and iodine is liberated and detected by means of starch paste.—W. G.

[Sodium] bisulphite; Method for the determination of ——. F. Kühl. J. Soc. Leather Trades Chem., 1922, **6**, 199—200.

Two grams of the bisulphite is dissolved in water and titrated with $N/1$ sodium hydroxide (a c.c.). 10 c.c. of neutral 40% formaldehyde solution is added and the sodium hydroxide liberated is titrated with $N/1$ hydrochloric acid (b c.c.). If $a=b$ the impurities are neutral. If $a>b$ the difference is calculated as $NaHSO_4$ and when $b>a$, $b-a$ is calculated as Na_2SO_3. —D. W.

Calcium carbide; Calculation of power consumption in the manufacture of ——. H. Furusaki. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 24—36.

IN commercial operation the quantities of raw materials used per metric ton of carbide of 71·4% purity are 510 kg. of charcoal, 200 kg. of anthracite, 980 kg. of quicklime, and 70 kg. of electrode carbon. There is a loss of 450 kg., and the quantity of heat to be supplied by the electric power is 2,350,000 kg.-cals., corresponding to 2733 kw.h. Of a total 1054 kw. supplied to the furnace 336·5 kw. was used to cover losses by radiation, conduction, etc., of the furnace, by the resistance in the conductors and electrodes, etc., and 717·5 kw. was consumed for the production of carbide. The heat efficiency of the electric power supplied to the furnace is, therefore, 68·1%, and the power necessary for the production of a metric ton of 71·4% commercial carbide is 4013 kw.h. A further consumption of 825·1 kw. occurs at the upper surface of the charge, and the actual heat efficiency of the furnace is therefore 40·5% —K. K.

Carbon dioxide; Velocity of absorption of —— by alkaline solutions. P. Riou. Comptes rend., 1922, **174**, 1463—1466.

The velocity of absorption of carbon dioxide from air by solutions of potassium carbonate increases with the concentration of the solution at first very rapidly to a maximum and then slowly decreases. The presence of potassium bicarbonate causes a very marked diminution in the velocity of absorption, but the effect of potassium chloride is less marked. In every case rise in temperature is accompanied by an increase in the velocity of absorption. Other factors being equal, the velocity of absorption is practically proportional to the concentration of the carbon dioxide in the air mixture.—W. G.

Calcium carbonate; Inadequacy of "A.R." test for alkalis in ——. W. Singleton and H. Williams. Analyst, 1922, **47**, 252—254.

Only about 50% of the total extractable sodium carbonate is washed out on boiling 5 g. of calcium carbonate with 50 c.c. of water for 10 mins. The alkalis present in 5 g. of "A.R." calcium carbonate were therefore determined by the Lawrence Smith method (Amer. J. Sci., 1871, **50**, 269), and the amount of sodium carbonate obtained was over ten times that obtained by the "A.R." method. The method was checked by decomposing 5 g. of the calcium carbonate with hydrochloric acid and precipitating the calcium twice with ammonium carbonate and ammonium oxalate. Substantially the same result was obtained. It therefore appears that only about 10% of the alkali carbonates present in the calcium carbonate is removed by one extraction with water.—H. C. R.

Aluminium salts; Reactions of sodium hydroxide with ——. E. Grobet. J. Chim. Phys., 1922, **19**, 331—335.

On addition of sodium hydroxide to dilute solutions of aluminium nitrate, aluminium hydroxide, sodium metaluminate, and sodium ortho-aluminate are successively formed. When dilute solutions of aluminium sulphate or chloride or potash alum are used, aluminium hydroxide, basic sodium aluminate, $Al(ONa)_3,Al(OH)_3$, and sodium ortho-aluminate are formed successively. Concentrated solutions of aluminium chloride, nitrate, or sulphate produce under the same treatment a basic salt of the type, $AlX_3,Al(OH)_3$, which is followed by the hydroxide, metaluminate, and ortho-aluminate. Concentrated solutions of potash alum yield a basic salt, $Al_2(SO_4)_3,2Al(OH)_3$, aluminium hydroxide, a basic aluminate, $Al(ONa)_3,Al(OH)_3$, and the ortho-aluminate.—J. F. S.

[*Commercial copper sulphate;*] *Determination of copper and iron* [*in* ——] *iodometrically.* A. Wöber. Z. angew. Chem., 1922, **35**, 336—337.

Five g. of the sample is dissolved in water and the solution is diluted to 100 c.c. in a graduated flask. Ten c.c. is pipetted into a stoppered conical flask, diluted to 50 c.c., heated to 70° C., and treated with 3—5 c.c. of ammonia (sp. gr. 0·944). A current of air is passed through the solution for 15 mins. to oxidise the iron and copper to the cupric and ferric states, the ammonia is boiled off, and the solution treated with hydrochloric acid and potassium iodide in an atmosphere of carbon dioxide. After standing for 20 mins., the liberated iodine is titrated with thiosulphate to obtain the sum of the copper and iron. Copper alone is determined in a second portion which is treated as above except that the iron is removed by filtration, before acidifying the solution after the air treatment. Re-precipitation of the iron is necessary to obtain all the copper in the filtrate.—A. R. P.

Lead acetate; Solubility of —— by the floating equilibrium method. M. L. Dundon and W. E. Henderson. J. Amer. Chem. Soc., 1922, **44**, 1196—1203.

A new method of determining solubility is described, which consists in placing a float, calibrated so that it will just sink in a solution of known composition of the substance under investigation, into a weighed quantity of the saturated solution and adding the solvent until the float just sinks. The quantity of solvent added is noted, and from this the weight of solution taken, and the calibration constant of the float the solubility is readily calculated. This method has been applied to the determination of the solubility of lead acetate in water at temperatures from 0° C. to 50° C. The following values in g. of lead acetate per 100 g. of water are recorded: 0° C., 19·7; 5° C., 23·7; 10° C., 29·3; 15° C., 35·6; 20° C., 44·3; 25° C., 55·2; 30° C., 69·7; 35° C., 88·9; 40° C., 116·0; 45° C., 153·0; 50° C., 221·0. The method is capable of considerable speed and of great accuracy.—J. F. S.

Carbon; Preparation of —— from carbon monoxide by means of a catalyst. J. P. Wibaut. Rec. Trav. Chim., 1922, **41**, 400—401.

Carbon prepared by passing carbon monoxide over iron oxide in a porcelain tube heated to 450°—470° C., gave about half its weight of iron oxide on ignition. During the reaction, the catalyst appears to distribute itself fairly uniformly throughout the carbon which is formed, and all attempts to free the product from metallic oxide were unsuccessful.

Patents.

Nitric acid; Process for production of concentrated ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 170,840, 13.10.21. Conv., 27.10.20.

In the usual process for the production of concentrated nitric acid from liquid oxides of nitrogen with oxygen and water, the first-named being in excess, two layers of liquid are formed, the upper non-aqueous layer containing nitric acid and excess of oxides of nitrogen and the lower layer being 80—90% nitric acid. Whilst hitherto the former has been used for the production of acid, and the latter returned to the process, the reverse procedure is now claimed to be preferable, the cost of concentrating the aqueous acid being more than offset by the nitrogen loss involved in the former practice. A little of the aqueous layer may be returned to the reaction tower along with the upper layer.—C. I.

Barium hydrate [*hydroxide*]; *Continuous process for the manufacture of ——.* C. Deguide. E.P. 174,052, 20.12.21. Conv., 13.1.21.

In the production of barium hydroxide by the process described in E.P. 110,537 (J., 1918, **30** a) a better yield of the hydroxide is obtained by alternately forming and decomposing tribarium silicate, $SiO_2,3BaO$ or silicate intermediate between the tri- and di-barium compounds than by the use of the dibarium silicate as described earlier (*loc. cit.*).
—H. R. D.

Sodium ferrocyanide; Manufacture of ——. F. F. Delarozière. E.P. 179,982, 17.1.21.

In the manufacture of the sodium salt from calcium ferrocyanide by double decomposition, sodium sulphate is substituted for sodium carbonate. The resulting precipitate is more easily washed. Slightly less sulphate than the equivalent of the calcium ferrocyanide is used, and, after filtration, the decomposition is completed with sodium carbonate in order to render the liquor alkaline. Salt may be added to the liquor to reduce the solubility of the sodium ferrocyanide, or impure salt-cake may be used for the decomposition.—C. I.

Gases [e.g., hydrogen]; Process for purifying ——. J. Y. Johnson. From Badische Anilin und Soda Fabrik. E.P. 180,024, 14.2.21.

To remove carbon oxysulphide and allied substances from gas which has already been freed from hydrogen sulphide, the gas is treated with activated charcoal made alkaline with, for example, ammonia. Oxygen may be introduced into the gas stream in order to assist in the oxidation of the sulphur compounds. The process is specially applicable to the purification of hydrogen to be used in the synthesis of ammonia.—A. R. P.

Hydrogen and nitrogen; Process to produce mixtures of ——. E. Szarvasy. U.S.P. 1,417,952, 30.5.22. Appl., 12.2.15.

A mixture of nitrogen and methane is heated in a decomposing chamber containing glowing carbon from a previous decomposition. The gases are so proportioned that the mixture produced contains hydrogen and nitrogen in the ratio necessary for ammonia synthesis.—C. I.

Ammonium sulphate; Process of obtaining —— by the interaction of ammonium carbonate and calcium sulphate. Soc. Ind. de Prod. Chim. G.P. 345,256, 29.12.20. Conv., 22.7.20.

Calcium sulphate is added to ammonium carbonate solution which has been previously warmed to a temperature above 30° C., and the mixture is kept at about 70° C. until the reaction is complete.

Sodium pentaborate; Process for production of —— direct from boron ores. A. A. Kelly and B. D. Jones. E.P. 180,110, 12.3 and 25.10.21.

Sulphur dioxide is introduced into a mixture of 100 pts. of boronatrocalcite (40% B_2O_3), and 400 pts. of water. When the separation of boric acid according to the equation, $Na_2O+2CaO+5B_2O_3+3SO_2=2CaSO_3+Na_2SO_3+5B_2O_3$, is complete, the supply of sulphur dioxide is stopped, the calculated amount of boronatrocalcite is added to the reaction mixture, and the latter heated to boiling, whereby sodium pentaborate is formed according to the equation,

$$2(Na_2SO_3+5B_2O_3)+Na_2O+2CaO+5B_2O_3= 2CaSO_3+3(Na_2O+5B_2O_3),$$

and may be recovered by crystallisation.—H. R. D.

Carbon bisulphide; Manufacture of ——. Courtaulds, Ltd., and A. E. Delph. E.P. 180,175, 23.4.21.

Retorts and other parts of the plant made of iron, or steel, are protected against the action of sulphur or sulphur compounds by a thin coating of aluminium.—H. R. D.

Cyanides; Process of producing ——. F. von Bichowsky and J. Harthan. U.S.P. 1,417,702, 30.5.22. Appl., 25.10.20.

Titanium nitrides are heated with an alkali salt in presence of a carbide of iron, but without free carbon.—C. I.

Potassium salts; Process for obtaining —— from natural potassium compounds. D. D. Jackson. U.S.P. 1,417,919, 30.5.22. Appl., 29.6.20.

The material is mixed with lime and a haloid salt, and heated at a temperature below the clinkering temperature of the mixture, but high enough to cause rapid volatilisation of the potassium halide formed.—H. R. D.

Beryllium [glucinum] compounds; Production of ——. Process for production of zirconium compounds. L. Burgess. U.S.P. (A) 1,418,527 and (B) 1,418,528, 6.6.22. Appl., 16.8.21.

An oxidised ore of (A) glucinum or (B) zirconium is heated with carbon and the compound produced is then treated with gaseous hydrochloric acid to obtain glucinum or zirconium chloride.—H. R. D.

Aluminium compounds for sizing paper and other purposes; Preparation of ——. G. Muth. G.P. 345,315, 4.12.19. Addn. to 319,420 (J., 1920, 517 A).

The treatment of aluminium compounds as described in the chief patent is more expeditiously carried out in closed vessels under a high temperature and pressure.—A. J. H.

Hydrogen sulphide; Process for the removal of —— from gases. Ges. für Kohlentechnik m.b.H. G.P. 350,591, 26.10.19.

The gas is washed with a solution of a copper salt, and the resulting copper sulphide is treated in suspension with a gas containing oxygen, under pressure, and with the aid of heat to oxidise it to copper sulphate. Other metallic salts can be used, *e.g.*, zinc salts, the metallic sulphide being treated with copper sulphate solution, and converted into the sulphate, whilst the copper sulphide produced is converted in sulphate as outlined above.—A. G.

Sulphuric acid; Manufacture of ——. E. A. Gaillard. E.P. 180,546, 10.5.21.

See G.P. 346,121 of 1921; J., 1922, 215 A.

Ammonium chloride from coal or shales. E.P. 169,948. *See* IIA.

VIII.—GLASS; CERAMICS.

Clays; Use of electrolytes in the purification and preparation of ——. H. G. Schurecht. U.S. Bureau of Mines, Tech. Paper 281, 1922. Pp. 47.

Slips were prepared from clay, water, and electrolytes in varying proportions and their viscosities measured by determining the time necessary for

250 c.c. of slip to pass through an orifice of $\frac{3}{32}$ in. In order to maintain minimum viscosity in clay slips in which the clay and water contents varied, but in which the water content exceeded 50%, it was much more important to keep the ratio of electrolyte to clay constant than to keep the ratio of electrolyte to water constant. When sodium hydroxide was added in small quantities to Georgia kaolin the decrease in viscosity was gradual up to a certain point, but on further addition of the electrolyte there was a sudden drop to minimum viscosity. The limits within which sodium hydroxide produced minimum viscosity were small, but the limits within which sodium silicate and sodium carbonate produced minimum viscosity were relatively large. In presence of sufficient alkali to produce minimum viscosity, slip of a given viscosity contained 50—58% more clay per unit quantity of slip than when no alkalis were added, but this result should be checked by large-scale clay washing tests. The effect of completely or partly neutralising with sulphuric acid a clay slip containing sodium hydroxide as the deflocculating agent was studied. The viscosity of Florida and N. Carolina kaolins was increased when the slip was neutralised with sulphuric acid equivalent to the sodium hydroxide first added, the increase in plasticity that sometimes has caused trouble to kaolin refiners being due to this increase in viscosity. In some cases black discoloration of the dry kaolin is caused by adding an excess of sulphuric acid. Both these defects are reduced by adding less sulphuric acid than the equivalent of the sodium hydroxide used, the amount required varying with different clays. With Florida and Georgia kaolins the sedimentation was much slower after the slips had been treated with sodium hydroxide and sulphuric acid than it was before treatment. The deflocculated kaolin could not be filtered successfully, as the fine particles either passed through or clogged the filter. Ready filtration was possible after partially neutralising the alkalinity of the kaolin by adding sulphuric acid. The rate of disintegration in water of cubes containing equivalent parts of filtered kaolin and flint was slower than when untreated kaolin was used. Care should be taken to have the proper ratio of acid to alkalis in the kaolin slip, because any variation of acid causes the kaolin to act differently towards subsequent alkali treatment, those slips which have received the larger additions of acid requiring more alkali to produce the same degree of dispersion upon again deflocculating. Electrolytes added to the clays in the plastic state increased the dry strength, the order of effectiveness being sodium hydroxide, sodium silicate, sodium carbonate, tannic acid, and calcium hydroxide. Alkalis lowered the percentage of water of plasticity of ball clays. Acids at first increased, but when in excess decreased, the water necessary to work the bodies. Calcium hydroxide increased the water of plasticity. The drying shrinkage of mixtures of equal parts of clay and flint was decreased for all the clays examined (except Georgia kaolin and Kentucky ball clay) by adding 1 or 2% of alkalis. Sulphuric acid in small percentages increased, and in larger percentages decreased the drying shrinkage. Tannic acid and calcium hydroxide increased the drying shrinkage. The shrinkage on firing to cone 01 was lowered when small percentages of caustic soda were added, and increased when larger quantities were used. The porosity after firing was decreased and the density increased when sodium hydroxide was used. The strength after firing to cone 8 was increased by adding the following electrolytes (arranged in order of decreasing effectiveness) to the bodies in the plastic state: sodium hydroxide, sodium silicate, sodium carbonate, tannic acid. The dry strength of a clay was increased by wet grinding for two hours, by adding 1% sodium hydroxide when grinding, removing the coarse material by screening through 150-mesh sieve, and by adding 1% of dextrin. The plasticity of all clays was increased by wet grinding, screening, and adding 1% of dextrin. The addition of 1% of sodium hydroxide caused the clay to become tougher in the plastic condition and somewhat more difficult to mould. No scumming was caused by the soda if 1% of dextrin was added. The drying shrinkage and water of plasticity were increased, and the density was decreased, by wet grinding. The strength of the clays after firing to cone 2 was increased considerably by these treatments.

—H. S. H.

After-contraction test [*of fire-bricks*]; *Standardisation of the* ——. D. A. Jones. Report of the Refractory Materials Research Committee of the Institution of Gas Eng., June, 1922. Gas J., 1922, 158, 840—844.

Discordant results are obtained for the after-contraction of a firebrick when the tests are made according to the standard specification method. The errors are not eliminated by using whole bricks for the test, the chief source of error being the dislocation of the surface of the brick after firing. Scratches were made on the specimen to be tested and the distance between them measured with a travelling microscope before and after heating the brick for two hours at the specified temperature. Owing to the more equal firing in the laboratory furnace small test pieces give more concordant results than the whole bricks, and are recommended for use in carrying out the test. Different bricks from the same batch exhibit differences in after-contraction due to uneven firing in the kiln during manufacture.—H. S. H.

Refractory materials; Thermal conductivity of —— *at high temperatures.* A. T. Green. Report of the Refractory Materials Research Committee of the Inst. of Gas Eng., June, 1922. Gas J., 1922, 158, 844—852.

A critical review of previous experimental work on the thermal conductivity of refractories is given. Nine bricks, placed with their lengths along the direction of the flow of heat, were built to form a wall, which was heated by a bauxitic plate heated by a carbon resistance furnace, the central brick being used as the test piece. The temperatures of the hot face and of the interior of the brick at two known depths were measured with thermocouples after the hot face had been maintained for about 9 hours at its final temperature. The diffusivity of the material was obtained from the formula

$$\frac{\theta_0-\theta}{\theta_0}=\frac{2}{\sqrt{\pi}}\int_0^{\frac{x}{2kt}} e^{-B^2}\,dB \text{ where } B=\frac{x}{2\sqrt{kt}},\ k=\text{the}$$

diffusivity, θ_0=temperature of hot face, θ=temperature after t secs. of an isothermal plane at a distance, x, from the hot face. The conductivity was obtained by multiplying the diffusivity by the product of the specific heat and the apparent specific gravity of the material. The results obtained were much lower (about one-half) than those obtained by calorimetric methods. The thermal conductivity of silica and fireclay materials increased with rise of temperature. The conductivity of magnesite was greater than that of firebricks at temperatures below 1000° C., but it decreased with rise of temperature. The variation of diffusivity with temperature is shown, and it is suggested that in the carbonising industries the diffusivity is the best guide to the thermal efficiency of the material, while thermal conductivity is the important factor where insulating properties are desired.—H. S. H.

PATENTS.

Opal glass; Composition for ——. A. L. Duval d'Adrian. U.S.P. 1,419,032, 6.6.22. Appl., 27.6.21.

A COMPOSITION to be added to the usual glass mixture comprises a complex fluoride of an amphoteric element with an alkaline-earth fluoride.—H. S. H.

Tungsten or molybdenum carbide or a mixture of their carbides; Manufacture of pieces of any desired size or shape of —— *for tools and articles of all kinds.* Lohmann-Metall, G.m.b.H. E.P. 157,749, 10.1.21. Conv., 29.1.14. Addn. to 157,747 (*cf.* G.P. 289,066; J., 1916, 423).

THE moulded articles are produced from the powdered carbides by pressing in iron matrices, and after removal from these are heated in a reducing atmosphere to very near the melting point of the carbides.—H. S. H.

Refractory material and process of making the same. C. A. French, Assr. to International Harvester Co. U.S.P. 1,418,372, 6.6.22. Appl., 14.6.20.

A REFRACTORY compound is formed essentially from zirconium oxide and steatite.—T. A. S.

Refractory material and process of making same. R. W. Hull. U.S.P. 1,418,648, 6.6.22. Appl., 9.4.21.

A REFRACTORY material for surfaces subjected to intense heat comprises waste material left after concentrating disseminated chrome ore containing a mixture of silica, serpentine, and olivine, and united by a binder.—H. S. H.

Furnace; Heat-treating —— *and method* [*for earthenware*]. C. J. Kirk. U.S.P. 1,418,446, 6.6.22. Appl., 10.2.20.

THE earthenware is fired while traversing a firing chamber heated from several separate heat-sources regulated independently and creating well defined zones of heat.—H. S. H.

Tunnel kiln. E. P. Ogden, Assr. to J. B. Owens. U.S.P. 1,418,669, 6.6.22. Appl., 5.11.20.

A TUNNEL kiln is provided with an auxiliary chimney stack or fan, in addition to the main one. Vapours which have been introduced for special purposes are removed from the kiln by means of the auxiliary stack or fan without interfering with the main draught.—A. B. S.

Kiln for burning refractory bricks, especially lime-bonded silica or Dinas bricks, and other ceramic ware. H. Koppers. G.P. (A) 347,672, 9.3.18, (B) 347,673, 20.6.18, (C) 347,674, 20.6.18, and (D) 347,675, 7.1.19.

(A) SEVERAL separate intermittent kilns are so arranged that cars carrying the goods to be burned can be passed into them from a preheating chamber, and after the firing is completed transferred to a cooling chamber. For each preheating chamber there are two cooling chambers, in order that the goods may be cooled sufficiently slowly. The firing chamber is divided into two compartments by a longitudinal partition; one compartment is heated by gas and air on the down-draught principle, and the hot gases pass through openings in the partition and then upwards through the other compartment to the regenerators. On changing the dampers in the regenerators the direction of the gases is reversed. (B) The bricks or other ware are burned on cars in a twin kiln, to which cold air and gas are first admitted direct, whilst the waste gases are passed through a regenerator. Afterwards, first the air only and then both air and gas are preheated regeneratively. The cooling is effected and controlled by shutting off the gas and admitting air through the regenerator last heated by waste gases, so that this air is strongly heated before it comes in contact with the goods, and cools them gradually. The air is then passed into the regenerator of another kiln. When one regenerator can no longer supply air at a temperature suitable for cooling the goods it is replaced by another regenerator, so that the cooling is effected at any desired rate without the goods being in contact with cold air. (C) In the plant described under (A) the regenerators are placed parallel to and alongside the burning chambers and are connected with the latter at the top. The gas to be preheated thus flows upward through the regenerator, then downward through one compartment of the burning chamber, upward through the other, and finally downwards through the regenerator on the other side. (D) The construction of the kiln is modified so as to convert it from an intermittent to a continuous tunnel kiln, and regenerators are provided in the cooling zone at each side of the kiln, so as alternately to preheat the cold air required for combustion and withdraw heat from the cooling goods. These regenerators prevent the hot goods from coming in contact with cold air, and the goods are cooled to such a degree by the time they reach the exit end of the kiln that they can pass out without risk of damage.—A. B. S.

Ceramic wares; Burning —— *and apparatus therefor. Burning ceramic wares.* T. G. McDougal, Assr. to Champion Ignition Co. U.S.P. (A) 1,416,726 and (B) 1,416,727, 23.5.22. Appl., 18 and 28.7.21.

(A) THE goods are passed continuously through a kiln having a preheating zone, a high-temperature zone, and a cooling zone, and are maintained exposed to radiation from the under surface of the roof of the kiln in the high-temperature zone sufficiently long to ensure thorough burning. The under surface of the roof is intensely heated by combustion in the space between it and the goods. (B) A continuous kiln has a thin highly refractory carrier forming the support for the ware, and supporting means on which the carrier travels through the kiln, the space between these supports and the lower side of the carrier being filled with heat-insulating material. The supporting means include a highly refractory element projecting through the floor of the kiln on which the carrier rests directly and with reference to which it is movable.—H. S. H.

Enamel; Process of removing —— *from enamelled metal articles.* W. E. Patch. U.S.P. 1,416,865, 23.5.22. Appl., 28.7.21.

THE enamel is removed by heating the ware in a closed oven to a temperature above the original baking temperature.—H. S. H.

Glass; Apparatus for feeding molten ——. F O'Neill. E.P. 179,977, 12.1 and 26.5.21.

Pug mills [*for clay mixtures*]. T. C. Fawcett, Ltd., J. W. Bottomley, and D. L. Fawcett. E.P. 180,035, 16.2.21.

IX.—BUILDING MATERIALS.

PATENTS.

Wood and the like; Protectively treating ——. *Protectively treating materials.* A. Arent, Assr. to A. Arent Laboratories, Inc. U.S.P. (A) 1,418,609 and (B) 1,418,610, 6.6.22. Appl., 14.11.19 and 9.6.20.

(A) WOODY materials are treated with a tarry solution containing a toxic and fire-retarding metal compound which is capable of hydrolysis to yield a compound of the metal insoluble in water. (B) Material is treated with a solution of antimony trichloride in benzene.—A. J. H.

Wood; Preservation of ——. *Impregnating wood* [*with oil*]. Ostpreussische Imprägnierwerke G.m.b.H. G.P. (A) 347,631, 21.5.14, and (B) 347,632, 1.9.15. Addns. to 345,704 (J., 1922, 296 A).

(A) Wood, such as pine, oak, and beech, which does not readily absorb liquid material, is subjected to a high vacuum before steeping in tar oil in the process described in the chief patent. For example, pine wood is maintained for 1 hr. under vacuum in a suitable vessel, and hot oil is admitted into the vessel while still under vacuum. After increasing the pressure to normal, the residual oil is removed, and the wood is treated with steam for ½ hr. at 2 atm. pressure, then with hot oil at 10 atm., and is finally subjected to a high vacuum for 1 hr. (B) Wood is impregnated with oil by treatment with oil vapour or atomised oil mixed with steam or air which is charged under pressure into a vessel containing the wood.—L. A. C.

[*Magnesium oxychloride*] *material; Process for manufacturing* —— *suitable for wall covering, putty, or the like.* K. Wolf, Assr. to Elektro-Osmose A.-G. U.S.P. 1,418,896, 6.6.22. Appl., 1.8.21.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ores; Sintering of ——. K. Endell. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1921, **3**, 37—43. Chem. Zentr., 1922, **93**, II., 1164.

To determine the sintering temperature of iron ores, the physical properties of five ores were examined after grinding them to pass through a sieve of 4900 holes per sq. cm. and heating test portions for 2 hrs. at 600°, 800°, 900°, and 1100° C. Density determinations showed that only limonite that contained considerable quantities of gels underwent any appreciable shrinkage and diminution of density. Direct observation of the sintering process by means of the "heating microscope" (*cf.* J., 1921, 394 A) gave the best results with partly colloidal ores, but was useless with others, while measurements of the contraction and porosity as applied to ceramic ware, were generally applicable, as immediately sintering commenced a sharp change was noticed in these properties. The commencement of the reaction between ferric oxide, silica, and lime was determined by solubility measurements; calcium ferrite begins to form, in the absence of silica, at 600° C.; when the latter is present, however, it appears to have a greater affinity for lime than has ferric oxide.—A. R. P.

Pig iron; Comparison of shaft and open top furnaces in the manufacture of —— *electrically from iron ore.* R. C. Gosrow. Trans. Amer. Electrochem. Soc., 1922, 63—74. [Advance copy.]

The principal disadvantages of the stack type of furnace are that the stacks may freeze up; the charge is subject to "hang-ups" and slips and segregation of the constituents; the pressure at the base of a stack crushes the fuel and interferes with the conductance; the charge is subject to bridging; no direct indication of the conditions inside the furnace is obtained. The contention that reduction is accelerated by the use of stacks is not proved. In the open-top furnace there is greater freedom of working and more accurate control. The charge travels a shorter distance, and the feed is through an overhung trolley provided with a hopper and spout. Continuous small charges are properly placed and distributed and no packing occurs. The gases leave the top of the furnace at low pressure, the combustibles burning with a short flame. The rectangular shape of furnace seems better than the circular for smelting, the heat being concentrated at or near the centre. In the open-top furnace the refractories last longer, and with proper feeding of the charge the loss of carbon is small. Open-top furnaces of 7000—10,000 kw. capacity are advocated. A comparison of carbon and graphite electrodes shows several advantages in favour of the latter. The average production cost per ton of iron is estimated on 1920 conditions as $39·66 for a plant with a capacity of 20,000 tons per year.—T. H. Bu.

Cast iron; Carburisation in the manufacture of synthetic ——. C. E. Williams and C. E. Sims. Trans. Amer. Electrochem. Soc., 1922, 157—176. [Advance copy.]

The carburising action of different forms of carbon increases with the density of the carbon and decreases as the ash content increases. Graphite gave the best results of all forms tried. The presence of slag decreases the rate of carburisation, the action being more effective as the acidity of the slag increases. Lime slags counteract the deleterious effect of high ash content. Silicon carbide in the inexpensive form of firesand is an excellent medium for adding both carbon and silicon to iron, but is generally used with coke to prevent the introduction of too high a percentage of silicon. Silicon and phosphorus have no effect on the rate or degree of carburisation, but may slightly decrease the total carbon content of the pig iron. Manganese increases the rate and degree of carburisation, but the effect is small for ordinary contents of manganese in iron. Sulphur probably decreases the rate and degree of carburisation. No noticeable effect on carburisation was observed on increasing the temperature from 1350° to 1450° C. —T. H. Bu.

Carbon in metals; Diffusion of —— *and mixed crystals of iron.* G. Tammann and K. Schönert. Stahl u. Eisen, 1922, **42**, 654—659.

Curves indicating the depths of the cementitic, pearlitic, and hypo-eutectoid layers when iron is carburised for 2 hrs. at different temperatures in a mixture of hydrogen and hexane vapour were found to be continuous. The coefficient of diffusion of carbon in iron as determined by different observers varies considerably and is dependent on factors not brought out in the analysis of the iron. The author attributes the differences to the influence of thin films of material between the crystallites of iron. On dissolving iron these intercrystalline films are destroyed, but in the case of cadmium and zinc the network of intercrystalline material may be isolated. The addition to iron of molybdenum, tungsten, nickel, cobalt, and manganese first increases and afterwards diminishes the depth of penetration of carbon; vanadium and antimony have no appreciable effect, and silicon and aluminium diminish the penetration of carbon. —T. H. Bu.

[Steel] furnace practice; British Siemens ——. F. Clements. Iron and Steel Inst., May, 1922. [Advance proof.]

THE balance of the chemical operations in a 60-ton Siemens furnace hearth was investigated, a notable feature being the relatively large extent to which carbon, silicon, phosphorus, and manganese are eliminated during the melting period. The heat balance was deduced from the chemical balance. The overall thermal efficiency amounts to 16·98%. The heat losses due to radiation from bath and port ends (44·2%), from regenerators (15·5%), and from flues (4·1%), and heat lost with the gases to the chimney (36·2%), were estimated, and the heat distribution throughout the system was determined for a selected half hour during the working period of a heat. A higher average temperature in the furnace hearth is desirable and this will be best attained by reducing the quantity of air admitted. The efficiency of the system of regeneration is critically discussed. The mean temperature variation in the chequers should only be about 100° C. The deductions made are confirmed by the data obtained from detailed schedules of British Siemens furnace practice. A design for a 100-ton furnace is suggested. The usual positions of gas and air uptakes are reversed. The gas reverse valves are as near the regenerators as possible and shut off the supply to the furnace while reversal takes place. The air reverse valves are water-sealed. A strong case may be made out for automatic reversal. The fuel consumption used in the calculations was 3 cwt. per ton of steel, but if radiant heat losses were prevented as suggested it is probable that the consumption would not be greater than 2 cwt. per ton of metal.—T. H. Bu.

Martin [open-hearth steel] process; Influence of the difference in height of, and distance between, the producer and furnace in the ——. E. Maurer and R. Schrödter. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1921, **3**, 21—36. Chem. Zentr., 1922, **93**, II., 1165.

A DECREASE in gas pressure between the producer and the furnace is avoided and the lowest pressure obtained in the producer if the gas-mains are of uniform cross-section and have no bends and the producer is only sufficiently high to avoid ground water and transport difficulties. Except for the effect of the additional friction, the length of the mains has no influence on the pressure, if they are straight, but to overcome any trouble likely to be caused by occasional pressure changes the furnace should be provided with a pressure-equalising chamber. The heat losses in the mains may be reduced by reducing the surface in contact with the gas, *e.g.*, by shortening the mains, or by covering them with a good heat-insulating material, but heat losses caused by settling of dust and soot, chiefly behind the dampers and in places where the cross-section or direction of the mains change, are unavoidable and are influenced by the nature of the coal. The energy content and significance of the physical and chemical properties of producer gas for regenerative heating are discussed.—A. R. P.

Austenitic steel; Arrangement of the iron atoms in ——. F. Wever. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1921, **3**, 45—56. Chem. Zentr., 1922, **93**, II., 1357.

THE X-ray spectrum of α-iron shows it to possess a space-centred cubic lattice, the side of the elementary cube being $2·85 \times 10^{-8}$ cm., while the γ-iron in homogeneous austenite has a cubical face-centred lattice, the length of the edge of the elementary unit of which varies between $3·56 \times 10^{-8}$ and $3·60 \times 10^{-8}$ cm., according to the nature and quantity of the alloying elements in the steel. Cooling in liquid air causes the austenite to be transformed partially into martensite with simultaneous diminution in the grain-size of the remaining γ-iron. Martensite contains α-iron, and the cause of austenitic steel becoming magnetic on cold deformation is shown to be the partial transformation of γ-iron into α-iron, the grain-size being probably less than 10^{-6} cm. The transformation of a steel containing 1·9% C and 2·1% Mn into troostite by annealing above 300° C. is due to the alteration of the γ-lattice into the α-lattice in the very fine-grained metal.—A. R. P.

Case-carburising; Selective ——. W. P. Wood and O. W. McMullan. Chem. and Met. Eng., 1922, **26**, 1077—1080.

THE protective action against case carburisation of a large number of non-metallic coatings was tried. The protective coatings consisted chiefly of a solution of sodium silicate mixed with clay, flint, asbestos, etc. A mixture of powdered asbestos and sodium silicate was found to give the best results, and after treatment may be removed by quenching in water, or by immersion in molten sodium hydroxide. The use of non-metallic protective coatings is not so generally applicable as an electrolytic deposit of copper. A deposit of copper by simple immersion, owing to its porosity, does not afford satisfactory protection against case-hardening.—C. A .K.

Steel; Effect of sulphur on rivet ——. E. E. Thum. Chem. and Met. Eng., 1922, **26**, 1019—1024.

THE author gives a résumé of a preliminary report of a joint committee of the American Society for Testing Materials and the U.S. Bureau of Standards on the effects of phosphorus and sulphur in steel. Steels containing about 0·11% C, 0·43% Mn, 0·01% P, and from 0·028 to 0·17% S were made into rivets and the latter were subjected to the usual forge and mechanical tests. The presence of sulphur up to 0·10% did not affect the hot or cold shortness and had no appreciable influence on the hardness. The tensile strength was decreased 200 lb. per sq. in. for each additional 0·01% S up to 0·10%. The maximum sulphur content now allowed in structural steel rivets (0·045%) is at least 0·01% below the point at which sulphur will prove harmful to the strength of a well-made rivet steel.—C. A. K.

Slag; Estimation of —— *in steel.* F. Wüst and N. Kirpach. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1920, **1**, 31—38. Chem. Zentr., 1922, **93**, II., 1070—1071.

A SOLUTION of bromine in aqueous potassium bromide was found to be the most efficient solvent for the iron in the determination of slag in steel, but the addition of oxalic acid to prevent the precipitation of basic salts caused solution of a portion of the silica, thus yielding low results. The method adopted was as follows: Steel filings (5 g.) were heated to 70°—80° C. for 4 hrs., with intermittent shaking, with 200 c.c. of a solution of 200 g. of bromine and 400 g. of potassium bromide in 1 l. of water. The solution was filtered and the residue, after washing with a solution containing 100 c.c. of water, 5 c.c. of sulphuric acid, and 1 g. of potassium bichromate, was dried, ignited, and weighed. Application of the method to the various structural constituents of steel showed that iron carbide, phosphide, and sulphide, and manganese in the amounts usually present dissolve under these conditions; nickel is partially oxidised. The presence of carbon, silicon, manganese, and chromium causes erroneous results, and needles of iron nitride are undissolved. The method is thus not applicable in all cases.—L. A. C.

Steels; Magnetic researches of nitrogenised ——. K. Kido. Sci. Rep. Tohoku Imp. Univ., 1922, **10**, 471—478.

Ten samples of steel containing from 0·084 to 3·02% of carbon were pulverised and then nitrogenised by heating in a current of dry ammonia gas at 650° C. for periods varying from 5 mins. to 15 hrs. After treatment the surface of the steel varied in colour from silver grey to dark grey, according to the duration of nitrogenation. The samples were then submitted to magnetic analysis. It was observed from the change of intensity of magnetisation with temperature that four transformations were possible at 250°, 350°, 470° and 620° C., respectively, the actual number of these transformations taking place in any given sample depending upon the composition. The magnetic transformation at 250° C. is due to the compound, Fe_2N, that at 470° C. to $Fe_{12}N$, whilst the transformations at 350° C. and 620° C. are attributed to two double carbides of iron and nitrogen termed α and β, respectively. On heating to 700° C. the nitrides of iron are rapidly decomposed into nitrogen and ferrite, the gaseous nitrogen escaping.—J. B. F.

Brazed joints; Dip-brazing with 80:20 *brass and the heat-treatment of* ——. E. V. Schaal. Chem. and Met. Eng., 1922, **26**, 1121—1125.

Preheating to a dull red heat just before brazing is desirable, but a higher temperature or continued heating should be avoided on account of oxidation of the surfaces to be brazed. The parts to be brazed should be coated with a paste made of borax and boric acid to prevent oxidation during preheating. Borax gives the best joints when brazing with 80:20 brass, but should be used in conjunction with a cooling flux, preferably of boric acid, in order to prevent surface oxidation. The proper brazing temperature is 1850° F. (1000° C.). The best joints are obtained when the surfaces to be brazed are fastened close together without the use of shims or spacers. The strength in pure tension of joints made with carbon steel untreated is approximately equal to the strength of the brass in tension; that of nickel steel joints heat-treated is nearly twice the strength of the brass. The strength of the joints in pure shear is also approximately equal to the tensile strength of the brass. Nickel steel joints tested in shear give approximately the same results as carbon steel joints. Heat treatment of brazed parts was found to deteriorate certain types of joints brazed with 80:20 brass, and no explanation of this could be found. Metallographic study of brazed joints reveals an intermediate constituent between the brass and the steel, which serves to hold the brass and steel together in the joint.

Iron and steel [galvanised] sheets; Method of determining the spelter coating on ——. D. M. Strickland. Amer. Soc. for Testing Materials, June, 1922. [Advance copy.] 6 pp.

A method, which may be used as a field method, of determining the weight of zinc on galvanised articles depends on the increase in temperature of the solution when the zinc coating is dissolved in a known quantity of hydrochloric acid. The volume of acid used (100—300 c.c.) regulates the conversion factor, *i.e.*, the value in grams for each 0·1° C. increase in temperature. Solution of the zinc is so rapid that the maximum temperature of the solution is reached in 30—40 secs., consequently radiation does not interfere with the accuracy of determination. Addition of antimony trichloride to the acid is not necessary, as the base metal may be attacked slightly without appreciable error. The apparatus required is simple and consists only of a glass container and a sensitive short-range thermometer.—C. A. K.

Copper-zinc alloys; Cold-rolling and annealing of ——. F. Körber and P. J. H. Wieland. Mitt. Kaiser Wilhelm-Inst. Eisenforsch. Düsseldorf, 1921, **3**, 57—87. Chem. Zentr., 1922, **93**, II., 1166—1167.

The effect of cold-rolling and annealing on the mechanical properties of copper-zinc alloys containing 28, 37, and 40% Zn has been studied. After cold-rolling all three alloys showed an increase in hardness, tensile strength, and elastic limit and a decrease in ductility and resistance to impact, to an extent depending directly on the amount of work done in the rolling. The tensile strength increased proportionally to the degree of rolling, and the ductility was especially decreased after rolling to reduce the thickness 30—50%, while the Brinell and scleroscope hardness increased rapidly at first, then more slowly, and the scratching hardness was unaffected. The relative alteration in tensile strength and hardness decreased with an increase in the zinc content of the alloys. The direction of rolling has a great influence on the ductility and resistance to shock, the metal being much more brittle perpendicular to this direction than parallel with it. Annealing at 200° C. improves the elastic and tensile properties of the 28% and 37% Zn alloys after severe rolling, but has the reverse effect on the 40% Zn alloy. Between 250° and 400° C. the tensile strength and elastic limit decrease rapidly and above 450° C. there is still a slight decrease. The test-pieces that had the most severe rolling had the highest tensile strength after annealing, and even after the most complete annealing the effect of the previous cold-rolling was noticeable. A fall in tensile strength on annealing corresponded with increase in ductility and a relatively greater decrease in hardness and brittleness. There was no change in the structure of the metal after annealing at 200° C., but at higher temperatures recrystallisation, characterised by the disappearance of slip bands and grain boundaries, commenced. The temperature at which this change occurred was lower the greater the degree of rolling undergone by the alloy, and was below that at which any change in the mechanical properties took place.

Brass; Physical properties of cartridge ——. C. Upthegrove and W. C. Harbert. Trans. Amer. Inst. Min. and Met., June, 1922. Min. and Met., May, 1922. [Advance copy.] 10 pp.

Cast brass containing approximately 68·42% Cu, 31·53% Zn, 0·03% Pb, and 0·02% Fe, was annealed and reduced in area, and then annealed at different temperatures (570°, 650°, and 750° C.) previous to the final reduction. The hardness was found to be influenced by both the temperature of annealing and the degree of reduction. Differences in hardness due to reduction disappeared when the metal was annealed at 600°—650° C., and also when the degree of reduction was increased. When annealed at 650° C. or above, after reduction in area by rolling, the hardness, tensile strength, and elongation were independent of the anneal, previous to rolling.—C. A. K.

[*Brasses, bronzes, and white metals;*] *Rapid electro-analysis* [*of* ——]. Kling and Lassieur. Ann. Chim. Analyt., 1922, **4**, 171—177.

Suitable electrolytes from which to deposit copper, lead, zinc, tin, and antimony by rapid electrolysis are given, and the following methods for the analysis of alloys containing these metals are recommended. *Analysis of brass.* 1 g. is dissolved in 5 c.c. of nitric acid (sp. gr. 1·3), the solution diluted to 85 c.c., and electrolysed for 20 mins. with 5 amp., using a rotating silver cathode and an iridio-platinum anode; copper is deposited on the former and lead peroxide on the latter. The residual liquid is boiled with 5 g. of sodium hypophosphite, and 15 c.c. of hydrochloric acid is added, a little at a time; boiling is continued for 10 mins. to remove completely the nitric acid. Caustic soda solution is added till the precipitate first formed just re-dissolves, then 20 c.c. of ammonia, and the cold liquid is electrolysed with 5 amp. for 20 mins., using the coppered cathode previously obtained. The zinc deposit is re-dissolved by spraying the washed cathode with 10 c.c. of 25% sulphuric acid, the solution is treated with caustic soda till the precipitate re-dissolves, then with an excess of 5 c.c. of acetic acid, and electrolysed as before, the zinc deposit being weighed this time. *Analysis of bronze.* 1 g. of alloy is dissolved in nitric acid containing 3 g. of crystallised aluminium nitrate, the solution is evaporated to dryness, and the residue heated for some time at 110° C., then digested with warm water and a little nitric acid. After addition of 2 g. of sodium nitrate the liquor is electrolysed as described above for copper and lead. The spent electrolyte is treated with 20 c.c. of strong hydrochloric acid, 4 g. of hydroxylamine hydrochloride, and 10 g. of ammonium oxalate, and electrolysed for 15 mins. with 5 amp. to deposit tin. *Analysis of white metal* (copper, lead, tin, antimony alloys). 1 g. is dissolved in hydrochloric acid and potassium chlorate, the solution is diluted to 100 c.c., made neutral to methyl orange with caustic soda, treated with 4—5 g. of tartaric acid, cooled, and transferred to a waxed conical flask. 10 c.c. of hydrofluoric acid is added and, after 30 min., 10 g. of sodium acetate crystals. The solution is diluted to 300 c.c. and saturated with hydrogen sulphide, and the precipitated lead, antimony, and copper sulphides are collected, washed, and digested with 80 c.c. of sodium sulphide solution (sp. gr. 1·14). The solution is filtered, the filtrate diluted to 150 c.c., treated with 4 g. of potassium cyanide, and electrolysed for 20 min. with a current of 3—4 amp. to deposit the antimony. The insoluble sulphides are dissolved in nitric acid, and the solution electrolysed for copper and lead as described above. The hydrofluoric acid solution containing the tin is treated with 10—15 g. of boric acid, transferred to an unwaxed beaker and boiled to expel hydrogen sulphide. The separated tin sulphide is dissolved, without filtering, by addition of hydrogen peroxide, the solution is cooled, treated with 20 c.c. of hydrochloric acid and 4 g. of hydroxylamine hydrochloride, and electrolysed for tin.—A. R. P.

Manganese-bronze; Occurrence of blue constituent in high-strength ——. E. H. Dix, jun. Trans. Amer. Inst. Min. Met. Eng., May, 1922. [Advance copy.] 16 pages.

In the manufacture of manganese-bronze, a third constituent, having a characteristic clear blue colour, appears in the α-β complex when sufficient hardening elements (aluminium, tin, iron, manganese) are added to produce a bronze of high tensile strength. The separation of this constituent is strongly influenced by the presence of iron, and it is precipitated from a copper-rich solid solution by the addition of zinc; it is therefore probably a solid solution of iron and copper, possibly containing also some tin, aluminium, or manganese. In the microstructure of manganese-bronzes this constituent appears, in unetched specimens, to be of a deeper blue colour than either the δ-constituent of the copper-tin series or the γ-constituent of the copper-zinc series, but the latter is rapidly dissolved by ammoniacal hydrogen peroxide, whereas the new constituent is hardly attacked. The presence of this constituent in reasonable amounts does not cause brittleness, nor does it reduce the elongation or tensile strength, although it is much harder than the α-β matrix. It cannot be dissolved by annealing for 8 hrs. at 850° C., followed by quenching or slow cooling.—A. R. P.

Nickel and monel [metal] wires; Some electrical properties of ——. M. A. Hunter, F. M. Sebast, and A. Jones. Trans. Amer. Inst. Min. and Met. Eng., June, 1922. Min. and Met., May, 1922. [Advance copy.] 6 pp.

Two samples of nickel wire obtained by the direct rolling of electrolytic nickel without melting the metal had specific resistance 7·55 and 7·60 respectively. Metal which had been melted and subsequently drawn into wire in no case gave so low a value. The addition of 1% of cobalt, iron, or manganese raised the specific resistance to 8·38, 8·82, and 9·41 for the respective elements. In order to obtain a nickel wire with the highest possible temperature coefficient of electrical resistance, the nickel must be the finest available, the addition of manganese must be as small as is compatible with good forging qualities, and the molten metal should be exposed to the effect of the furnace gases for as short a period as possible. The values for the specific resistance (ohms per mil.-ft.) at 20° C. of commercial metals examined are: Nickel grade A 64, grade C 84, grade D 117; monel metal 268.

—C. A. K.

Alloys of aluminium and zinc. T. Hemmi. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 511—524.

The author studied the equilibrium diagram of aluminium-zinc alloys, especially of alloys rich in aluminium. Thermal and microscopical examination of the alloys rich in aluminium gave no decisive data, but measurement of the electrical resistance of quenched specimens revealed fairly well the field boundaries in the diagram. Mechanical tests were made on chill and sand castings of alloys containing up to 50% Zn. Aluminium dissolves zinc up to a concentration of 30% at ordinary temperature, forming a stable solid solution γ. The range 42—78[illegible] Zn is a solid solution δ, which is unstable below 256° C., and easily decomposes into two different phases, γ and α. A field of the mixture (γ+δ) exists between the regions of γ and δ above 256° C. When annealed below 256° C., the compound, Al_2Zn_3, which assumes a dendritic structure in casting, decomposes into a duplex structure of α and γ. The presence of silicon, contained in aluminium as an impurity, causes a series of arrests in cooling alloys containing up to 70% Zn. The results of the mechanical tests show that the upper limit for addition of zinc to pure aluminium for light castings is 25%, the limit being within the range of solid solution γ. The density and hardness increase linearly with the zinc content, some examples being as follows:

	Zinc %	Elastic limit, kg. per sq. mm.	Tensile strength, kg. per sq. mm.	Elong. on 50·8 mm. %	Red. of area %	Brinell hardness.	Sp. gr.
Chill cast	10·36	10·43	13·66	14	20·5	69	2·94
	19·42	16·59	23·40	6·5	11·8	81	3·09
	36·67	18·48	29·00	2·0	5·07	80	3·55
Sand cast	9·97	12·60	14·7	8·2	10·0	36	2·88
	19·53	17·37	19·86	1·8	3·7	61	3·07
	33·96	18·26	25·8	1·6	1·7	74	3·40

—K. K.

Aluminium; The hydrochloric acid test [for resistance to corrosion] for ——. F. Mylius. Z. Metallk., 1922, 14, 233—244.

The test is carried out by observing the time taken to reach the maximum temperature when a strip of the metal is placed in 20 c.c. of hydrochloric acid (containing exactly 100 g. HCl per l.) at 20° C. The increase in temperature divided by the time taken to reach the maximum is called the "reaction number" of the metal. The metal surface must be clean and should be scrubbed with soap and dried before carrying out a test; even after this treatment a different result is obtained in two successive tests on the same specimen, due to the surface covering being in a different physical state to the body of the metal. Cast or annealed metal has a higher reactivity than metal that has been cold-drawn or rolled. Commercial aluminium alloys may be divided into four classes, those, *e.g.*, aluminium free from iron, which have a reaction number lower than 4; those for which the number is between 4 and 10, *e.g.*, technically pure aluminium, aludur, and duralumin; those for which the reaction number is between 10 and 20, *e.g.*, alloys containing 1—3% of iron and silicon, and those with a number higher than 20. Electrolytic oxidation of aluminium in saturated boric acid and borax solutions and, more especially, in fused potassium nitrate, lowers the reactivity of the metal very considerably; thus a specimen treated by the latter method had a reaction number of only 0·01.—A. R. P.

Metals and alloys; Density determinations on —— at high temperatures. II. The systems copper-antimony, copper-zinc, and zinc-aluminium. K. Bornemann and F. Sauerwald. Z. Metallk., 1922, **14**, 254—258. (*Cf.* J., 1922, 421 A.)

The density and specific volume together with data on the contraction on cooling of alloys of the systems copper-antimony, copper-zinc, and zinc-aluminium have been determined and tabulated. The temperature coefficient of expansion of liquid alloys in the first-named system falls from the antimony end to a point corresponding to the compound, Cu_2Sb, after which it rises more sharply. In the copper-zinc system there is an inflexion in the curve at a point corresponding to the compound, Cu_2Zn_3. The specific volume of the alloys of zinc and aluminium in the liquid state may be calculated by the rule of mixtures.—A. R. P.

Aluminium alloys, especially duralumin; Analysis of ——. F. M. da Costa-Vet. Chem. Weekblad, 1922, **19**, 249—251.

Duralumin contains, besides aluminium, copper 3·5—4·5, manganese 0·5—1·0, and magnesium 0·5%. In precipitating iron, aluminium, and manganese in the usual way, care must be taken to keep the magnesium in solution; the precipitation is repeated, and filtration must be rapid each time. Some manganese left in solution is weighed with the magnesium as pyrophosphate, and afterwards estimated by re-dissolving the phosphates and titrating with permanganate. (*Cf.* J.C.S., July.) —S. I. L.

Binary alloys [of lead, tin, and bismuth]; Volume changes of ——. K. Gilbert. Z. Metallk., 1922, **14**, 245—253.

The coefficient of thermal expansion of tin-lead alloys remains constant with rising temperature up to about 170° C., then increases rapidly to a maximum at the melting point of the eutectic, and falls rapidly to a minimum at about 200° C., rising again to a second maximum, which is less than the first, between 220° and 230° C. corresponding with the melting of the excess of tin or lead over the eutectic ratio. In the tin-bismuth series the coefficient of expansion decreases steadily to a minimum at the melting point of the eutectic (139·8° C.), then increases a little, but almost immediately decreases very rapidly. Alloys in which tin is in excess have a negative coefficient above 100° C., *i.e.*, they expand on further heating. Tin-bismuth alloys undergo a contraction in volume when maintained at a constant temperature for any time. This contraction is greater and more rapid the higher the temperature, but it takes place even at room temperature. The same phenomenon is observed in the case of the tin-lead-bismuth eutectic. This alloy, on heating, has a constant coefficient of expansion up to 80° C., after which the coefficient falls to a minimum at 94·9° C., then rises to a maximum at 112·8° C., and again falls to a constant value somewhat higher than the first, at 140° C.—A. R. P.

Magnesium-cadmium alloys. L. Guillet. Rev. Mét., 1922, **19**, 359—365.

Magnesium and cadmium form a continuous series of solid solutions and one compound, CdMg, melting at 427° C. and soluble in all proportions in either metal. The solidus is very close to the liquidus and hence the alloys are very uniform in character, although at ordinary temperatures there are several different solid solutions characterised by different electrical conductivities and hardness. No change in the latter property is produced by quenching or by quenching and ageing at any temperature, and the magnesium-rich solid solutions are malleable either hot or cold, but alloys containing about 6—42% Mg are brittle at ordinary temperatures although they are capable of being forged at 300° C. Small quantities of cadmium increase the Brinell hardness of magnesium from 32 to 60—65.—A. R. P.

Non-ferrous metals; Gas absorption and oxidation of ——. B. Woyski and J. W. Broeck. Trans. Amer. Inst. Min. and Met. Eng., June, 1922. Min. and Met., May, 1922. [Advance copy.] 8 pp.

The discoloured fracture of a non-ferrous alloy, usually considered to be due to oxidation, is believed to be rather the result of a reducing atmosphere. Castings produced from a sealed Detroit arc furnace always showed a discoloured fracture, but a normal casting was obtained from a ventilated Detroit furnace, or from the Baily furnace, which is not air-tight. Discoloration has also been observed in bearings poured from open flame furnaces with decidedly reducing flames. Aluminium-bronze is very susceptible to gassing, but by using oxidising conditions in oil furnaces gassing can be prevented entirely. An oxidising condition in the furnace is less troublesome than a reducing atmosphere, provided that the metal is protected by a thin layer of mineral flux. The loss of metal is not appreciably greater and there is a saving in time and fuel. The one condition of success is that the metal must be stirred to bring the oxides in contact with the flux, because the specific gravity of some oxides is greater than that of the metal.—C. A. K.

Tungsten ores of Boulder County, Colo.; Treatment of the ——. [Analysis of ferrotungsten and tungsten powder.] J. P. Bonardi and J. C. Williams. Bull. 187, U.S. Bureau of Mines, 1921. 79 pp.

The tungsten ores of Boulder consist chiefly of fairly well crystallised ferberite in a quartzose gangue. The ore is crushed and concentrated on jigs and tables in the usual way, and the concentrates, if tin or other objectionable impurity is present, are treated electromagnetically for the production of a ferberite concentrate containing 65—70% WO_3. Full details and flow sheets of the methods used at different mines are given, as well as descriptions of the methods used in working up the concentrates into ferrotungsten, tungsten powder and tungstic acid. The ferrotungsten produced assays 70—80% W, <1%C, <0·5% Mn,

<1% Si, and not more than 1·1% S and P together. The following method is recommended for assaying ferrotungsten and tungsten powder, which should first be ground to pass a 200-mesh screen. 1 g. of the sample is fused for 5—7 mins. at 800° C. with 5 g. of sodium peroxide in a nickel crucible, the cold melt is leached with water, and the solution treated with an excess of hydrochloric acid and boiled. 40 c.c. of cinchonine solution (50 g. of alkaloid and 150 c.c. of hydrochloric acid in 2 l. of water) is added and, after standing over-night, the precipitate is collected on a filter, washed with weak cinchonine solution, ignited, treated with hydrofluoric and sulphuric acids, again ignited, and weighed as WO_3. Carbon is determined by combustion in oxygen, the evolved gases being passed through barium hydroxide solution and the barium carbonate produced weighed. The whole of the sulphur in the sample is evolved as hydrogen sulphide on treating it with hydrochloric acid; this gas is collected in cadmium chloride solution and the precipitate is titrated with iodine. Phosphorus is determined by fusing 1 g. with peroxide as for tungsten. The solution of the melt is partly neutralised with hydrochloric acid, the ferric hydroxide filtered off, the filtrate acidified with 30 c.c. of 40% acetic acid, treated with 2 c.c. of 5% uranium acetate solution, a slight excess of ammonia, and a further 2 c.c. of uranium acetate, and the precipitate is filtered off, washed with hot water, and dissolved, together with the ferric hydroxide precipitate, in 25 c.c. of strong nitric acid and 30 c.c. of water. The clear solution is nearly neutralised with 45 c.c. of ammonia (1:1) and treated with 50 c.c. of molybdate solution. After 15 mins. the precipitate is filtered off, washed with acid ammonium sulphate solution, dissolved in ammonia, the solution filtered, and the filtrate acidified with sulphuric acid and passed through a Jones "reductor." The reduced solution is titrated with permanganate; the iron factor multiplied by 0·0163 gives the phosphorus factor.
—A. R. P.

Metals; Acceleration of solution of —— in acids by reducible compounds. H. J. Prins. Proc. K. Acad. Wetensch., 1922, 23, 1449—1454.

The velocity of solution of a metal in an acid may be enhanced by the presence of a reducible substance. Nitrobenzene and benzaldehyde accelerate the rate of solution of iron, zinc, lead, tin, copper, nickel, aluminium, and silver in a large number of acids. In the presence of nitrobenzene the rate of solution is increased up to 1000 times. The increase in the action of the acid on the metal is accompanied frequently by an increased evolution of hydrogen. Benzaldehyde is selective in its action. Benzophenone retards the rate of solution of the metal and the rate of generation of hydrogen from zinc and acid.—W. E. G.

Metallic substances; Constitution of ——. C. A. Kraus. J. Amer. Chem. Soc., 1922, 44, 1216—1239.

Metals and intermetallic compounds are salt-like in character and in liquid ammonia solution the more electronegative metal functions as anion, and on electrolysis is deposited on the anode. The multiplicity of compounds derivable from a given pair of metals is explained by the fact that in their compounds the more electronegative elements form complex anions. The energy effect accompanying the formation of metallic compounds is of the same order of magnitude as that accompanying the formation of ordinary salts, and as in the case of salts, the energy change is the greater the more electronegative one element is with regard to the other. The property of "metallicity" is not an atomic one; it may be imparted to non-metallic elements by combination with other non-metallic elements and is due to the presence of uncombined negative electrons. The electrons which impart metallic properties to an element are those to which the chemical reactions of this element with other elements are due. The reaction between strongly electropositive and strongly electronegative elements or groups of elements consists essentially in a combination of the negative electrons of the electropositive constituent with the atoms of the electronegative constituent. (*Cf.* J.C.S., August.)
—J. F. S.

Patents.

Steel or iron work; Materials for and method of treating, or preserving —— against corrosion and rusting. G. H. Howse. E.P. 179,811, 2.5.21.

Iron or steel is coated with a mixture of an oxy-acid of phosphorus, *e.g.*, phosphoric acid, and chromium oxide or hydroxide, dissolved in a suitable solvent, *e.g.*, acetone, alcohol; oxide, hydroxide, or chromate of manganese, lead, or nickel may also be added. The metal may be painted subsequently. The process is intended to be applied where corrosion has already taken place, the active iron oxide being converted into an inactive condition by application of the mixture.—C. A. K.

Cast iron; Purifying —— and eliminating objectionable gases and oxides. J. R. Billings, Assr. to J. R. Billings Iron and Steel Co. U.S.P. 1,412,077, 11.4.22. Appl., 25.5.16. Renewed 25.8.21.

Reagents capable of eliminating hydrogen and phosphorus are added to the molten iron, and finely divided carbon is then introduced gradually into the body of the molten metal.—T. H. Bu.

[Iron] castings; Method of controlling the condition of [i.e., rendering malleable] ——. O. Sowers. U.S.P. 1,417,638, 30.5.22. Appl., 6.4.21.

An electric current is passed through the casting which is heated by resistance only, the electrodes or contact pieces being so shaped as to cause more current to pass through the thicker portions of the casting, thus obtaining uniform heating (for several hours) to a temperature near that at which combined carbon changes to temper and free carbon.—B. M. V.

Ferro-chromium alloys; Manufacture of ——. W. B. Ballantine. E.P. 179,992, 19.1.21.

High carbon ferro-chromium is subjected to the action of an oxidising blast while maintained well above its melting point in an electric furnace. The necessary flux is carried to the metal by means of the blast, which may impinge directly on, or at an angle to, the surface of the bath. The carbon content in a trial was reduced from 5·65% to 0·25% in 40 mins. when using an air blast at a pressure of 8 lb. per sq. in.—C. A. K.

Blast furnaces; Method of operating smelting and reducing furnaces, more particularly ——. H. Koppers. E.P. 156,765, 7.1.21. Conv., 23.10.18.

A portion of the hot gas evolved in the blast furnace is withdrawn from above the blast inlet level at a temperature of about 1400° C., and the whole or part of this gas is cooled to about 800° C. and then introduced again into the furnace at a somewhat higher level. The temperature zone in which carbon dioxide has an oxidising effect is thus eliminated, and a shorter shaft can be used, thus reducing the resistance of the charge and consequently reducing the power required for the blast.

The sensible heat taken from the withdrawn gas is utilised for preheating or drying the charge. —T. H. Bu.

Zinc; Method of extracting —— from lead-slags, zinc-retort residues, poor zinc ores or the like. Rheinisch-Nassauische Bergwerks- und Hütten-A.-G., and A. Spieker. E.P. 160,455, 17.2.21. Conv., 17.3.20.

The finely ground residues are briquetted with lime or silica in such a proportion that the resulting slag is either very basic or very acid and of a high melting point. The resulting briquettes are smelted in a shaft furnace, whereby the zinc is reduced and volatilised only when the briquettes reach the hottest zone, and a slag is obtained containing less than 0·5% Zn.—A. R. P.

Zinc ashes or zinc oxide containing chlorides; Method of working —— [for the recovery of zinc]. Oberschlesische Zinkhütten A.-G. G.P. 350,702, 14.4.21.

The ashes or other material containing zinc oxide and chloride are mixed intimately with calcined limestone or dolomite dust and water before reduction. The calcium chloride so formed is only decomposed at a very high temperature and does not interfere in the subsequent reduction.—A. R. P.

[Aluminium;] Process for the reduction of [—— from its] ores. C. A. Stevens, Assee. of C. G. Collins. E.P. 160,760, 14.2.21. Conv., 26.3.20.

The ore, ground to pass a 20- to 40-mesh screen, is mixed with about 5% of its weight of carbon, 3% of sodium chloride, and 2% of sawdust impregnated with alkali, and the mixture is heated in a closed furnace to about 1400° F. (760° C.). The sawdust may be replaced by oxalates.—A. R. P.

Chromium or alloys of chromium; Method for producing ——. Aktiebolaget Ferrolegeringar. E.P. 163,263, 28.4.21. Conv., 12.5.20. Addn. to 135,187 (J., 1921, 86 a).

At the end of the bessemerising process for the production of chromium alloys, the slag becomes relatively rich in chromium. This slag is retained in the furnace during the early part of the working of the following charge and when the removal of silicon has proceeded to the stage at which the content of chromium in the slag is at a minimum, the highly silicious, low-chromium slag is tapped off. The oxidation of silicon is then completed in the furnace, with the addition of basic materials if necessary, and the smaller quantity of high-chromium slag formed is used in the working of the following charge.—C. A. K.

Copper [nickel, and lead] ores; Treatment of oxidised ——. W. G. Perkins. E.P. 180,021, 14 and 21.2.21.

A magnetic product is obtained by heating the ore with sulphur or iron sulphide (pyrites) in a non-oxidising atmosphere, and is concentrated by magnetic separation. The ore is preferably heated in a reducing atmosphere before admixture with the pyrites.—C. A. K.

Slag; Process of granulating —— and separating moisture therefrom. T. Steen. E.P. 180,479, 23.3.21.

Slag, granulated by quenching in water, is spread in a thin layer over a floor of large area, and the water is drawn off rapidly, preferably by means of a suction apparatus. The hot slag may be allowed to dry naturally, or it may be dried by heat (*e.g.*, by the exhaust gases from a gas-engine) and then cooled rapidly by a current of air or water, this rapid cooling causing further granulation. —A. B. S.

Alloy. A. W. Randall. U.S.P. 1,417,348, 23.5.22. Appl., 29.11.20.

An alloy containing 80—87 (*e.g.*, 84)% Zn and 20—13 (*e.g.* 16)% Al.—C. A. K.

[Tungsten] alloy for contact bodies and ignition points. C. A. Laise. U.S.P. 1,418,081, 30.5.22. Appl., 2.5.21.

The alloy contains 87—97% W, 10—3% Mo, and a substantial amount of vanadium not exceeding 1%. —A. R. P.

Soldering composition. A. Traliot. U.S.P. 1,417,428, 23.5.22. Appl., 2.4.21.

A solder containing aluminium, sulphur, and a number of metals of low melting point.—C. A. K.

Ores and the like; Process for chlorinating —— in mechanical roasting furnaces. Metallbank und Metallurgische Ges. A.-G. G.P. 350,645, 10.4.14.

The heat necessary for the chlorination process is supplied by radiation from above to the upper chlorinating chamber, and the hot flue gases from this source of heat are led into the same chamber and pass out with the chlorinating gases. In this way the ore never comes in contact with hot surfaces, and is therefore not overheated, and the temperature of the top hearth of the furnace can be accurately controlled.—A. R. P.

Reducing gases; Process for the preparation of —— for metallurgical purposes. A/S. Norsk Staal. G.P. 350,647, 25.2.19. Conv., 4.9.15.

A fuel containing carbon monoxide is subjected, together with waste gases (containing carbon dioxide and/or steam) from metallurgical operations, to the action of a high-tension electric discharge, in a manner similar to that used in the combustion of nitrogen. The following reactions take place:—$C_mH_n + mCO_2 + 41{,}700m$ cals. $= 2mCO + n/2H_2$, and $C_mH_n + mH_2O + 31{,}000m$ cals. $= mCO + (m+n/2)H_2$.—A. R. P.

Burnt pyrites and the like; Process for removing zinc from ——. F. W. Neuhaus. G.P. 350,649, 20.11.20.

Desulphurised material, such as burnt pyrites, is heated to 1000°—1100° C. in an atmosphere of a reducing gas such as blast-furnace gas, whereby the zinc is reduced and volatilised, and the residue is obtained as an agglomerate of partially reduced iron, which may be smelted in the blast furnace. Addition of solid carbon is unnecessary.—A. R. P.

Iron and alloys of iron; Electrodeposition of metals upon ——. R. J. Fletcher, Assr. to Fletcher Electro Salvago Co., Ltd. U.S.P. 1,417,896, 30.5.22. Appl., 17.1.21.

See E.P. 162,391 of 1920; J., 1921, 436 a.

Copper-nickel matte; Treatment of ——. G. Haglund. E. P. 158,887, 7.2.21. Conv., 10.2.20.

See G.P. 343,079 of 1921; J., 1922, 379 a.

Lead; Refining of ——. H. Harris. U.S.P. 1,418,148, 30.5.22. Appl., 29.1.20.

See E.P. 142,398 of 1919; J., 1920, 456 a.

Aluminium alloy. H. C. Hall, Assr. to Rolls-Royce, Ltd. U.S.P. 1,418,303, 6.6.22. Appl., 18.2.21.

See E.P. 153,514 of 1920; J., 1921, 15 a.

Ores; Apparatus for grinding, classifying, and decanting ——. J. R. Broadley. U.S.P. 1,418,523, 6.6.22. Appl., 30.9.20.

See E.P. 154,434 of 1919; J., 1921, 70 a.

Patents.

Electric primary cells. L. Darimont. E.P. 180,120, 16.3.21.

In primary cells employing a zinc electrode immersed in an exciting solution of a chloride, such as sodium chloride, and a carbon electrode immersed in iron perchloride, powdered chalk or other anti-acid material is added to the former solution, and an agglutinant such as starch is added to retain the chalk in suspension. The chalk reacts with iron perchloride diffusing through the wall of the porous cell, and a semi-pervious layer is formed, which is prevented from becoming too thick by the addition of a mixture of chromic acid or chromium salts and hydrochloric acid to the depolarising fluid, to which sodium or potassium chloride is similarly added to regulate the osmotic pressure and precipitate hydroxides and oxides of iron, which would otherwise form insulating deposits on the carbon. To prevent creeping of iron perchloride on the wall of the porous vessel, that portion which is above the paste is made impervious by prolonged immersion in molten lead oleate or similar substance, with or without the addition of other metallic soaps, such as soaps of iron or manganese. The head of the carbon electrode is similarly treated. The bottom of the porous vessel is entirely or partially convex externally. The upper portion of the porous vessel is closed by wax, pitch, etc., through which passes a tube having a widened neck closed by a stopper provided with a slot or groove for the escape of gases. The zinc electrode need not be amalgamated. The cell is provided with a closing ring of cork or other compressible material.—J. S. G. T.

Dry batteries; Process for the preparation of —— with manganese dioxide-graphite electrodes. H. Riesenfeld. G.P. 350,248, 10.2.20.

The pressed electrodes of manganese dioxide and graphite are dipped into a colloidal solution so as to give them a coating of a colloidal material, which prevents the formation of cracks and the loss of small particles, and gives the cell a better conductivity and a smaller internal resistance, and, therefore, greater capacity.—A. R. P.

Electric cell. A.-G. Mix und Genest Telephon- und Telegraphen-Werke. G.P. 350,925, 1.10.20.

The cell is of the type in which zinc, carbon, and manganese dioxide are used, and the electrodes are separated by a semi-permeable diaphragm. An electrolyte of the usual kind is employed on the zinc side of the diaphragm, whilst on the other side a soluble substance with powerful oxidising properties, *e.g.*, a hypochlorite, is used, for the purpose of intensifying the depolarising action of, and revivifying, the manganese dioxide.

Electric furnace. F. W. Sperr, jun., and H. J. Rose, Assrs. to The Koppers Co. U.S.P. 1,418,984, 6.6.22. Appl., 14.3.21.

A relatively long and narrow heating chamber is formed by means of a series of juxtaposed heating units. A testing tube placed inside the heating chamber is heated progressively by connecting the units in circuit from one end to the other.
—J. S. G. T.

Electric furnace. H. G. Weidenthal, Assr. to Westinghouse Electric and Mfg. Co. Reissue 15,378, 6.6.22, of U.S.P. 1,304,425, 20.5.19. Appl., 25.3.20.

XII.—FATS; OILS; WAXES.

Olive oils and the Villavecchia reaction. J. Prax. Ann. Falsif., 1922, **15**, 159—161.

The formation of a red coloration with Villavecchia's reagent by abnormal olive oils (*cf.* J., 1921, 778 A) is prevented by treatment with alcoholic ammonia, and this is now shown to be due to the action of the ammonia.—W. G.

Head oil of the sea animals of the family Delphinidæ. S. Nakatogawa and S. Kobayashi. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 158—168.

The authors have examined the jaw, head, and inner head oils of the following sea animals: "Ma-iruka" (*Delphinus longirostris*, Gray), "Kama-iruka" (*Lagenorhynchus acutus*, Gray), "Nezumi-iruka" (*Phocoena communis*, Less), "Sunameri" (*Neomeris phocoenoides*, Gray), "Nuribô," and "Gondô-kujira" (*Globiocephalus sieboldii*, Gray). The oils contained highly unsaturated fatty acids, as shown by the formation of polybromides, and notable proportions of lower fatty acids. The head oils and more especially the inner head oils (except *Neomeris* oil) contained more unsaponifiable matter than the jaw oils. The head and jaw oils were soluble in hot absolute alcohol, whereas the inner head oils were soluble in cold absolute alcohol. The solidifying points of the oils were far lower than those of other marine animal oils.—K. K.

Fatty oils; Mechanism of alkali refining of ——. S. Ueno. Kôgyô-Kwagaku Zasshi (J. Chem. Ind. Japan), 1922, **25**, 578—583.

Metallic and alkali soaps and oxidised acids are removed to a notable extent by alkali refining. Similar effects are observed on treating the oils with soap solution, but the action is slower. Substances acting as anti-catalysts in the hydrogenation of the oils are removed by using a very small quantity of alkali solution (about 2·5 c.c. of 20% sodium hydroxide solution for 50 g. of oil), and fish oils thus refined can be hardened smoothly, notwithstanding the oil has still an acid value of 3·2—10. Alkali refining is considered to be due to the adsorption of impurities by the emulsoid-like compounds formed by the addition of alkali to oils, whilst refining with acid-clay is ascribed to the adsorptive action of suspensoid-like compounds. Poisonous matters present in oils can easily be removed by alkali refining. In the hardening process, the hardened oil is electrically charged; the phenomenon is especially distinct in highly hardened samples.—K. K.

Vegetable oils; Decolorisation of ——. M. J. van Tussenbroek. Chem. Weekblad, 1922, 19, 266—267.

Generally Norit was found to have the best decolorising action on unwashed oils, and fuller's earth on oils washed free from acid. A carefully refined colourless sample of coconut oil, with an acid value of 0·08%, was coloured with 1% of aminoazobenzene, and heated to 90° C. for one hour with 1% of Norit, with the addition of quantities of "Ijsazijn" varying from 0·2—2·0%. The best results were obtained with 1·4—1·6% of "Ijsazijn." The efficiency of an adsorptive decolorising agent may be determined by tests with a substance easily soluble in oil and capable of being titrated, such as aniline or β-naphthol.—H. M.

Dihydroxystearic acid; Oxidation of ——. Y. Asahina and Y. Ishida. Yakugakuzasshi (J. Pharm. Soc. Japan), 1922, [481], 171—179.

Dihydroxystearic acid (504 g.) is easily oxidised to azelaic acid (202·5 g.) and pelargonic acid (130 g.), by treating with a mixture of sodium bichromate and sulphuric acid whilst introducing steam at 110°—120° C. By the same treatment, trihydroxystearic acid (480 g.) is oxidised to azelaic acid (89 g.) and œnanthylic acid (41·5 g.). (*Cf.* J.C.S., July.)—K. K.

Indian beeswax; Constants of ——. O. D. Roberts and H. T. Islip. Analyst, 1922, 47, 246—251.

Tables are given of the constants of 23 samples of honeycomb and wax collected under the supervision of District Officers in Bengal, Eastern Bengal, and Assam. The following are the minimum, maximum, and average values obtained respectively. Sp. gr. 0·9555, 0·9733, 0·9652; m.p. 60·4°, 66·4°, 61·4° C.; acid value, 3·7, 7·6, 5·8; ester value, 87·4, 96·0, 92·1; ratio of ester value to acid value, 12·2, 26·0, 16·7; iodine value, 4·5, 7·7, 5·6; Salamon and Seaber's test (J., 1915, 461), 52, 62, 57·6; hydrocarbons, 6·9, 12·9, 9·8%. The low acid values obtained are remarkable, being in many cases lower than 6, the figure hitherto accepted as the lowest representing unadulterated Indian beeswax. Both Weinwurm's test (Lewkowitsch, Chem. Technol. Anal. of Oils, Fats and Waxes, 1914 Ed., Vol. 2, 921) and Salamon and Seaber's test are shown to be untrustworthy. —H. C. R.

Iodine value of aliphatic and aromatic unsaturated compounds; Determination of the ——. D. Holde, P. Werner, I. Tacke, and C. Wilke. Chem. Umschau, 1922, 29, 185—188.

The determination of the iodine value is a valuable criterion of the purity of higher unsaturated fatty acids and their derivatives when other methods such as molecular weight determinations and melting points fail, and has been used by Holde and Wilke in the case of erucic acid (J., 1922, 260 a). In these instances the Hanus reagent is preferred (10 g. of iodine monobromide in 500 c.c. of glacial acetic acid), as it gives results in close agreement with Hübl's reagent, and is more easily prepared, more stable, and more rapid in action, standing for 15 mins. with about 50% excess of the reagent being sufficient to complete the reaction. Accurate results are also obtained with aromatic unsaturated compounds, *e.g.*, safrole, under similar conditions. Anomalous results are given by the Hübl-Waller solution and by Wijs' solution for both cholesterol and phytosterol, the former reagent giving abnormally low and the latter abnormally high results. With the original Hübl solution, however, consistent though slightly high results (73—77 compared with 65·7 theoretical) were obtained with cholesterol, but with phytosterol values varying from 41 to 76 were obtained according to the duration of the reaction and the excess of Hübl solution employed. With both alcohols Wijs' solution gave values of 135, that is approximately double the theoretical. A similar difference in the results with Waller's and Wijs' solutions has been observed with thick mineral lubricating oils and with naphthenic acids, which may indicate the presence of cholesterol derivatives in these natural products.—G. F. M.

Patents.

Oil and like extractor. K. F. Wilhelm. U.S.P. 1,418,503, 6.6.22. Appl., 11.11.13.

A double-walled hollow cylinder is supported on hollow shafts so that it can be rotated about a horizontal axis. Transverse filtering pipes which can be detached are arranged within the cylinder, and a discharge pipe carried along the outside of the cylinder communicates with the filtering pipes through apertures made in the cylinder wall, and also with the hollow shaft, so that liquid can be discharged during the rotation of the cylinder. Solvent can be introduced into the cylinder through one of the shafts and steam can be circulated through the space between the cylinder walls. A second discharge pipe is connected with the end wall of the cylinder near the circumference and affords communication between the cylinder and the hollow shaft, so that liquid can be drawn off from various altitudes within the cylinder.—H. C. R.

Oils and fats; Neutralisation of ——. E. R. Bolton and E. J. Lush, Assrs. to Technical Research Works, Ltd. U.S.P. 1,419,109, 6.6.22. Appl., 21.2.21.

See E.P. 159,587 of 1919; J., 1921, 310 a.

XIII.—PAINTS; PIGMENTS; VARNISHES RESINS.

Red lead; Volumetric estimation of lead dioxide in ——. A. Bonis. Ann. Falsif., 1922, 15, 157—159.

The following modified procedure for estimating lead peroxide by Diehl's method is advocated. 0·5 g. of the sample is macerated with 2·5 c.c. of nitric acid (sp. gr. 1·08) and the mixture is washed into a conical flask with 25 c.c. of a saturated solution of sodium acetate. To the suspension 10 c.c. of a 12% solution of potassium iodide in saturated sodium acetate is added, the whole is well shaken, and the iodine liberated is titrated with $N/10$ thiosulphate solution. If the sample of red lead contains iron oxide, instead of titrating the free iodine, an excess of the standard thiosulphate is added, and the whole is made up to 100 c.c. with the saturated sodium acetate solution. After filtering, an aliquot portion of the filtrate is titrated back with $N/10$ iodine solution.—W. G.

Whitewashes and aqueous lime paints; Investigation of ——. G. J. Fink. J. Ind. Eng. Chem., 1922, 14, 503—511.

Trials of 175 different aqueous paints prepared with milk of lime as basis were made, including exposure tests for 3 and 6 months respectively. Of the common ingredients of a non-binding nature added to the simple limewash, common salt proved of decided value, other inorganic substances, *e.g.*, sodium phosphate, fluoride, borate, and carbonate, whiting, calcium sulphate, asbestine, copperas, alum, or zinc oxide showing no effect or at most a doubtful improvement. Magnesium, calcium, and zinc chlorides proved of some slight value in enhancing durability. Of the binders or "siccatives," which comprised casein, glue, flour, sodium silicate, and soap, the first-named showed outstanding merit as an ingredient of limewash, the working qualities and durability on exposure being particularly marked when the composition also contained trisodium phosphate for accelerating the solution of the casein, and formaldehyde for rendering the casein film insoluble. Both glue and sodium silicate have a tendency to cause scaling of the film, but limewash containing both glue and trisodium phosphate gives satisfactory results in interior decoration, and if formaldehyde also be added, the dried film is resistant to soap and water. The benefit attendant on the use of drying oils as ingredients of whitewash is greatly discounted by their effect in diminishing the opacity of the lime pigment. —A. de W.

Varnishes; Testing ——. *III. Hardness tests.* H. Wolff. Farben-Zeit., 1922, **27**, 2555—2556.

An apparatus for testing the hardness of varnish films consists of a triangle formed by three wooden strips, the base of which is hinged to the face of a baseboard. At the apex of the triangle is fitted a blunt knife edge directed towards the face of the baseboard. Pressure is exerted on the knife edge by means of a small loaded dish set on the apex of the triangle directly over the knife edge and arranged to be counterpoised to zero load by a lever carrying a sliding weight and set at right angles into the hinged base of the triangle in a direction away from the apex. The varnished test plate is fixed to two strips which slide in guide rails fastened to the baseboard, and is moved at a definite rate, so that the film comes in contact with the knife edge. By means of a paper scale attached to the test-piece a number of "cuts" can be made at varying loads and compared. By substituting a strip of tinned iron in place of the knife edge and taking observations at loads slightly above zero, the progress of drying of a varnished surface can be observed by the adhesion or otherwise of the testing edge.—A. de W.

Phenol-aldehyde condensation products; Comparative examination of —— *as substitutes for shellac in spirit varnishes and polishes.* E. Fonrobert. Chem.-Zeit., 1922, **46**, 513—514.

Ten phenol-aldehyde condensation products from different sources were submitted to tests with a view to their evaluation as substitutes for shellac in spirit varnishes and polishes. The melting-points (incipient sintering to complete fusion) ranged from 40°—46° C. to 97°—105° C.; one sample, showing an incipient melting-point of 80° C., failed to melt completely and, moreover, was the only one not completely soluble in alcohol. The ash content in no case exceeded 0·6%. The acid values of eight samples ranged from 1·1 to 9·0, another sample showing a value of 42·6. Paleness of colour was in most cases accompanied by a strong odour of cresol, the samples possessing strong odours furthermore usually deepening in tint when the films from the alcohol solutions were maintained at 100° C. for 24 hrs. Only two of the samples were free from smell of cresol at ordinary temperatures, and some of them contained a proportion of cresol sufficient to produce unpleasant effects as a result of contact of the skin of the hand with the varnished surface. Elasticity of the film, due to the presence of free cresol, was only transient, as was shown by observation of the films after submission to a rapid ageing test (exposure at 100° C. for 24 hrs.). All the samples were much inferior to shellac in regard to hardness and elasticity. The films from the varnishes varied from a condition of sensitiveness to hand-warmth in the early stages, to brittleness after stoving at 100° C. for 24 hrs., two samples, however, giving films which were fairly elastic after stoving. Phenol-aldehyde condensation products must be regarded as poor substitutes for natural shellac.—A. de W.

Abietic acid and certain metal abietates. L. L. Steele. J. Amer. Chem. Soc., 1922, **44**, 1333—1341.

Abietic acid may readily be prepared by boiling white rosin with 98% acetic acid for 2 hrs. under a reflux condenser and then, after filtering the mixture, leaving it to cool overnight. The acid is best recrystallised from 98% acetic acid. The abietates of lead, manganese, cobalt, nickel, chromium, and iron were prepared by pouring a neutral solution of sodium abietate into an excess of an aqueous solution of one of the salts of the corresponding metal. (*Cf.* J.C.S., Aug.)—W. G.

Patents.

Carbon black, lampblack and hydrogen; Method of manufacturing ——. H. J. Masson, Assr. to J. M. Gerard. U.S.P. 1,418,385, 6.6.22. Appl.,17.7.20.

A substance containing carbon is decomposed by passing it through a body of molten catalytic material, the temperature of which is sufficiently high to decompose the substance into minute particles of carbon and hydrogen, the carbon thus formed being removed from the molten catalyst with sufficient rapidity to maintain the black colour and softness of the carbon produced.—A. de W.

Lampblack; Preparation of ——. W. K. Lewis, Assr. to The Goodyear Tire and Rubber Co. U.S.P. 1,418,811, 6.6.22. Appl., 13.8.18.

Imperfect combustion of natural gas for the production of lampblack is effected by burning the gas in the presence of approximately 15—20 vols. of combustion gas.—A. de W.

Phenol-aldehyde condensation products. Condensite Co. of America, Assees. of D. S. Kendall. E.P. 159,164, 17.11.20. Conv., 19.2.20.

A phenolic condensation product, permanently fusible below 218° C., is obtained by heating together in a closed digester at 200°—220° F. (93°—104° C.), a phenol and acetaldehyde or a polymer thereof in the presence of a quantity of an inorganic acid condensing agent, *e.g.*, hydrochloric or sulphuric acid, not exceeding 0·5% of the phenol used, until the acetaldehyde has substantially all reacted with the phenol. During the reaction external heating is stopped and a cooling medium applied to the digester to maintain the temperature within the specified limits. Excess of phenol and water are removed from the product, *e.g.*, by distillation, and the acid condensing agent is also removed, or neutralised and separated. The fusible resin thus obtained may be treated with methylene-containing substances, *e.g.*, hexamethylenetetramine, so as to form an infusible substance on the application of heat. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 18,258 of 1913; J., 1914, 841.)—A. de W.

Phenolic condensation product; Process of making a ——. D. S. Kendall, Assr. to Condensite Co. of America. U.S.P. 1,418,718, 6.6.22. Appl., 10.5.20.*

A liquid mixture of phenol, formaldehyde, and water containing dissolved hexamethylenetetramine in which the formaldehyde is present in sufficient quantity to react with the phenol to form a fusible resin, and the hexamethylenetetramine sufficient to react with the resin to form an infusible product, is

heated to cause reactions between the phenol, formaldehyde, and hexamethylenetetramine and obtain a fusible resin containing hexamethylenetetramine in solution but substantially no uncombined formaldehyde.—A. de W.

Printing inks; Process for the manufacture of black ——. Rütgerswerke A.-G., and H. Teichmann. E.P. 166,117, 15.6.21. Conv., 8.7.20.

Solutions obtained as described in E.P. 131,588 and 160,467 (*cf.* G.P. 320,056; J., 1920, 622 A) by treating coal and other organic material, such as wood, peat, straw, cotton, and the like, with tar oils at, *e.g.*, 300° C., or resinous, bituminous residues obtained in distilling such solutions, are suitable for use in the manufacture of printing inks. For example, 58 pts. of coal extract resin oil produced as described in E.P. 131,588, is ground with 12 pts. of lampblack and 30 pts of straw extract oil. Other materials, such as petroleum pitch, asphalt, coumarone resin, or oils, such as boiled linseed oil, resin oils, or the like, as well as colouring matter to modify the shade, may also be added.—L. A. C.

Paints, varnishes, etc.; Removal of ——. W. Tiddy, Assr. to Rainey-Wood Coke Co. U.S.P. 1,417,955, 30.5.22. Appl., 19.5.21.

Heavy coal-tar bases, substantially free from pyridine, are used to remove paints, varnishes, etc.
—C. I.

Preservation of wood, pasteboard, masonry, leather, sheet iron, etc.; Coating for the ——. E. Reck, Assr. to Freeses Patent Eisenchutz und Schraubenwellenbekleidung für Schiffe G.m.b.H. U.S.P. 1,418,172, 30.5.22. Appl., 6.1.21.

See E.P. 153,293 of 1920; J., 1922, 65 A.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; State of —— *in its solutions.* P. Bary. Caoutchouc et Gutta-Percha, 1922, **19**, 11393—11395.

Einstein's formula for the viscosity of suspensions if applied to the viscosity of very dilute solutions of rubber, and Hatschek's formula for emulsoids at slightly higher concentrations, both indicate that rubber, when dissolved in benzene, enters into combination with more than 100 times its weight of the solvent. Solutions of rubber in benzene containing above 1% of the dry material are regarded as more or less fluid jellies. Maximum swelling of the rubber occurs at a concentration of about 0·3%. Below this concentration the jelly probably disintegrates in the solvent with simultaneous reduction in the degree of swelling of the rubber. The position of maximum swelling is influenced by the quality of the rubber and also by the nature of the solvent.—D. F. T.

Patents.

Vulcanisation of rubber employing amines and open-chain aldehydes and similar substances and products obtained thereby. S. M. Cadwell, Assr. to Naugatuck Chemical Co. U.S.P. 1,417,970, 30.5.22. Appl., 28.5.21.

Rubber is vulcanised after being mixed with a vulcanising agent and a product obtained by the interaction of an aliphatic aldehyde and an amine.
—D. F. T.

Rubber; Treatment of ——. W. A. Beatty. U.S.P. 1,418,271, 6.6.22. Appl., 6.6.18.

A base for chewing gum is prepared from raw rubber by treating the latter with a solvent for the nitrogenous substances present therein, separating the resulting solution, and subjecting the residual rubber to the action of heat and an inert gas to remove volatile substances.

Accelerator [*of vulcanisation*]. *Vulcanising rubber.* R. B. Naylor, Assr. to Fisk Rubber Co. U.S.P. (A) 1,418,824 and (B) 1,418,825, 6.6.22. Appl., 26.8. and 21.10.20.

The vulcanisation of rubber with sulphur is assisted by (A) a condensation product of formaldehyde and *p*-toluidine or (B) phenylhydrazine.—D. F. T.

Rubber and other like substances; Vulcanisation of ——. B. D. Porritt, Assr. to North British Rubber Co. U.S.P. 1,418,166, 30.5.22. Appl., 7.3.19.

See E.P. 129,798 of 1918; J., 1919, 688 A.

Caoutchouc; Art of vulcanising ——. C. W. Bedford and R. L. Sibley, Assrs. to Goodyear Tire and Rubber Co. U.S.P. 1,418,771, 6.6.22. Appl., 24.11.19.

See E.P. 173,545 of 1920; J., 1922, 149 A.

Caoutchouc; Art of vulcanising ——. C. W. Bedford, Assr. to Goodyear Tire and Rubber Co. U.S.P. 1,418,772, 6.6.22. Appl., 24.11.19.

See E.P. 130,857 of 1918; J., 1919, 731 A.

Caoutchouc and caoutchouc-like product; Manufacture of ——. P. Schidrowitz, Assr. to Catalpo, Ltd. U.S.P. 1,418,976, 6.6.22. Appl., 19.7.21.

See E.P. 170,682 of 1920; J., 1921, 898 A.

Rubber, caoutchouc, balata, guttapercha and similar substances; Machines for washing, milling, macerating, and cleaning ——. H. Berry and Co., Ltd., and P. G. Bradford. E.P. 180,831, 6.4.21.

Treating leather with rubber. E.P. 179,969. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins; The "hormone" theory of the formation of ——. W. Moeller. Z. Leder- u. Gerb.-Chem., 1921—2, **1**, 64—67, 73—80, 107—114, 143—145, 171—183.

Sugars are capable of yielding polyphenols, which are vegetable "hormones." The polyphenols are oxidised to the insoluble peptising substances which function largely in the production of leather. These insoluble tannins are present in plants in the form of glucosides and are thus rendered soluble. Humic acid contains a peptising system, and only those phenols which can pass through an intermediate quinone state can be oxidised to humic acid. The evidence of other research workers is adduced in support of the author's peptisation theory.—D. W.

Synthetic tannins; Properties of the sulphonic group in —— *II.* W. Moeller. Z. Leder- u. Gerb.-Chem., 1921-2, **1**, 203—210.

Various synthetic tannins in which the sulphonic group is combined with bases such as aluminium, chromium, or iron do not hydrolyse pelt to the same extent as does Neradol, in which the sulphonic group is free; and hence leathers tanned with these materials are more resistant to the hot-water test.—D. W.

Lime liquors used in the tannery; Chemistry of ——. W. R. Atkin. J. Soc. Leather Trades Chem., 1922, **6**, 200—206.

The theories of Procter and Wilson (J., 1916, 156, 645) and of Loeb (J. Gen. Physiol., 1918—1920) are extended to the alkaline swelling of hide in lime liquors. "Sharpening" agents, such as sodium sulphide and sodium carbonate, produce greater swelling because the osmotic pressure of sodium collagenate is greater than that of calcium collagenate at the same hydrion concentration. The smooth grain of skins unhaired with arsenic sulphide is due to the fact that only calcium collagenate is formed. The addition of salt to collagen, swollen by means of alkali, causes a repression of swelling exactly as in the case of pickling. A mixture of barium hydroxide and sodium chloride produces more swelling than barium hydroxide alone because of the interaction of the barium collagenate with the sodium chloride producing sodium collagenate, which has a greater swelling effect. There is no need to remove all the salt from salted hides before liming. The swelling properties of lime liquors should be determined by experiments on hide powder. The swelling should be compared with the p_H value, and graphical records preserved for successive liquors.—D. W.

Chrome tanning; A possible theory of ——. F. C. Thompson and W. R. Atkin. J. Soc. Leather Trades Chem., 1922, **6**, 207—209.

The existence of a negatively charged colloidal complex in chrome tanning solutions is indicated by the precipitate obtained when chromic chloride solutions are shaken with an amyl acetate solution of benzidine. Bassett and Pauli have both shown the probable existence of negatively charged colloidal chromium complexes. It seems possible that chrome tanning is effected by a negatively charged anion or colloidal particle containing chromium, which is produced from the green form of chromium sulphate. —D. W.

[*Gelatin;*] *Relation between hydrolysis* [*of*] *and adsorption* [*by* ——]. V. W. Moeller. Z. Leder- u. Gerb.-Chem., 1921-2, **1**, 160—165, 183—188.

Dry gelatin powder was soaked in water and various acids at $N/10$, $N/20$ and $N/100$ concentrations for from 1 hr. to 5 days and the amount of dissolved gelatin determined. The effect of some of the acid solutions, notably butyric acid, was to cause a diminution in the amount of hydrolysed gelatin. In most cases there was a re-adsorption of the hydrolysed gelatin after 5 days in $N/10$ solutions of organic acids, and in $N/100$ solutions of lactic and butyric acids. These results confirm the views of Kuhn (J., 1922, 111 A) that the swelling and hydrolytic effects of mineral acids differ from those of organic acids, but they also show that the action of acetic acid differs from that of lactic and butyric acids, the latter being the most suitable for tanning since they provide the necessary swelling with the least possible loss of hide substance.—D. W.

[*Leather chemistry;*] *Researches in the proteins* [*connected with*] ——. W. Moeller. Z. Leder- u. Gerb.-Chem., 1921-2, **1**, 188—203.

Blood fibrin as a typical true protein is less resistant to the action of alkalis, adsorbs very little vegetable tannin, is much hydrolysed by chrome liquors, and combines with a large amount of formaldehyde. Hide pelt which contains large amounts of true proteins, *e.g.* elastin and muscle protein, will tan differently to pelt from which these have been removed by strong liming or bating. True proteins readily adsorb chromium compounds, and their presence is disadvantageous for chrome-tanned upper leathers, as the excessive adsorption of chromium renders the leather hard and brittle. The true proteins are of value in sole leather, imparting firmness and resilience to the product, but they should be removed from pelts for vegetable-tanned upper leathers.—D. W.

Leathers; Resistance of different —— *to the action of acids.* W. Moeller. Z. Leder- u. Gerb.-Chem., 1921-2, **1**, 217—224.

Hydrochloric acid has the greatest destructive action on leather; sulphuric acid is less detrimental, and acetic acid has very little effect. Leathers tanned with quebracho and chestnut are equally affected by the action of acids, but leather tanned with quebracho extracts free from sulphite is much less resistant towards acetic acid. Sulphuric acid added during tannage up to a certain concentration is not absorbed by the pelt, but the same concentration of hydrochloric acid causes considerable hydrolysis. The addition of acetic acid during the tanning process produces a leather with a greater resistance to water.—D. W.

Protein systems [*gelatin*]; *Sol-gel equilibrium in* ——. R. H. Bogue. J. Amer. Chem. Soc., 1922, **44**, 1313—1322.

Viscosity-plasticity measurements made on gelatin solutions of various concentrations over a temperature range, 25°—60° C., with a MacMichael torsional viscosimeter, indicate that gelatin in aqueous solution follows the law of viscous flow at the higher temperatures, whilst at lower temperatures it exhibits plastic flow. The transition between the sol and gel form does not take place at any definite temperature, but extends throughout a rather indefinite period of temperature. At a given temperature the increase or decrease in viscosity with time is dependent on the hydrogen-ion concentration, the nature of the inorganic ions present, and the amount of hydrolysed protein in the system. It is considered that the viscosity of pure gelatin at any given hydrogen-ion concentration is inversely proportional to some function of the temperature. —W. G.

Elastic gels [*gelatin*]; *Structure of* ——. R. H. Bogue. J. Amer. Chem. Soc., 1922, **44**, 1343—1356.

The author re-states and amplifies his theory as to the catenary or fibrillar structure of gelatin-water systems (*cf.* J., 1920, 605 A), and in support quotes results on the influence of the electrolytes, of varying hydrogen-ion concentration, and of the valency of the combining ion on several of the characteristic properties of gelatin, namely, swelling, viscosity, jelly consistency, foam, turbidity, and alcohol number. Smith's data on mutarotation (J., 1919, 228 A) and Loeb's occlusion theory (J. Gen. Physiol., 1921, 3, 827; 1921—22, 4, 73, 97, 351) are shown to be in accord with the author's theory. (*Cf.* J. C. S., Aug.)—W. G.

Patents.

Hides; Process for unhairing ——. Soc. Pichard Frères. E.P. 163,294, 22.4.21. Conv., 12.5.20.

Well-dried hides are immersed in liquid air or other cold medium below −100° C. to render the hairs brittle, allowed to drain, and the hair removed by any suitable means.—D. W.

Tanning substances; Manufacture of artificial ——. M. Melamid. E.P. 180,353, 26.11.20. Addn. to 163,679 (J., 1922, 261 A).

Cresols, higher phenols derived from anthracene oil, or naphthalene, together with sulphuric acid in sufficient quantity to yield the sulphonated product, or the sulphonated products of these substances, are treated with acetylene in presence of mercury compounds. The product is dissolved in water, neutralised if necessary, and insoluble mercury compounds are filtered off.—D. W.

India rubber; Process for the treatment of leather with ——. A. McLennan. E.P. 179,969, 19.11.20.

Leather, after treatment with a mixture of carbon bisulphide or carbon tetrachloride with acetone, ether, benzene, paraffin, or petrol and sulphur, for the removal of grease, is buffed on the flesh side and is then soaked for 24—48 hrs. in a solution of rubber in a mixture of coal tar and petroleum solvents. It is then removed and worked by hand, after which the soaking and working are repeated. The leather is afterwards soaked in a rubber solution to which at intervals are added solutions containing gutta-percha, balata, gum mastic and dammar, and lastly a solution of sulphur chloride.—D. F. T.

Gelatin or similar material; Process and apparatus for producing uniform colorations of the exact shade required on ——. [Preparation of photometer scales.] O. Bornhauser. G.P. 351,243, 31.8.20.

Layers of gelatin or the like impregnated with a suitable precipitant are covered with an aqueous solution of a material which reacts with the precipitant to form a coloured, transparent precipitate in the gelatin layer. For example, gelatin is steeped in formaldehyde solution and then covered with ammoniacal silver solution, whereby a uniform dark brown precipitate of silver is formed in the gelatin. If permanganates are used as colouring agents, the gelatin requires no previous treatment. Graded photometer scales are prepared by pressing a frame separated into a number of compartments by partitions on to a layer of gelatin, and then pouring different quantities of the colouring solution into each compartment.—L. A. C.

XVI.—SOILS; FERTILISERS.

Calcium content of some virgin and cultivated soils of Kentucky; Comparison of the —— by an improved method for the estimation of this element. O. M. Shedd. Kentucky Agr. Exp. Stat. Bull. 236, Oct., 1921, 305—330.

Examination of certain soils indicates that cultivation has lowered the calcium content sufficiently to necessitate consideration of a possible deficiency of calcium as a plant food. The best types of soil usually contain the largest amounts of calcium, phosphorus, sulphur and iron. Determinations of "easily soluble" calcium by extraction with $N/5$ nitric acid and with carbonated water, indicate that the relative solubility of this element varies considerably in different soils. The method of estimating total calcium in soils has been improved. (*Cf.* J.C.S., July.)—A. G. P.

Soil; Micro-organisms concerned in the oxidation of sulphur in ——. III. Media used for the isolation of sulphur bacteria in the soil. S. A. Waksman. Soil Sci., 1922, 13, 329—336.

The classification of sulphur-oxidising organisms on physiological and morphological grounds is preferred to one determined by the type of oxidation or by the optimum reaction at which the organism acts. A review of the literature and of the media used by various investigators is given.—A. G. P.

Mineral plant food [from soils]; Removal of —— by drainage waters. J. S. McHargue and A. M. Peter. Kentucky Agr. Exp. Stat. Bull. No. 237, Nov., 1921, 333—362.

Analyses of numbers of samples of water from rivers, streams, etc., are recorded. The largest quantities of mineral matter were found in waters from limestone areas and the least in waters from sandstone areas, although the latter contained more potash than the former. The phosphate content of drainage waters varies with the amount present in the soil. High phosphate contents were always accompanied by high nitrate content. Waters containing most nitrates did not contain the greatest quantities of mineral matter. The leaching out of plant nutrients by drainage waters can be minimised by growth of clover crops on land which would normally be fallowed.—A. G. P.

Soil; Effect of limes containing magnesium and calcium on the chemical composition of the —— and upon plant behaviour. W. Mather. Soil Sci., 1922, 13, 337—354.

Soils treated with various types of lime and limestone were cropped for a number of years and periodical examinations of the soils are reported. Hydrated magnesian and calcic limestones produced practically the same crop yields. The effects of magnesium and calcium in limes and limestones on soil reaction are practically the same if the materials are applied in equivalent quantities. In limes both render the aluminium of the soil relatively insoluble. The calcium:magnesium ratio of soils treated with magnesian limestones was similar to that of unlimed soils. Variations of this ratio produced no apparent effect on plants. Magnesian limestones tend to increase the total nitrogen content of soils. Hydrated lime and magnesium oxide did not reduce the nitrogen content of the soil but slightly increased the amount of organic matter. —A. G. P.

Phosphates of aluminium, iron, and calcium; Comparative agricultural value of insoluble mineral ——. J. S. Marais. Soil Sci., 1922, 13, 355—409.

Comparison was made of the value of various mineral phosphates in pot-cultures and with various crops. The phosphates of aluminium and iron in some cases are superior to calcium phosphate, but in others are inferior. With all the phosphates assimilation is assisted by the rapid nitrification of urea. The chemically pure phosphates of the three metals are all equally available to plants, but the mineral phosphates of aluminium and iron in the form of basic hydrated phosphates are less available. This can be remedied by ignition. Lime improves the availability of pure and mineral aluminium phosphates, is without effect on iron phosphates, and tends to decrease the solubility of calcium phosphates. The effect on aluminium phosphates is explained by the removal of aluminium as insoluble calcium aluminate, and that on calcium phosphate by a disturbance of the equilibrium between the tri- and di-phosphates and carbonic acid. An alkaline soil solution tends to dissolve aluminium phosphate and thus aids its assimilation by the plant. Intimate contact between the plant roots and mineral phosphates is an important factor in their assimilation.—A. G. P.

Phosphates; Regularity of the assimilation of —— by plants. M. von Wrangell. Landw. Jahrb., 1922, 57, 1—78. Chem. Zentr., 1922, 93, I., 1387.

The conception that the assimilation of natural phosphates by plants is greater in those plants having a high $CaO:P_2O_5$ ratio (*cf.* J., 1921, 54 A) is confirmed. The ratio $CaO:P_2O_5$ for any particular plant varies with the reaction of the soil in which it grows. The assimilation of phosphate is lessened by the presence of calcium salts. There is a stoichiometric relationship between the amounts of lime and phosphoric acid taken up by a particular plant. The basic constituent of phosphatic fertilisers is important. The utility of calcium, iron, aluminium, and magnesium phosphates varies with the nature of the plant, and the non-utilisable constituents may be harmful. Thus cereals feeding on calcium phosphate leave residues of free lime and mustard treated with magnesium phosphates tends to liberate alkaline magnesium oxide.—A. G. P.

Patents.

Nitrates; Treatment of ——, particularly those used for fertiliser purposes. R. G. Browning and H. G. T. Boorman. E.P. 180,180, 27.4.21.

The hygroscopicity of commercial calcium and sodium nitrates is largely prevented by the admixture of a non-deliquescent, non-hygroscopic base, *e.g.*, carbonates of sodium, calcium, magnesium, etc.—A. G. P.

Soil mixture for a forced growing of potatoes and method for its manufacture. J. Husson. U.S.P. 1,417,248, 23.5.22. Appl., 28.12.20.

Sand is mixed with fertilisers containing nitrogen, phosphorus, and potash in the proportions 2—3% of nitrogen, 3—4% of water-soluble phosphoric acid, and 1—2% of potash.—A. G. P.

Potassium compounds; Treatment of leucitic rocks for the purpose of rendering —— available. G. A. Blanc and F. Jourdan. U.S.P. 1,418,356, 6.6.22. Appl., 21.10.20.

The rock is calcined, reduced to an impalpable powder, and treated with an organic acid.
—A. G. P.

Fertilisers containing phosphoric acid and potash; Process for the production of ——. T. Haege. E.P. 180,027, 15.2.21.

See U.S.P. 1,411,696 of 1922; J., 1922, 385 A.

Insecticides. U.S.P. 1,417,232 and 1,418,848. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Beet juices treated with magnesium bicarbonate; Simultaneous saturation applied to ——. K. Andrlik and W. Kohn. Z. Zuckerind. Czechoslov., 1922, 46, 404—410, 411—415.

Beet juices, syrups, and molasses were treated in the laboratory with sufficient lime to impart an alkalinity of about 0·1%, filtered, mixed with a solution of magnesium bicarbonate, and submitted to the process of simultaneous saturation previously described (Urban, J., 1922, 428 A). A considerable diminution of the colour and an appreciable increase in the purity of the product thus clarified resulted. Magnesium bicarbonate was prepared for this purpose from dolomitic lime by dissolving out the calcium hydroxide with a solution of sucrose and carbonating the residue.—J. P. O.

[Beet] juice; Distillation of ammonia from limed and carbonated —— and its influence on the composition of this juice. W. Kohn. Z. Zuckerind. Czechoslov., 1922, 46, 431—438.

In laboratory experiments limed beet juice when distilled in an apparatus provided with a dephlegmator yielded only 0·01 and 0·016% NH_3 when the volume of the distillates was 6 and 14% respectively. Juice which had been both limed and carbonated yielded 0·008 and 0·012% respectively. Generally juice which had been thus distilled was lower in purity, darker in colour, and higher in calcium content than that obtained according to the ordinary routine.—J. P. O.

Lactose; Action of ozone on solutions of ——. O. W. Schonebaum. Rec. Trav. Chim., 1922, 41, 422—424.

Ozone of low concentration does not decompose neutral or acid solution of lactose, even when ozonisation proceeds for 3 hrs. at 70° C. In alkaline solution the ultimate products are carbon dioxide and water, formic acid occurring as an intermediate product.—H. J. E.

Patents.

Adhesive; Manufacture of an —— from potato-starch. A. G. Bloxam. From J. Kantorowicz. E.P. 179,765, 23.3.21.

Potato flour is treated, without making a milky mixture, and in a medium containing no caustic alkali, with a peroxide or per-salt having an alkaline reaction, or with a neutral peroxide or per-salt in an alkaline medium. The proportions are such that complete transformation into soluble starch is avoided, *e.g.*, 100 kg. of flour is mixed with 2·5 kg. of ammonium persulphate and 1 kg. of ammonia solution (22° B.). After standing for at least 1 day, the product gives, when mixed with ten times its weight of water, a paste approximately equal in viscosity and softness to wheat starch paste.—A. G. P.

Dextrin substitute; Process for the production of a —— from extracted beet residues. F. Sichel, Chem. Fabr. "Liminer," and E. Stern. G.P. 351,002, 10.4.19.

Extracted beet slices are systematically leached with water at 70°—100° C. Leaching is stopped when the slices begin to pulp. Solutions thus obtained are easier to work up than those from the acid and pressure processes, and the residues are of value as a cattle food.—A. G. P.

Edible product obtained from the sugar juices of beets and process of obtaining it. P. Kestner. U.S.P. 1,419,057, 6.6.22. Appl., 30.6.20.

See E.P. 135,235 of 1918; J., 1920, 76 A.

XVIII.—FERMENTATION INDUSTRIES.

Zymase; Problem of the formation of —— in yeast. F. Hayduck and H. Haehn. Woch. Brau., 1922, 39, 97—100, 105—107, 110—113, 118—119, 122—123, 128—130.

The authors discuss the different theories which have been advanced to explain why certain yeasts capable of inducing active fermentation, such as those produced by the aeration process, are quite unsuitable for the preparation of active zymase or permanent yeast, the yeasts employed in Buchner's work being almost exclusively of the bottom fermenting brewery type. The experimental results obtained support the view that zymase exists in the yeast cell both in the free state and also in combination with the protoplasm as so-called plasma zymase, the zymase being largely in the uncombined condition in bottom brewery yeasts, but almost entirely combined in the yeast prepared by the aeration process. At the present time, however, many of the brewery yeasts in use in Germany are practically devoid of free zymase, the amount of the latter formed being apparently small owing to the deficient nutrition of the yeast resulting from the prevailing economic conditions; further, this small amount of enzyme and also the corresponding co-enzyme are destroyed by the action of the endotryptase and lipase respectively. By prevention of the action of the endotryptase during the maceration of the yeast by suitable alteration of the hydrogen-ion concentration, an extract is obtained which brings about active fermentation of sucrose in presence of added co-enzyme. On the other hand experiments made with yeast rendered permanent by treatment with acetone or by Lebedew's method show that German bottom-fermentation brewery yeasts yield amounts of free zymase similar to those observed under pre-war conditions. As regards the influence of toluene in restricting fermentation by living yeast cells, the results obtained support the view that a protecting layer of emulsion is formed, this preventing access of the sugar to the zymase. The authors have carried out a number of series of experiments with the *Torula* largely grown in Germany during the war for use as fodder and known as "mineral yeast." This organism is poor in zymase but rich in catalase, whereas with brewery yeast the reverse is the case. If, however, the torula is grown, in absence of air, in molasses solution containing nutrient salts, its content of zymase is considerably increased and that of catalase markedly decreased, but no relation can be traced between the fermentative power and the proportion of nitrogen present in the organism. When repeatedly grown under anaerobic conditions, the cells of the torula assume a more spherical shape than they originally possess, but they continue to exhibit the high content of free nucleic acids characteristic of true torulæ; at the same time the baking value becomes at least equal to that of commercial yeast prepared by the aeration process, although the yield is decidedly less than that obtained with aeration. Close parallelism exists between the formation of zymase and that of nucleic acids in this organism, and a good idea of the fermentative activity may be obtained by the extent of the green spots formed when the cells are fixed by heating and then treated successively with Carbol-Methylene Blue, water, and diaminophenylacridine.—T. H. P.

Yeast; Capacity of —— to decompose acid amides. W. Dieter. Z. physiol. Chem., 1922, **120**, 281—291.

Experiments with a top-fermentation pure culture yeast show that when the conditions are such that the yeast ferments but does not grow, it does not remove the amide nitrogen from asparagine and other acid amides.—S. S. Z.

Determining sugars by fermentation. Costantino. *See* XVII.

Yeast nucleic acid. Steudel and Peiser. *See* XX.

Patents.

Yeast; Manufacture of ——. R. Gilmour. E.P. 180,043, 17. and 23.2.21.

Diluted molasses is acidified and boiled with bone charcoal and clarified by the addition of malt combings or other albuminoid material, and filtered. Suitable yeast foods, *e.g.*, ammonium salts, phosphates, etc. are added to the mixture, which is neutralised, if necessary, with ammonia. After filtration the liquor is seeded with yeast and allowed to ferment. Neutrality is maintained by periodic additions of potassium, calcium, or magnesium carbonates. Towards the end of the fermentation lactic acid is added. After a further few hours the yeast is separated and pressed. The initial treatment with bone charcoal and with malt combings may be carried out in two separate stages.—A. G. P.

Colouring matter for beer; Process of manufacturing a ——. H. Lüers. U.S.P. 1,418,945, 6.6.22. Appl., 18.2.21.

Hygienic food. U.S.P. 1,417,412. *See* XX.

XIXa.—FOODS.

Fat obtained from the milk of Egyptian goats. A. Azadian. Bull. Soc. Chim. Belg., 1922, **31**, 171.

In order to fix a standard, 104 samples were examined. The maximum, minimum, and mean values were: for total solids, 16·55, 10·65, 12·54; for fat, 7·35, 2·45, 4·04; and for solids-not-fat, 9·95, 7·6, and 8·50% respectively. Six samples of goats' milk butter were also examined and the detailed results are given.—H. J. E.

Potato flour; Estimation of moisture in ——. E. H. Vogelenzang. Chem. Weekblad, 1922, **19**, 251—253.

Though this determination is of considerable commercial importance, the methods usually employed for it are unsatisfactory, and lead to inaccurate and varying results. It is desirable that a standard method should be adopted; drying should not be carried out in the air, unless specially dried air is used, and precautions should be taken to prevent the dried flour taking up moisture whilst cooling in the desiccator, since it is very hygroscopic. —S. I. L.

Vitamins; The testing of foodstuffs for ——. J. C. Drummond and A. F. Watson. Analyst, 1922, **47**, 235—246.

Details are given of the method of carrying out physiological tests on rats for the presence of the three vitamins in foodstuffs. Young, healthy rats of not more than 50 g. body-weight are fed on a ration of purified foodstuffs from which all traces of the vitamin to be tested for have been removed. These rations are specified for each of the three vitamins. When the rats have shown no further increment of weight for 14 days, the substance to be tested is administered in a daily ration of known weight. A curve is given, showing the sharp recovery which follows the administration of 0·05 g. daily of cod-liver oil, and a series of curves showing the loss of growth-promoting power in a sample of coal-fish liver oil during aeration at 100° C. The method has been used to show that samples of butter vary very considerably in the amount of vitamin they contain. Oleo oil also shows marked variations, which appear to be seasonal and dependent on the state of the pasturage. The amount of vitamin B in milk depends entirely on the food of the cow. Many commercial yeast extracts are almost the richest sources of this vitamin available as foodstuffs. The monkey is the best animal for testing for vitamin C, but the guinea-pig is generally used. Testing is rendered more difficult by the fact that the guinea-pig is entirely herbivorous. The potency of the food supplement added is judged from the "dosage" necessary to prevent the onset of, or to cure established scurvy. The antiscorbutic value of milk is dependent on the diet of the animals. Lemon-juice possesses a very much higher antiscorbutic potency than lime juice.—H. C. R.

Vitamins. S. Fränkel. Pharm. Monatsh., 1922, **3**, 17—18. Chem. Zentr., 1922, **93**, II., 1225—1226.

The action of substances rich in vitamins in accelerating the rate of yeast fermentation was determined. The amount of carbon dioxide liberated in a given period of time was proportional to the vitamin content. The vitamin was prepared as follows: The material was exhausted with nearly boiling 90% alcohol, and then heated with water. The aqueous extract was concentrated *in vacuo*, alcohol was added, and, after filtering, the alcoholic filtrate was added to the initial alcoholic extract. The whole was concentrated and extracted with ether to remove fats etc. The residual liquor was treated with basic lead acetate, filtered, and excess of lead was removed with hydrogen sulphide. The purified solution contained unaltered vitamin, and was further treated with mercuric chloride, excess of which was removed with hydrogen sulphide, and the hydrochloric acid removed with lead and with silver.

Other inactive material was removed with picrolonic acid, and finally the active substance was precipitated with phosphotungstic acid; 99·8% of the inactive substances was thus removed. Most animal organs were poor in vitamins; more was found in the nerve-system, and most in the grey outer layer of the cerebellum. Among plant foods leeks showed the greatest activity. Roasted coffee is considerably more active than unroasted. The acceleration of fermentation by these substances was apparent with yeast juice as well as with the yeast itself. Choline and β-amino ethyl alcohol retarded fermentation. Vitamins have basic characteristics. The accelerating action of vitamins on the action of extra-cellular enzymes such as pepsin, trypsin, diastase, and catalase was very small.—A. G. P.

Vitamins; Distribution of fat-soluble —— in marine animals and plants. J. Hjort. Proc. Roy. Soc., 1922, B 93, 440—449.

Rats which had been previously kept on a diet deficient in fat-soluble vitamin showed a marked increase in growth on administration of dried green algæ and dried cod's roe, also of extracts of these substances prepared with fat-solvents. It is suggested that the fat-soluble vitamins in the sea originate in plants and that their distribution may have important bearings on the periodicity in the growth of fishes.—C. R. H.

Carbohydrate content of navy beans. M. Eichelberger. J. Amer. Chem. Soc., 1922, 44, 1407—1408.

The author draws attention to results obtained by herself in 1919 which are in fairly close accord with those of Peterson and Churchill (J., 1921, 525 A) on the composition of navy beans (*Phaseolus vulgaris*).—W. G.

Protamines. R. E. Gross. Z. physiol. Chem., 1922, 120, 167—184.

When clupeine is heated for 80 mins. with 4% (by vol.) sulphuric acid at 160° C. it loses the property of giving the biuret reaction. The hydrolysed product contains arginine, monoamino acids, and a compound similar to a dipeptide consisting of a combination of at least two molecules of arginine. By precipitating with phosphotungstic acid in alcoholic solution it is possible to separate free arginine from the arginine peptide. The authors confirm Nelson and Gerhardt's observations that in clupeine the monoamino acids are linked together.
—S. S. Z.

Saponins [in lemonade etc.]; Differentiation and quantitative determination of ——. L. Kofler. Z. Unters. Nahr. Genussm., 1922, 43, 278—287.

By employing the usual methods it is impossible to determine the identity of a saponin when it is not available in the pure state or must be isolated from a substance such as lemonade. In addition to the hæmolytic action of saponins the author makes use of their foaming power, the "foam number" being obtained by shaking 10 c.c. of a series of solutions of the saponin of different concentrations in test tubes 16. mm. wide for 15 secs. The foam number is given by the dilution in that tube in which the foam stands 1 cm. high after 15 mins. The hæmolytic index is determined in the usual way. If the hæmolytic index is divided by the foam number a quotient is obtained which is independent of the state of purity of the saponin. This quotient varies very markedly in the case of the six different saponins investigated, and has a characteristic value for each of them varying from zero in the case of glycyrrhizin to 10 in the case of Merck's digitonin. By this means saponins separated from artificial lemonades by methods of Brunner and Rühle (J., 1908, 954; Z. Unters. Nahr. Genussm., 1912, 23, 566; 1914, 27, 192) can be readily identified and quantitatively determined by comparing the hæmolytic index and foam value obtained with those tabulated for the saponin in question. It should be possible to specify a maximum value for the "poison/foam" quotient, which should not be exceeded by saponins used in foodstuffs. The figure 1 or 0·5 is suggested.—H. C. R.

Synthetic sweetening agents. Beyer. *See* XX.

Patents.

Food products; Manufacture of —— from meats and vegetable substances. W. and C. O. Spear. E.P. 179,705, 21.2.21.

Meats, vegetables, etc., are cleaned with warm water, with or without antiseptics, pulped, dried, and if necessary smoked by the means described in E.P. 166,698 (J., 1921, 673 A).—A. G. P.

Casein products; Production of ——. H. V. Dunham. E.P. 180,018, 12.2.21.

An alkali casein solution is treated with sufficient acid material containing citric acid to render the liquid acid to litmus and produce a suspension of finely divided or deflocculated casein, the operation being conducted at a temperature which is higher or lower according to the higher or lower concentration of the solutions used. The product is dried for use as a substitute for skim-milk powder. The dried product produces with water a colloidal suspension of casein free from substantial quantities of fatty material.—H. H.

Meat, fish, and like edible substances; Treating —— for curing and like purposes. P. C. Rushen. From International Meat Smoking Corp. E.P. 180,497, 2.4.21.

The meat etc. is electrified, and while in that condition is subjected to the action of a gas or smoke. A pulsating direct current of a voltage sufficient to produce 8-in. sparks in air may be used. The meat may be suspended within the treating chamber from one electrode between two electrodes of the opposite polarity, or may be suspended from conveyor chains which are connected with one electrode and move through the chamber between electrodes of the opposite polarity.—H. H.

Food substances; Reducing semi-fluid —— to dry powdered form. J. C. MacLachlan. U.S.P. 1,417,083, 23.5.22. Appl., 9.4.21.

Cooked oatmeal, in a semi-fluid condition, is discharged centrifugally into a chamber and meets blasts of hot dry steam and heated air. The product is a dry, coarse powder.—A. G. P.

Edible product and process of making same. C. Ellis. U.S.P. 1,417,893, 30.5.22. Appl., 16.12.18.

A composition comprising medicinal petroleum oil, hydrogenated oil, butyric glyceride, and water, and having a consistency from that of butter-fat to that of lard.—H. H.

Evaporating pan [for milk etc.]. C. E. Rogers. U.S.P. 1,417,943, 30.5.22. Appl., 25.1.19.

The pan is fitted with a series of superposed steam heating units, each independently connected with the steam main. Each unit is in the form of an inner and an outer coil connected together at adjacent ends with a common inlet and a common outlet. The spaces between the coil ends of adjacent units are on opposite sides of the pan.
—H. H.

Bacteria capable of forming lactic and acetic acids; Process of producing and utilising pure cultures of leavening ——. E. Beccard. G.P. 350,874, 21.2.20.

Aqueous extracts of flour, after sterilisation by a cold process, are added at the lowest possible temperature to a concentrated solution of gelatin or agar, so that the solution solidifies in the cold. The leavening bacteria, isolated by means of cultures on the nutrient medium prepared as described, are added together with yeast to dough.—L. A. C.

Mineral waters and beverages; Preparation of artificial —— *containing silicic acid.* Lecinwerk E. Laves. G.P. 350,247, 9.4.19. Addn. to 337,796 (J., 1921, 637 a).

Artificial mineral waters containing a higher percentage of silicic acid than naturally occurring waters are prepared with the use of stable solutions of colloidal silicic acid prepared as described in the chief patent. A solution of an alkali silicate is mixed with a solution containing an excess of an inorganic or organic acid, with or without the addition of compounds which evolve carbon dioxide, salts with a therapeutic action, vegetable extracts, flavouring essences, and sweetening agents. The constituents of the two solutions may be prepared beforehand in the form of powders, granules, or tablets.—L. A. C.

Flour and grits from cereals; Method of sterilising —— *whilst at the same time improving the baking quality.* K. Dienst. E.P. 180,496, 2.4.21.

See G.P. 335,406 of 1917; J., 1922, 30 a.

Organic matters and particularly meat and fish; Process for preserving in the fresh condition ——. L. A. C. Cholet. U.S.P. 1,418,233, 30.5.22. Appl., 10.1.21.

See E.P. 171,637 of 1921; J., 1922, 30 a.

Hygienic food. U.S.P. 1,417,412. *See* XX.

XIXb.—WATER PURIFICATION; SANITATION.

Formaldehyde; Lamp for producing ——. E. Berger. Comptes rend., 1922, 174, 1471—1474.

A modified form of Tollens' lamp (J., 1895, 592) is described, in which two types of catalyst are used, namely compressed lampblack containing 20% of copper oxide, and, secondly, silvered asbestos board. The heat from the compressed catalyst in the first case or from the gauze container of the catalyst in the second case is used to vaporise the methyl alcohol as it is brought up from the container by a cottonwool wick. The lamp uses about 100 g. of methyl alcohol per hour, and the yield with the first type of catalyst is 30% and with the second type 35—40% (in one case a yield of 45% was obtained). The second type of catalyst needs to be heated to a red heat in an external flame before use, but it gives the best result, and has been adopted for use in disinfecting surfaces.
—W. G.

Patents.

Water purifiers. J. B. Gail and N. Adam. E.P. 180,420, 21.2.21.

An automatic apparatus for clarifying water by treatment with lime water and another reagent, *e.g.*, sodium carbonate. Lime water is added mechanically in controlled amounts to the main flow. Means are provided for thorough mixing of the reagents with the water before filtering.
—A. G. P.

Water; Process of purifying and decolorising ——. M. F. Newman, Assr. to W. B. Scaife and Sons Co. U.S.P. 1,418,013, 30.5.22. Appl., 5.9.19.

Water contaminated with soil acids, vegetable extracts, etc., is clarified and decolorised by treating it successively with an alkali in association with a bleaching agent, a coagulant, and a reagent for removing excess of bleaching agent.—H. H.

Sewage and the like; Treatment of ——. *Treatment of sewage, water, and the like.* H. Daw. E.P. (a) 179,896 and (b) 180,272, 17.1.21.

(a) Sewage etc. is aerated by allowing it to fall through the air, a portion being withdrawn for this purpose from the sewage on its way from the storage chamber to the sedimentation chamber and allowed to fall as fine spray back into the storage chamber. (b) A sewage treatment plant consists of a sedimentation chamber and a sludge chamber, the former being at a higher level than the latter and provided with passages to the latter at the lowest point of its sloping side. The sedimentation chamber has also longitudinal baffles for assisting in settling and directing any gas that may be evolved to the open air.—B. M. V.

Hydrocyanic acid; Method of generating —— [*for fumigating*]. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler, and O. Liebknecht. E.P. 180,118, 15.3.21.

Alkali cyanides are mixed with partially dehydrated salts of metals forming unstable cyanides, *e.g.*, magnesium or aluminium sulphates. The heat necessary to drive off hydrocyanic acid from the moistened mixture is supplied by the heat of hydration of the salts themselves or of other salts added for that purpose.—A. G. P.

Insecticides; Method of making ——. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,417,232, 23.5.22. Appl., 6.2.19. Renewed 24.10.21.

A suitable lead compound is treated with excess of arsenic acid, and the residual acid neutralised with excess of an alkaline-earth hydroxide.—A. G. P.

Arsenate insecticides; Process of making ——. W. H. Swenarton. U.S.P. 1,418,848, 6.6.22. Appl., 10.12.19.

An alkali salt is mixed with sufficient arsenic acid to convert the major portion of the salt into a soluble arsenate, and to this mixture is added a salt of a metal forming an insoluble hydroxide. The insoluble arsenate is filtered off and the cycle of operations repeated, utilising the above filtrate.
—A. G. P.

Water, sewage, or the like; Process for automatically regulating the addition of a treating agent to ——. J. S. Simsohn. E.P. 180,586, 8.7.21.

See U.S.P. 1,388,613 of 1921; J., 1921, 788 a.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Yeast nucleic acid. III. H. Steudel and E. Peiser. Z. physiol. Chem., 1922, 120, 292—295. (*Cf.* J., 1921, 60 a; 1922, 153 a.)

Guanylic acid can be obtained from yeast nucleic acid when the sodium salt of the latter is treated in alkaline solution. The guanylic acid portion of the molecule can in this way be completely removed if the reaction takes place at ordinary temperature. No guanylic acid is removed by similar treatment at 0° C.—S. S. Z.

Sweetening agents; Synthetic ——. O. Beyer. Z. angew. Chem., 1922, 35, 271—272.

The methods given for the quantitative separation of *o*- and *p*-toluenesulphonamide and of saccharin and *p*-sulphaminobenzoic acid by the author in his book *Kontrolle und Herstellung von Saccharin* were never put forward by him as being either reliable or accurate, but only recorded to show on what lines experiments had been made by others. —G. F. M.

Vanillin glyceride. F. D. Dodge. J. Amer. Chem. Soc., 1922, 44, 1405—1407.

A crystalline deposit formed in a flavouring mixture of alcohol, glycerol, and vanillin on standing was shown to be vanillin glyceride, m.p. 160°—162° C., formed by the condensation of 1 mol. of each compound. The reaction between these two compounds is much accelerated by the presence of mineral acids, but, on the other hand, the resulting glyceride is readily hydrolysed by acids.—W. G.

Reduction of organic compounds; Use of the oxides of platinum for the catalytic ——. I. V. Voorhees and R. Adams. J. Amer. Chem. Soc., 1922, 44, 1397—1405.

When chloroplatinic acid is fused with sodium nitrate at about 450° C. a brown oxide of platinum is obtained which is an excellent catalyst for the reduction of various types of organic compounds (vanillin, ethyl methyl ketone, phenol, salicylaldehyde, nicotinic acid). The speed of reduction with this catalyst is greater than when ordinary platinum black is used. The most satisfactory conditions for preparing this oxide in its most active form have yet to be worked out.—W. G.

Catalysis. II. Dehydration and addition reactions of ethyl alcohol: the formation of acetal and mercaptans. F. A. Gilfillan. J. Amer. Chem. Soc., 1922, 44, 1323—1333.

Ethyl alcohol vapour alone or in the presence of carbon dioxide is not decomposed when passed over pumice at 500° C. Thorium oxide does not act exclusively as a dehydrating catalyst for this alcohol, as, under certain conditions, a considerable amount of acetaldehyde is produced by dehydrogenation. In the presence of carbon dioxide a quantity of acetal is obtained with thorium oxide as catalyst. The oxide is inactivated as a dehydrating catalyst if it is strongly calcined or heated for a long time at a low temperature before use. Up to about 340° C. the blue oxide of tungsten is a more effective dehydrating agent than is thorium oxide, but at higher temperatures the two oxides are of practically equal efficiency. Titanium oxide has no dehydrating action up to 355° C. In no case was any ether produced from the alcohol. Using any of the three metallic oxides as catalysts at 300°—400° C., a mixture of absolute alcohol and carbon bisulphide gave considerable quantities of ethyl mercaptan, titanium oxide being the most active catalyst for this reaction. Pure dry carbon bisulphide is not decomposed when vaporised over pumice or the blue oxide of tungsten at 400° C., but in the presence of a trace of moisture hydrogen sulphide is obtained.—W. G.

Acetone; Source of error in the colorimetric detection of ——. A. Troise. Ann. Chim. Analyt., 1922, 4, 177—178.

Istycin (1.8-dihydroxyanthraquinone) gives a violet coloration with Lieben's reagent (sodium nitroprusside in acetic acid and ammonia) similar to that produced by acetone. (*Cf.* J.C.S., August.) —A. R. P.

Iodine value. Holde and others. *See* XII.

Patents.

Aromatic [hydr]oxyaldehydes and their derivatives; Manufacture of ——. Soc. Chim. des Usines du Rhône. E.P. 160,765, 24.2.21. Conv., 24.3.20.

Aromatic hydroxyaldehydes are obtained, in most cases in pure condition and in good yield, by condensing a phenol with an ester or ether of the hypothetical methylene glycol, $CH_2(OH)_2$, by means of an acid condensing agent in presence of a nitroso-compound. *Example.* A mixture of 40 pts. of guaiacol, 100 pts. of methylal, and the nitrosodimethylaniline obtained from 80 pts. of dimethylaniline is heated on a water bath for 1—2 hrs. in 500 pts. of methyl alcohol, whilst gaseous hydrogen chloride is continuously bubbled through. The product is then cooled, diluted with water, and freed from alcohol by steam distillation. Vanillin is extracted from the resulting aqueous solution with ether or benzene. Instead of methylal, methylene chloride, methylene diacetate, or methylene sulphate may be used with similar results.—G. F. M.

Amino-phenols or aromatic amino-acids; Production of ——. W. Lewcock, W. G. Adam, N. E. Siderfin, and W. L. Galbraith. E.P. 179,753, 19.3.21.

Aminophenols or aromatic amino-acids may be obtained by the reduction of nitro- or azo-phenols or aromatic acids with hydrogen sulphide in presence of an alkali carbonate. The compound to be reduced may be dissolved wholly or in part in a solution of the alkali carbonate, or the latter may be added to an already prepared solution of the alkali phenoxide or salt. The hydrogen sulphide need not be pure, but may be employed, for example, in the form of the waste gases from the ammonia scrubbers of gasworks, containing only about 15% H_2S and a large proportion of carbon dioxide. *Example.* 50 pts. of benzeneazosalicylic acid is added to 44 pts. of sodium carbonate dissolved in ten times its weight of water, and the mixture is treated in a still at about 100° C. with a waste gas until no more hydrogen sulphide is absorbed and no more aniline passes over. The solution is allowed to cool in an atmosphere of the gas, and sulphur and aminosalicylic acid are fractionally precipitated by the cautious addition of acid. The yield is 85—90%.—G. F. M.

Formaldehyde or its polymers; Preparation of —— from mixtures of carbon monoxide and hydrogen. E. J. Lush. E.P. 180,016, 12.2.21.

When mixtures of carbon monoxide and hydrogen in suitable proportions, such as may be obtained by the purification of "suction" or water-gas, are passed rapidly over catalysts prepared preferably from a mixture of 4 pts. of nickel, 1 pt. of copper, and 5 pts. of alumina, large quantities of formaldehyde or its polymerisation products are formed, and the residual gas consists mainly of methane and hydrogen. The gas is preferably forced through the catalyst at an initial temperature of 300°—400° C. and under 10 atm. pressure, and as rapidly as will ensure that the temperature does not fall below 160°—180° C. on leaving the catalyst. To promote rapid cooling thereafter the high-pressure gas is allowed to issue from a small constriction and is then led into water scrubbers to remove the formaldehyde. In order to restore the activity of the catalyst, steam is blown through periodically, or, preferably, is mixed with the gaseous mixture.—G. F. M.

Formaldehyde; Production of —— from ethylene. R. Willstätter. G.P. 350,922, 9.4.18.

A mixture of ethylene and a large excess of oxygen over that required to oxidise the ethylene to formaldehyde, maintained under reduced pressure and/or mixed with an inactive gas as diluent, is heated for a short time above 500° C., and the formaldehyde produced is rapidly separated from the mixed gases.—L. A. C.

Medicine and hygienic food. J. C. Richard. U.S.P. 1,417,412, 23.5.22. Appl., 14.3.14.

Fruit juice mixed with a non-toxic neutralising agent is subjected to lactic acid fermentation with *B. bulgaricus.*—A. G. P.

Olefines, etc.; Process of oxidising ——. C. Ellis, Assr. to S. B. Hunt. U.S.P. 1,418,368, 6.6.22. Appl., 17.5.18.

Ketones and fatty acids are obtained from the acid extract of olefines from cracked petroleum by diluting the acid extract and treating it with dilute nitric acid.—T. A. S.

Acetylene; Method for the chlorination of ——. K. Róka, Assr. to Holzverkohlungs-Ind. A.-G. U.S.P. 1,418,882, 6.6.22. Appl., 3.2.22.

Chlorine and acetylene are caused to interact at high temperature with the aid of steam.—H. H.

Iodine-malt preparations; Manufacture of ——. Gehe und Co. A.-G. G.P. 348,412, 22.2.21.

An aqueous solution of malt extract is evaporated *in vacuo* with such a quantity of an alcoholic solution of iodine that the dry product contains 0·1% I. Instead of an alcoholic solution of iodine, an aqueous solution of sodium iodide and iodate together with hydrochloric acid may be used. The product, which is of therapeutic value, does not give a blue colour with starch test-paper.

Butyric aldehyde; Manufacture of ——. D. A. Legg, Assr. to M. A. Adam. U.S.P. 1,418,448, 6.6.22. Appl., 22.11.21.

See E.P. 173,004 of 1920; J., 1922, 197 A.

Mono- and di-β-[hydr]oxyethylaminobenzoic esters; Process for the manufacture of ——. J. Altwegg and J. Landrivon, Assrs. to Soc. Chim. Usines du Rhône. U.S.P. 1,418,900, 6.6.22. Appl., 13.6.19.

See E.P. 128,552 of 1919; J., 1920, 280 A.

[Hydr]oxyaldehydes; Process for the manufacture of aromatic ——. F. Bidaud, Assr. to Soc. Chim. Usines du Rhône. U.S.P. 1,418,904, 6.6.22. Appl., 26.2.21.

See E.P. 160,765 of 1921; preceding.

Tropinone monocarboxylic-acid esters and preparation of the same. R. Willstätter, O. Wolfes, and H. Maeder. U.S.P. 1,419,091, 6.6.22. Appl., 26.8.21.

See G.P. 344,031 of 1919; J., 1922, 270 A.

Tropinone monocarboxylic-acid esters; Preparation of ——. O. Wolfes and H. Maeder. U.S.P. 1,419,092, 6.6.22. Appl., 26.8.21.

See E.P. 153,917 of 1920; J., 1922, 436 A.

Purifying organic substances. E.P. 179,991. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[Photographic] desensitisers; New ——. R. E. Crowther. Brit. J. Phot., 1922, **69**, 351—353.

Two new desensitisers, "Pinakryptol" and "Pinakryptol Green," were investigated and compared with Phenosafranin. As regards desensitising efficiency, "Pinakryptol" is equal to Phenosafranin, and "Pinakryptol Green" is more efficient. The new dyes, moreover, are practically non-staining, a maximum of ten minutes' washing sufficing to remove all signs. The effects of the dyes on development were investigated for several developers, and the results are tabulated. "Pinakryptol" causes a pronounced retardation of development. The dyes do not interfere with the "speed" of a given plate.—W. C.

Patents.

Photographic dry plates or films; Method of treating ——. J. D. Bagley. U.S.P. 1,417,791, 30.5.22. Appl., 7.2.21.

Photographic dry plates or films are treated with alcohol after exposure and before development and subjected to the action of a photographic developer while still wet with alcohol.—W. C.

Photographic film; Antistatic ——. A. F. Sulzer, Assr. to Eastman Kodak Co. U.S.P. 1,418,405, 6.6.22. Appl., 25.4.21.

The support for the sensitive coating of an antistatic photographic film comprises sufficient nitrocellulose to produce, if alone, static markings in the coating, and sufficient of a cellulose ether to prevent the static markings being formed.—W. C.

Photographic film. E. Wolff. G.P. 345,734, 15.8.20.

On the actual film support a number of films each sensitised for a certain colour are arranged in suitable order. Colour selection is thereby rendered possible for visible and invisible rays without the use of filters. In addition to these, sensitisers, such as Dicyanin for red, and Erythrosin for green, an absorbing dye for blue rays, *e.g.*, Filter Yellow K, may be added to the emulsion. The different sensitiveness of the constituent emulsions can be equalised in this way. The exposure required is considerably shorter than with filters, and no diffuseness is obtained. The sequence red, green, blue is best for cinematograph films, but in colour photography other arrangements are better.
—W. C.

Photographic developers. J. Hauff und Co. E.P. 154,198, 22.11.20. Conv. 23.10.18.

See G.P. 327,111 of 1918; J., 1921, 371 A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1736 of 1891; J., 1893, 374.)

Photometer scales. G.P. 351,243. *See* XV.

XXII.—EXPLOSIVES; MATCHES.

Detonators; The lead-plate test as applied to commercial ——. B. Grotta. Chem. and Met. Eng., 1922, **26**, 1126—1132.

The test is described and two simple forms of apparatus are illustrated. A series of six standard markings on the lead plates are illustrated. These were obtained by tests with No. 6 commercial detonators and give the effect of detonators of various qualities down to complete ineffectiveness on the plates. Comparative tests carried out on samples of commercial dynamite indicate that detonators giving plates corresponding to the first three standard plates are suitable for use in blasting operations. The influence of the size of the charge, moisture, potassium chlorate content, indentation of shells, and hardness of shells on the detonation, as indicated by the lead-plate test, is dealt with.—H. C. R.

Nitrotoluenes. Binary systems of m-nitrotoluene with another nitrotoluene. J. M. Bell and J. L. McEwen. J. Ind. Eng. Chem., 1922, **14**, 536—537.

The binary system, *m*-nitrotoluene-*o*-nitrotoluene forms a stable eutectic at −31·65° C. containing 48% of the *m*-constituent and a metastable eutectic containing 46% of the same constituent at −39° C. The system *m*-nitrotoluene-*p*-nitrotoluene forms an eutectic at −2·8° C. containing 37% of the *p*-constituent.—J. F. S.

Patents.

Priming compositions; Manufacture of ——. W. Friederich. E.P. 180,605, 31.8.21.

Combinations of explosive and non-explosive compounds with azides of heavy metals, such as lead azide, are obtained in the form of mixed crystals by gradually mixing solutions of readily soluble salts of the particular compounds and readily soluble azides with solutions of metallic salts. Alternatively, crystals serving as core crystals may be levigated in one of the solutions to be precipitated so that on subsequent precipitation crystals are obtained covered with layers of different compounds used in priming compositions. The elongation of the crystals of lead azide is thus overcome and the explosive obtained in a form more suitable for loading. Basic lead azide, lead carbonate, basic chlorides and sulphates, neutral and basic salts of nitrated phenols and other nitro compounds may thus be associated with lead azide.—H. C. R.

High explosive and process of preparing the same. T. L. Davis. U.S.P. 1,419,027, 6.6.22. Appl., 16.4.21.

A high explosive consists of pentanitronaphthol. —H. C. R.

Priming composition. Rheinisch - Westfälische Sprengstoff A.-G. G.P. 309,210, 1.5.18.

Lead trinitroresorcinate is used alone or in admixture with other explosives, with the exception of mercury fulminate. Normal lead trinitroresorcinate explodes successfully if heavily tamped. Fuses can be made with the aid of a damping material, and these are cheaper than those produced from mercury fulminate and are insensitive to hammering, cutting or crushing. They burn easily with little deflagration, without detonation, and are not injured by treatment in water and will explode an explosive without the use of a detonator. The velocity of detonation is somewhat higher than that of mercury fulminate fuses and varies from 6000 to 7000 m. per second according to the kind of damping agent employed.—A. G.

XXIII.—ANALYSIS.

Membrane filters; Treatment of ——. G. Jander. Z. angew. Chem., 1922, 35, 269.

To restore a smooth glazed surface to membrane filters which have become rough, the membrane is heated in distilled water for about ½ hr. at 75°—80° C., and then clamped tightly between two plate glass surfaces, care being taken that no air bubbles are enclosed. The whole is then heated again for 1 hr. in distilled water in a porcelain dish at the same temperature, the clamps being tightened up from time to time. After cooling the glass plates are unclamped and the membrane, which now has the desired glossy surface, is removed. The pores of the membrane will have been to a certain extent closed by this treatment and filtration will be somewhat slower. To preserve the membrane filter in good condition it should always be kept under water in closed vessels, and for preventing the growth of moulds a bright piece of copper foil placed in the bottom of the vessel is quite effective.—G. F. M.

Electrometric titration; Simple method of —— in acidimetry and alkalimetry. P. F. Sharp and F. H. MacDougall. J. Amer. Chem. Soc., 1922, **44**, 1193—1196.

A number of constant and reproducible electrodes have been prepared which are electrometrically equivalent to hydrogen electrodes dipping in solutions of various known hydrogen ion concentrations. Such electrodes are extremely useful in cases where it is necessary to titrate a solution of an acid to an end point corresponding to a definite hydrogen ion concentration. In such a case the half cell containing a hydrogen electrode and the solution to be titrated is connected with the electrode which has the same PD as the hydrogen electrode will have when the titration is completed. A solution of alkali is then run into the acid until a galvanometer indicates that the whole cell, comparison electrode/KCl (sat)/titration liquid /H_2,Pt, has a zero EMF. The following are the comparison electrodes together with the potentials against a normal calomel electrode, and the equivalent hydrogen ion concentrations.

Cadmium amalgam with 12–12·5% Cd—		
0·52 c.c. KI in 100 c.c. sol.	EMF, 0·5195 volt	= $H^{\cdot}\ 10^{-4}N$
2·90 c.c. KI ,, ,, ,,	,, 0·5609 ,,	= $H^{\cdot}\ 10^{-4.7}N$
6·14 c.c. KI ,, ,, ,,	,, 0·5786 ,,	= $H^{\cdot}\ 10^{-5}N$
67·50 c.c. KI ,, ,, ,,	,, 0·6378 ,,	= $H^{\cdot}\ 10^{-6}N$
Lead amalgam with 12–12·5% Pb, and lead iodide—		
100 c.c. $CdSO_4$ + 0·20 c.c. KI ..	EMF, 0·6967 volt	= $H^{\cdot}\ 10^{-7}N$
10 c.c. $CdSO_4$ + 10 c.c. KI in 100 c.c. sol.	,, 0·7560 ,,	= $H^{\cdot}\ 10^{-8}N$
100 c.c. $CdSO_4$ + 26·40 c.c. KI	,, 0·8151 ,,	= $H^{\cdot}\ 10^{-9}N$
2 c.c. $CdSO_4$ + 48·7 c.c. KI in 100 c.c. sol.	,, 0·8743 ,,	= $H^{\cdot}\ 10^{-10}N$

The numbers of c.c. of potassium iodide and cadmium sulphate refer, respectively, to 2*N* and 0·5*N* solutions.—J. F. S.

Volumetric analysis; New physicochemical method of ——, applied to some problems of inorganic chemistry. P. Dutoit and E. Grobet. J. Phys. Chim., 1922, **19**, 324—327.

A method is described by which solutions of acids may be titrated with bases using a thermometer graduated in 0·01° C. as indicator. The solution to be titrated is placed in a small Dewar vessel, which stands in a larger Dewar vessel; a mechanical stirrer is placed in the solution and the alkali added at regular intervals in amounts which cause the temperature to increase by not more than 0·02° C. The burette is wrapped in asbestos paper and the stopcock operated by a long pair of pincers. The number of c.c. of alkali added is plotted as abscissæ and the temperatures after successive additions as ordinates. The end point is marked by a decided change of direction of the curve. Not only is this point fixed by the curve, but all other points at which a change in the nature of the reaction occurs are fixed. Thus with sulphuric acid the points corresponding with the completion of the formation of the bisulphate and the normal sulphate are both accurately shown. In the titration of phosphoric acid with sodium hydroxide the points where the formation of NaH_2PO_4, Na_2HPO_4, and Na_3PO_4, respectively, is complete are well marked. In the titration of normal sodium phosphate with nitric acid the points where the formation of NaH_2PO_4, Na_2HPO_4, and H_3PO_4 is complete are clearly marked. The titration of the nitrates of zinc, lead, and magnesium with alkali by this method indicates the completion of the formation of definite basic salts and in the case of the two first-named metals, of zincates and plumbites, respectively. Titration of salts of cobalt, copper, and nickel with ammonia in the same way indicates the formation of the various ammonia complexes. This method yields identical results with those obtained by electrometric and conductivity titrations, and in addition it also indicates the formation of derivatives which these methods do not.—J. F. S.

Resorcinol; Application of —— in qualitative inorganic analysis. Lavoye. J. Pharm. Belg., 1921, **3**, 889—890. Chem. Zentr., 1922, **93**, II., 1154.

Characteristic colours are produced by mixing 1 c.c. of very dilute solutions of the following metals with 1 c.c. of 10% resorcinol solution and 2 c.c. of 10% ammonia solution, heating for a short time, and allowing the mixture to stand: Zinc, yellow-green, then dark blue; cadmium, a less intense blue; manganese in presence of ammonium salts, blue-green; nickel, blue-green; cobalt, red-violet, then blue-violet; copper, blue; platinum, garnet red; mercury, no colour but crystalline precipitate on evaporation. Acids turn all the solutions red. —A. R. P.

Uranium; Estimation of —— in presence of phosphoric acid. A. Schoep and W. Steinkuhler. Bull. Soc. Chim. Belg., 1922, **31**, 156—159.

Previous methods having proved unsatisfactory, the following is recommended: Silica and the elements which are precipitated in acid solution by hydrogen sulphide are first separated. The filtrate is freed from hydrogen sulphide by boiling and uranium oxidised by a few drops of nitric acid. The phosphoric acid is then precipitated by molybdate solution, and, in the absence of chlorides etc., this serves as a means of estimating phosphate. Ammonia is then added in slight excess and the solution gently heated, but not allowed to boil, after which ammonium sulphide is added until the liquid turns blood-red. After 20 mins. on the water bath a brown precipitate of uranium sulphide is produced, and when this has become black and granular heating is stopped. The precipitate is washed with warm dilute ammonium sulphide to which a few drops of ammonia have been added, the washing being continued until the washings no longer give a molybdenum reaction. If the operation has been carried out properly there is no need to dissolve and re-precipitate the uranium sulphide.—H. J. E.

Water; Estimation of —— by the apparatus of Meihuizen. K. Mohs. Woch. Brau., 1922, **39**, 139—141.

Tests with Meihuizen's drying apparatus (E.P. 114,620; J., 1918, 357 A) are described. Using steam heat and maintaining a temperature of 99° C., the moisture-content of flours, starches, etc., may be determined by heating for 50—60 mins. If xylol is used in place of water a drying temperature of 139° C. can be maintained and heating for 15—25 mins. is sufficient.—A. G. P.

Patents.

Gas calorimeters; Recording and integrating ——. The Secretary of the Board of Trade, and C. V. Boys. E.P. 180,080, 24.2.21.

In a recording gas calorimeter of the water-flow type the rate of flow of water is adjusted accurately to a predetermined value by trapping a stream of water in a vessel which is tipped and drained at regular intervals, the tipping being effected by the trapped water. While the vessel is tipped the stream of incoming water is delivered to a water-wheel or similar device driving the gas-controlling mechanism. The gas is delivered to a wet gas meter of which the drum is rotated on a screwed spindle by gas pressure independently of the driven spindle, so that longitudinal movement of the drum is produced by relative rotation of the drum and spindle, and this longitudinal movement operates a control for the gas inlet. The rate of gas delivery to the burner of the calorimeter is maintained at a constant value (measured under standard conditions of temperature and pressure) irrespective of changes of temperature and pressure by automatic variation of the liquid level in the meter in accordance with changes of temperature and pressure. The gas is saturated with water vapour. The calorimeter proper comprises a combustion circuit and heat interchanger, each of which is readily removable and replaceable. It includes a hot operative thermometer chamber and a cold operative thermometer chamber. An operating lever co-operates with both chambers so as to magnify the differential movement of the chambers in an inverse ratio to the relative linear movements of the individual chambers, with common temperature rise but in opposite directions. A recording arm is supported upon a lantern capable of rocking about a vertical axis, and mechanism is provided for integrating the departure of the recording arm from a predetermined position.—J. S. G. T.

Distilling apparatus [; Laboratory ——]. P. Anders and P. M. Ginnings. U.S.P. 1,418,691, 6.6.22. Appl., 25.2.21.

The upper end of the main column of a distilling head is closed by a stopper, and the side outlet tube projects inwards approximately to the centre of the column, the end of the projecting part being provided with a circular lip.—J. S. G. T.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

IV.—COLOURING MATTERS AND DYES.

Applications.

Durand & Huguenin Soc. Anon. Manufacture of mordant-dyeing colouring matters. 17,699 June 27. (Fr., 15.7.21.)

Scottish Dyes, Ltd., and Thomas. Manufacture of dyestuff intermediates. 18,804. July 8.

Complete Specifications Accepted.

35,647 (1920) and 21,708 (1921). Green, Saunders, and British Dyestuffs Corp. Manufacture of soluble acid colouring matters and intermediate compounds. (181,750.) July 5.

16,368 (1921). Durand & Huguenin A.-G. Manufacture of halogen derivatives of basic acridine dyestuffs. (165,721.) July 5.

22,991 (1921). British Dyestuffs Corp., Green, Saunders, and Adams. Manufacture of colouring-matters. (182,031.) July 5.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreaper. Manufacture of artificial silk etc. 18,174. July 3.

Dreyfus. Manufacture of artificial textile products. 18,560. July 6.

Johns-Manville, Inc., and Walsh. Drying and carbonising fabrics. 18,684. July 7.

Nitrogen Corp. Cellulose solutions. 18,149 and 18,150. July 1. (U.S., 2.7 and 21.11.21.)

Nitrogen Corp. Method of making cellulose compounds. 18,151. July 1. (U.S., 23.12.21.)

Rheinisch Westfälische Sprengstoff A.-G., and Seyfferth. Manufacture of radioactive plastic compositions from cellon, celluloid, etc. 17,823. June 28.

Complete Specifications Accepted.

2598 (1921). Dreaper. Manufacture of artificial silk etc. (181,758.) July 5.

8685 (1921). Dreyfus. Manufacture of artificial silk etc. (182,166.) July 12.

11,766 (1921). Courtaulds, Ltd., and Callimachi. Manufacture of threads, filaments, strips, or films of cellulose. (181,900.) July 5.

11,769 (1921). Courtaulds, Ltd., and Hegan. Manufacture of threads, films, etc. of cellulose. (181,901.) July 5.

11,770 (1921). Courtaulds, Ltd., and Wilson. Manufacture of coloured threads, filaments, strips, or films of cellulose. (181,902.) July 5.

30,466 (1921). Jentgen. Production of artificial threads, films, etc. from viscose. (171,691.) July 5.

1036 (1922). Claessen. Manufacture of waterproof material. (174,588.) July 12.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Blicquy and Callebaut. Dyeing-machines. 18,187. July 3.

British Alizaran Co., Dawson, Harley, and Nichol. Discharging agents and processes employing same. 18,522. July 12.

Geigy Soc. Anon., and Lüttin. Solutions for dyeing and printing fabrics etc. 18,696. July 7.

Geigy Soc. Anon. Process of dyeing or printing fabrics etc. 18,697. July 7. (Ger., 29.7.21.)

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Coote and others. 18,716. *See* II.

Freeth and Munro. Production of ammonium chloride and sodium carbonate. 18,758. July 8.

Ges. f. Kohlentechnik. 18,489. *See* II.

Guggenheim Bros. Leaching caliche and recovering nitrate. 18,460. July 5. (U.S., 7.11.21.)

Soc. d'Etudes Chimiques pour l'Industrie. Employing residues from decomposition of calcium cyanamide by acid. 17,544. June 26. (Switz., 25.6.21.)

Teillard. Purification of sulphate of baryta etc. 18,576. July 6. (Fr., 18.7.21.)

Threlfall. Manufacture of phosphorus pentoxide. 18,589. July 6.

Topp. 18,732. *See* XIII.

Westermann. Manufacture of pure sodium chloride. 17,760. June 28.

Complete Specifications Accepted.

35,720 (1920). Nitrogen Corp. Synthesis of ammonia. (155,592.) July 5.

36,516 (1920). Aluminum Co. of America. Manufacture of aluminium chloride. (163,975.) July 12.

5626 (1921). Dutt and Dutt. Preparation of titanium dioxide from bauxite. (181,775.) July 5.

10,482 (1921). Ebbw Vale Steel, Iron, and Coal Co., and Thickins. Manufacture of dry neutral sulphate of ammonia. (181,884.) July 5.

13,812 (1921). Nitrogen Corp. Preparation of hydrogen and ammonia. (163,323.) July 5.

17,574 (1921). Hunt. Recovery of sulphur, sulphides, etc. from a condition of emulsion. (181,984.) July 5.

13,444 (1921). Courtaulds, Ltd., and Jones. Separation of sodium carbonate from liquors or solutions containing caustic soda. (182,411.) July 12.

VIII.—GLASS; CERAMICS.

Applications.

Deutsch-Englische Quarzschmelze Ges., and Hirschberg. Manufacture of quartz etc. articles impervious to gases. 17,576. June 26. (Ger., 7.7.21.)

Rowart. Manufacture of sheet glass. 18,491. July 5. (Belg., 11.7.21.)

Soissan. Enamelling metals, wires, etc. 18,189. July 3. (Fr., 5.7.21.)

Complete Specification Accepted.

24,531 (1921). Westinghouse Lamp Co. Manufacture of glass. (170,563.) July 12.

IX.—BUILDING MATERIALS.

Applications.

Cuckow. Treatment of building materials. 18,137. July 1.

Gunn. Preserving and colouring brick, stone, etc. 17,993. June 30.

Riedel. Manufacture of hydraulic binding agents. 18,717. July 1.

*Wray. Composition for making bricks. 18,541. July 6.

Complete Specifications Accepted.

8408 (1921). Merz and McLellan, and Weeks. Cement manufacture. (181,811.) July 5.

9482 (1921). Schneider. Coating natural and artificial stone. (182,213.) July 12.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Adam and Davies. Detinning tinned iron scrap. 18,496. July 5.

Angell and Williams. Coating iron, steel, etc. with non-corrosive surface. 17,676. June 27.

Baker and Crawford. Composition for silver-plating metal. 18,771. July 8.

Chem. Fabr. Griesheim-Elektron. Casting oxidisable metals. 18,503. July 5. (Ger., 27.10.21.)

Dony and Spirlet. Concentrating iron ores. 17,849. June 28.

Gillespie, and Metallisation, Ltd. Protecting metal articles subjected to high temperatures. 17,649. June 27.

Jones, and Steel-Nickel Process Synd. Coating metals. 18,146. July 1.

Jones. Deposition of metals and alloys. 18,545. July 6.

Kubo. Manufacture of malleable cast iron. 17,632. June 27.

Kuehnrich. Manufacture of steel. 18,105. July 1.

Levoz. Cupola furnaces. 17,715. June 27. (Belg., 18.10.21.)

Saltrick. Iron and steel. 18,008. June 30.

Saltrick. Alloys. 18,009 and 18,010. June 30.

Ziegler. Operating melting and reducing furnaces. 18,464. July 5. (Austria, 5.7.21.)

Complete Specifications Accepted.

5759 (1921). Jackson (Leadizing Co.). Coating iron or steel articles with lead. (181,781.) July 5.

8529 (1921). Pacz. Production of alloys. (160,426.) July 5.

8705 (1921). Gillespie and Buckley. Manufacture of metallic powders. (181,831.) July 5.

8858 (1921). Pearson, Craig, and Durelco, Ltd. Reduction of oxides of tungsten and molybdenum. (181,837.) July 5.

9734 (1921). Wellman-Smith-Owen Eng. Corp., and Kemp. Furnaces for metallurgical etc. purposes. (181,863.) July 5.

9909 (1921). A.-G. Brown, Boveri u. Co. Electrically-heated muffle furnaces. (181,875.) July 5.

12,391 (1921). Hibbard. Metallurgical furnaces. (162,624.) July 5.

32,866 (1921). Miami Metals Co. Open-hearth furnaces. (182,399.) July 12.

XI.—ELECTRO-CHEMISTRY.

Applications.

Armstrong. Electrically-heated furnaces. 18,278. July 4.

Baum, and Chem. Fabr. Weissenstein. Anodes for forming per-compounds. 18,740. July 7.

John. Electrolytic apparatus. 17,684. June 27.

Kuehnrich. Electric furnaces. 18,106. July 1.

Lodge-Cottrell, Ltd. (Anderson). Electrical precipitation of suspended particles from gases. 18,028. June 30.

Oldham and Oldham. Galvanic batteries. 17,734. June 27.

Complete Specifications Accepted.

9131–2 (1921). Plauson. Carrying out electrochemical reactions. (181,848–9.) July 5.

9322 (1921). Aron. Electric dry battery cells. (160,807.) July 12.

9909 (1921). A.-G. Brown, Boveri u. Co. *See* X.

XII.—FATS; OILS; WAXES.

Applications.

Hodgkinson and Ridge. Purifying oils etc. 17,585. June 26.

MacIlwaine. Extraction of oil by volatile solvents. 18,595. July 6.

Complete Specifications Accepted.

8881 (1921). Schueler. Oil or like presses. (182,171.) July 12.

13,114 (1921). Pineger. Detergent. (181,923.) July 5.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Consort. f. Elektrochem. Ind. Improving artificial resins. 18,479. July 5. (Ger., 12.8.21.)

Jackson (American Cotton Oil Co.). Pigments and pigment compositions. 17,728. June 27.

Petroff. Production of phenol-aldehyde condensation products. 18,712–3. July 7.

Smith. Mills for grinding paints, inks, etc. 18,333. July 4.

Topp. Production of lead compounds and manufacture of paints etc. 18,732. July 7.

Wuyts. Preparation of artificial resins and oleoresins. 17,956. June 29.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Dunlop Rubber Co., Thomas, and Twiss. Vulcanisation of rubber etc. 17,995. June 30.

Jackson (Morgan and Wright). Manufacture of vulcanised rubber etc. 17,959. June 29.

Stevens (Firestone Tire and Rubber Co.). Drying rubber. 17,923. June 29.

Complete Specification Accepted.

8313 (1921). Wheatley, and Victoria Rubber Co. Heat-vulcanisation of rubber. (181,802.) July 5.

XV.—LEATHER; BONE; HORN; GLUE.

Complete Specifications Accepted.

9762 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of glue. (181,865.) July 5.

10,775 (1921). Richter. Depilation of hides and skins. (182,240.) July 12.

14,654 (1921). Glover and Martin. Preparation of a tanning agent for chrome tanning. (182,289.) July 12.

XVI.—SOILS; FERTILISERS.

Application.

Brewer. Fertilisers and production thereof. 18,204. July 3.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Guthrie, and McEwan and Co. Treatment of beer, stout, and liquid by-products from manufacture thereof. 18,136. July 1.

Harris. Production of alcohol. 18,482. July 5.

Complete Specification Accepted.

9361 (1922). Wade (Schneible). Distilling alcoholic and other liquids. (182,069.) July 5.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Plauson's (Parent Co.), Ltd. (Plauson). Preserving foods etc. 17,757. June 28.

Treble (Vakil). Manufacture of substitute for butter or ghee. 18,591. July 6.

Complete Specifications Accepted.

6624, 7576, and 9086 (1920). Watson, Jones, and Woodlands, Ltd. Manufacture of bread. (182,140.) July 12.

9485 (1921). Piqué, and Imperial Trust. Cooling and freezing fish etc. (182,214.) July 12.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Bloxam (Chem. Fabr. Griesheim - Elektron). Manufacture of aryl esters of phosphoric acid. 17,720. June 27.

Eckert. Oxidising aromatic compounds. 18,075. June 30. (Ger., 2.7.21.)

Imray (Soc. Chem. Ind. in Basle). Manufacture of aryloxynaphthylketones. 18,074. June 30.

Johnson (Elektrizitätswerk Lonza). Manufacture of metaldehyde. 17,806. June 28.

Complete Specifications Accepted.

8825 (1921). Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of liquid esters of phosphoric acid. (181,835.) July 5.

18,731 (1921). Johnson (Badische Anilin u. Soda Fabr.). Manufacture of urea. (182,331.) July 12.

21,455 (1921). Soc. Chim. de la Grande-Paroisse. Preparation of aromatic aminonitro-compounds. (169,688.) July 12.

XXI.—PHOTOGRAHIC MATERIALS AND PROCESSES.

Applications.

Cohen. Transferring photographs to fabrics, paper, etc. 17,682. June 27.

Diernhofer. Production of transparencies for projecting photographs in natural colours. 17,730. June 27. (Ger., 28.6.21.)

Hochstetter. Photographic mediums. 17,851—2. June 28.

Landau and Landau. Photographic processes. 18,311. July 4.

Complete Specifications Accepted.

8695 (1921). Obergassner. Production of opaque photographs in natural colours. (182,167.) July 12.

XXII.—EXPLOSIVES; MATCHES.

Applications.

Bash. Matches. 18,259. July 4.

Rathsburg. Initial priming-compositions and their manufacture. 17,952. June 29. (Ger., 4.11.21.)

Rathsburg. Manufacture of priming-compositions. 18,060. June 30.

XXIII.—ANALYSIS.

Application.

Slater. Estimation of small quantities of substances in gases or liquids. 18,523. July 6.

I.—GENERAL; PLANT; MACHINERY.

Molal entropy of vaporisation as a means of determination of heats of vaporisation. W. K. Lewis and H. C. Weber. J. Ind. Eng. Chem., 1922, 14, 485—486.

Using Hildebrand's statement (J. Amer. Chem. Soc., 1915, 37, 970) that the molal entropies of vaporisation of all liquids are nearly the same when compared at identical values of vapour concentration, the authors have devised a method of graphing which they consider more useful than the original method. In this method the ratio of the molal heat of vaporisation to the absolute temperature at which vaporisation takes place is plotted as the ordinate of the curve, whilst the abscissa is the pressure in atmospheres at which vaporisation takes place multiplied by 1000 and divided by the absolute temperature. The data include a list of substances of boiling point ranging from that of liquid hydrogen to that of boiling cadmium and zinc, but the authors have limited the pressures to one atmosphere or less, since the heats of vaporisation at greater pressures are seldom required.—S. G. U.

Rectifying columns for binary mixtures; Efficiency and design of ——. W. K. Lewis. J. Ind. Eng. Chem., 1922, 14, 492—497.

On the assumptions (1) that the column is so large that its surface is small compared with the amount of vapour passing through it, or that the column is so lagged that the heat lost through the sides is negligible compared with the heat passing through the column, (2) that the condensation of a mole of the constituent of higher boiling point from the vapour evolves sufficient heat to evaporate one mole of the constituent of lower boiling point from the liquid, the following basic equations of general applicability have been derived:—

$$dx/dn = y_n - x_n - V_c\ (y_c - y_n)/O_{n+1}$$

The integration of this equation will give the number of plates required with perfect rectification to enrich from x_1 to x_2, *i.e.*,

$$\Delta n = \int_{x_1}^{x_2} \frac{dx}{y_n - x_n - V_c\ (y_c - y_n)/O_{n+1}}$$

In a similar manner the number of plates below the feed plate for perfect rectification is given by

$$\Delta m = \int_{x_1}^{x_2} \frac{dx}{y_m - x_m - (O_f - V_c)\ (y_m - x_w)/(O_f + O_{n+1})}$$

where dn/dx = rate of increase of concentration of liquid per plate; y_n = mole fraction of more volatile component in the vapour V_n; V_n = vapour passing from plate n to plate $n+1$; x_n = mole fraction of more volatile constituent in plate n; V_c = moles of distillate produced per unit time; O_{n+1} = moles of overflow from plate $n+1$; y_c = mole fraction of more volatile component in distillate produced; y_n = mole fraction of more volatile component in vapour V_m; x_w = mole fraction of more volatile component in waste liquor; O_f = moles of mixture fed to the column per unit time. By means of these equations, when the terminal conditions and the amount of overflow are known, it is possible to calculate the theoretical rate of rectification within the column. As, however, the above assumptions do not hold in practice, the actual number of plates will differ from the theoretical number calculated from the above formulæ. The ratio of the actual number of plates to the theoretical number of plates is termed the plate efficiency of the column. This efficiency will depend upon type of plate and rate of flow of vapour and of reflux. If, therefore, the influence of these factors upon the plate efficiency is experimentally determined, the above equations can be safely used in problems of column design. An example is given showing how the formulæ can be used in the design of a column to determine the minimum overflow, the best practical overflow, the number of plates required, and the point of introduction of the feed. —S. G. U.

Heats of vaporisation; Determination of —— *from vapour pressure data.* W. K. Lewis and H. C. Weber. J. Ind. Eng. Chem., 1922, 14, 486—487.

Owing to the great curvature of vapour-pressure curves, difficulty arises in accurate interpolation when only a few points are known. This difficulty is overcome by adopting a method, developed by Johnston (Z. physikal. Chem., 1908, 62, 336), of plotting a temperature/temperature graph instead of a temperature/vapour pressure graph. The second temperature is the temperature of another liquid, termed the reference liquid, when its vapour pressure equals the vapour pressure of the first liquid. The resulting curve is very flat, often sufficiently so to be considered as a straight line over a wide range of temperature. Assuming that both vapours obey the gas laws, Clausius' equation is now applied, which gives $dp/pdT = L/RT^2$ for the original liquid, and $dp_w/p_w dT_w = L_w/RT_w{}^2$ for the reference liquid. Since $p = p_w$ and $dp = dp_w$, these on division give $dT_w/dT = L/L_w \times (T_w/T)^2$, from which L can be found, since dT_w/dT can be easily determined, since it is the slope of the T_w/T graph, which is practically a straight line. As this method depends upon the vapour pressures obeying the gas laws, it is only applicable with pressures at or below one atmosphere. (Note: p = vapour pressure of liquid under discussion; L = molal heat of vaporisation; T is the gas constant; and R the absolute temperature in ° C.)—S. G. U.

Plate efficiency of alcohol still. Robinson. *See* XVIII.

Patents.

Distillation; Apparatus for fractional ——. E. A. R. Chenard. E.P. 156,218, 3.1.21. Conv., 3.1.20.

The column constituted by concentric pipes in the apparatus of E.P. 130,992 (J., 1920, 92 a) is replaced by a rectifying column, and a large purifier is provided between the still and the column or between the distilling and the rectifying columns, according as the apparatus is discontinuous or continuous. Around each drip pipe in the rectifying column is provided a cylinder, open above and below, and so adjusted as to admit liquid, from below only, into the space between the cylinder, the bottom wall, and the level discharge pipe. The semi-adiabatic condenser is combined with the column in such a manner that the condensed products are systematically returned to the column compartments, the richer the condensed liquid the higher being the compartment to which it is returned. A filter or steam-trap formed of wire gauze strip, tightly rolled into a spiral around a closed tube, is provided at the outlet of each compartment of the rectifying column to retain liquid carried over by the vapours.—H. H.

Distilling, concentrating, or drying apparatus. T. Rigby. E.P. 180,963, 24.12.20 and 26.5.21.

Upright rotary drums, heated internally by vapour, are so grouped within a casing as to leave a central passage for the flow of vapour generated from the material. A liquid to be distilled or concentrated is caused to flow down the outer surfaces of the drums. Material to be dried is fed to the gaps between pairs of adjacent drums and is thus spread as a film on the drum surfaces. Above and below the drums vapour spaces partitioned off within the casing communicate with the interiors of the drums through hollow spindles each mounted in a vapour-tight gland in the partition, and the driving-mechanism is enclosed in the lower vapour space. Incrustration or scale or dried material is removed from the drums by scrapers. Each partition is connected with the adjacent upper or lower end of the casing by a duct into which passes the evolved vapour or the dried or concentrated material. The apparatus is applicable for carrying out the process described in E.P. 181,035 (*cf. infra*), and when constituting a unit of a multiple-effect dryer, its heating vapour inlet is fitted with an automatic throttle for ensuring predetermined temperature differences between the units. The material may be spread on the drums by the coaction with each drum surface of a second rotary member of different radius of curvature and/or different peripheral speed.—H. H.

Drying of peat or similar material. T. Rigby. E.P. 181,035, 7.12.20, 24.12.20, and 18.1.21.

Peat or the like is dried, or a solution or suspension of solid matter in a liquid evaporated to dryness, by feeding it in thin films on to the external surfaces of vertical rotary drying drums grouped together in the vapour spaces of drying units arranged in multiple effect. The material is fed into the bite of pairs of such drums revolving in opposite directions, the dried product being continuously scraped off. The material may be subjected to preliminary filtration or settling before treatment in the evaporator. The water of condensation from the heating surface of one effect passes to another effect at a lower pressure, under such control as to allow of the flashing off of steam, which is added to the vapour evolved from the material and is passed therewith into the heating vapour space of the next effect. The dried material may be cooled recuperatively by placing it in communication with a heating vapour space where a lower pressure prevails than that in the space where the material was dried. The rates, and extent of drying in each separate effect are controlled independently, and the products from the separate chambers may be either mixed or removed separately. The sensible heat of the non-condensable gases is recovered and added to that of the heating medium in subsequent stages. Undue fluctuations in temperature difference in the series of effects are avoided by an automatic vapour control throttle.—A. R. M.

Evaporating liquids; Process for ——. L. H. A. Bohrmann. E.P. 181,406, 10.12.20.

The liquid mixture to be evaporated is sprayed or atomised on to or under another liquid maintained at a temperature much above the boiling point of the constituent which is to be evaporated. The two liquids may either mix completely (*e.g.*, weak caustic soda may be sprayed into strong caustic soda) or form an emulsion (*e.g.*, an aqueous solution of salt may be sprayed into hot oil).—B. M. V.

Evaporating apparatus; Means for controlling the level of liquids in ——. W. H. P. Creighton. U.S.P. 1,419,824, 13.6.22. Appl., 31.12.20.

The level of the liquid within a vessel under steam pressure is maintained by an overflow device such as an inverted U-tube which is also connected with the steam space so as to be under the same steam pressure as the interior of the vessel, its height being adjusted by rocking or rotating it in a vertical plane.—B. M. V.

Still. S. E. Oliver. U.S.P. 1,419,894, 13.6.22. Appl., 6.5.20.

A dome-shaped cover, fitted with an internal and an external gutter which completely encircle the cover at its lowest point, is fixed to the top flange of the still. The cooling medium is sprayed over the upper part of the dome, runs down the outer surface and is collected in the outer gutter. The vapour from the still condensed on the inner surface of the cover is collected in the internal gutter, which is connected by a pipe with a receiver to which the distillate passes.—S. G. U.

Drying solid substances; Apparatus for use in ——. N. S. Kilner. E.P. 180,023, 14.2.21.

Attached to the inner surface of a vertical cylindrical casing are several layers of horizontal shelves, one edge of each shelf being inclined downwards at an angle of 30°—45° so as to act as a guide to the rising currents of hot air. Each layer consists of a number of shelves, so arranged that the discharging edge of each shelf is directly over the horizontal portion of a corresponding shelf on the layer underneath. Above the top layer of shelves are a number of bars performing the double function of distributing the material on to the shelves and supporting a central boss, in which rotates a shaft carrying a number of radial arms which scrape the material off the shelves, thus causing it to fall through a current of air on to the shelves below. Bolted to the upper flange of the cylinder is a conical casing provided at the top with a ventilator for the removal of the air. Coaxial with the casing is a small vertical shaft carrying a disc and a series of arms which rotate inside an inverted conical hopper. A horizontal shaft fitted as a screw conveyor, working in a trough, drives through bevel gearing this small vertical shaft and conveys the material into the conical hopper from which it passes to the rotating plate; it is thrown outwards from the plate on to the fixed arms and thence drops on to the first layer of shelves. —S. G. U.

Drying apparatus. D. J. Watrous, Assr. to Airdry Corp. U.S.P. 1,419,707, 13.6.22. Appl., 21.7.20.

A series of nozzles are so arranged that they can be individually rotated so that their axes point in any direction within a limiting angle of about 180°. Each of these nozzles is connected through its own valve with a compressed air supply pipe, and is fitted with an electric heating coil to warm the air as it passes through the nozzle. The valves are operated by spindles attached to hand-operated levers held in the open position by means of pins, upon the removal of which the valves are automatically closed by springs. The spindles also carry a device for operating an electric switch, so arranged that on opening the valve the switch is closed and a current flows through the heating coil of that particular nozzle, but on closing the valve this switch is opened and the current cut off from the heating coil.—S. G. U.

Drying machine. J. G. Bassette, Assr to Airdry Corp. U.S.P. 1,419,712, 13.6.22. Appl., 21.7.20.

The casing of a fan is supported by two large trunnion bearings in one of which the motor required for driving the impeller is housed. The other trunnion acts as the suction pipe of the fan and is fitted with an electric heater. The fan casing is provided with a nozzle through which the heated air is discharged, and a rib which extends partly round the casing, forming a friction surface concentric with the axis of rotation of the casing, and upon which a shoe is pressed by a spring. This rib terminates in a cam at one end and a shoulder stop at the other.—S. G. U.

Desiccator [for liquids]. H. B. Faber and W. H. Harding, jun., Assrs. to Atomised Products Corp. U.S.P. 1,419,664, 13.6.22. Appl., 26.3.17.

The liquid to be desiccated is sprayed into a current of heated air in a tower and the moist hot air and entrained solids are passed through two "condensers," the first of which condenses some moisture upon the entrained solid particles and delivers both to the supply tank; the second condenser contains a coil through which the liquid from the supply tank is circulated and is preheated by the heat in the saturated air after it has been freed from solids.—B. M. V.

Drying apparatus. C. H. Brown and A. A. Coldrey. E.P. 181,082, 2.3.21.

The patent relates to mechanical improvements in apparatus of the type in which articles to be dried are carried through a drying chamber by a conveyor.

Scrubber. W. G. Laird, Assr. to H. L. Doherty. U.S.P. 1,419,867, 13.6.22. Appl., 6.9.16.

The scrubber is made up of a number of flanged sections bolted together, the bottom section being provided with a gas inlet and liquor outlet, whilst the top section is fitted with a liquor inlet and a gas outlet. Each of the intermediate sections is fitted internally with a channel which increases in depth towards one end. Sloping perforated trays having holes sufficiently small to prevent the downward passage of the liquid whilst gas is passing upwards through the perforations, cover the space bounded by the inner edges of these channels. The vertical edges of these trays dip into the channels, thus forming a seal preventing the passage of the gas between the edges of the trays and the sides of the apparatus. The trays slope alternately from left to right and right to left and a weir is provided for the overflow from the channel at the deepest section of the channel. This overflow is directed on to the highest point of the tray beneath, down which it flows to the deepest portion of the channel immediately below this tray. During its passage across the tray gas is bubbled through the liquid. The slope of these trays can be adjusted from outside whilst the plant is in operation.—S. G. U.

Separation or grading of powdered materials and the treatment thereof by air or other gases or vapours; Effecting the —— and apparatus to be employed therein. W. H. Reynolds, W. W. Dickin, and G. L. T. Kenyon. E.P. 181,560, 25.4.21.

The powdered material is sprinkled into the top of a tower and the finer or lighter material drawn off by an air current from about the middle of the tower, preferably by means of an internal axial pipe with slits or perforations in its circumference. —B. M. V.

Centrifugal separators. G. C. Barnes and J. R. Morgan. E.P. 159,217, 21.2.21. Conv., 19.2.20.

A conical frame is formed of two unequal discs joined by a series of screwed rods passing through holes drilled near their outer edges. To these rods are fixed blades so as to form a helix or spiral to assist in carrying the material from the narrow to the wide end. Another and slightly larger conical frame is made in the same manner, but using T-bars instead of screwed rods. Frames fitted with wire gauze are bolted between these bars, thus forming a conical wire gauze cage. To permit of the discharge of material too coarse to pass through the gauze, this does not extend up to the larger disc. These frames, placed one within the other, are mounted on ball bearings; those carrying the smaller frame run on a fixed horizontal shaft, whilst the second pair of ball bearings, running on sleeves projecting from the outer surfaces of the smaller pair of discs, support the discs used in the larger cage. The sleeve of the larger disc of the smaller frame is extended to carry the driving pulley; an extra ball bearing between the shaft and sleeve is fitted at the outer end. Rotation of the outer frame is effected through a train of spur wheels, worm and screw gear, and bevel wheels arranged at the driving end of the machine. The shaft round which these frames rotate is hollow and divided into two portions. At the end of this shaft, near the smaller end of the frames, a hopper with worm gear is fitted, the feed taking place through the hollow shaft, which is cut away underneath for this purpose. The point of distribution of the feed is regulated by a sliding plate operated by a rack and pinion. Two pipes enter the other portion of the hollow shaft from the driving end, and are used for the supply of media to wash or dry the material during its passage through the machine. The frames rotate within a housing so arranged that the material which passes through the gauze is discharged at the one end, whilst the coarse material is withdrawn at the other.—S. G. U.

Furnaces of steam boilers and other similar furnaces; Heating method applicable to the ——. C. Magnée and E. Demeure. E.P. 163,270, 11.5.21. Conv., 12.5.20.

The advantages resulting from the decomposition of carbon dioxide on contact with the coal in ignition are utilised. To obtain for this purpose a mixture in regulated proportions of air and inert products at the desired temperature, without using a superheater, a portion of the combustion products is sucked from the furnace by air under pressure. The air is injected into a mixing tube, connected at its upper part directly with the furnace and at its lower part with the ash-pit, and provided with means for regulating the supply of air and of the products recovered from the furnace.—H. H.

Furnaces. S. A. Sears and W. R. Twigg. E.P. 179,965, 11.11.20.

In a furnace with a double set of preheating chambers the lower portion of the preheater casing is divided into two by a central brick partition extending the full depth of the furnace. Horizontal tiles are built between the outer walls, and the partition thus sub-divides each half into a series of parallel chambers of rectangular cross-section extending the full depth of the furnace. The tiles have a series of holes near their edges into which are fitted a number of tubes in such a manner that the air entering the lowest chamber, No. 1, is led through one set of tubes past chamber No. 2 immediately overhead, and discharged into chamber No. 3, from which it passes through chambers Nos. 5 and 7, etc., to the preheater chamber. The gas enters chamber No. 2, flows past chamber No. 3 into chamber No. 4 and through No. 6 to the preheater chamber. Each of these chambers is fitted with tiles which cause the gas or air to flow across the chamber and back again before reaching the outlet tube. If the furnace is designed for regenerative working, each set of chambers terminates in a preheating chamber, half the breadth of the hearth, where the gas and air mix and then flow through ports on to the hearth. In the recuperative design of furnace two preheating chambers, placed one above the other and extending the full breadth of the hearth, are used, each chamber being connected with the hearth through its own set of ports. When working regeneratively the hot spent gases pass downwards through one set of chambers, while the gas and air travel upwards through the other set in the manner indicated above. The flow of spent gases, air, and gas can be directed and controlled by change-over valves. When working as a recuperative furnace the hot spent gases pass downward through the 6th, 4th, and 2nd chambers of one section, and the 7th, 5th, 3rd, and 1st chambers of the other section, the gas passing up the remaining chambers of the one section and the air up the remaining chambers of the other. By a different arrangement of piping the furnace can be adapted for regenerative and recuperative working. The furnace can also be built as a furnace with a single set of preheating chambers, and can be arranged for either regenerative or recuperative working. In this design only the air is heated, the gas being blown directly on to the hearth.—S. G. U.

Annealing kilns. B. Wallis. E.P. 180,944, 20.8.21.

In an annealing kiln the fire-grate is placed at the middle of the back wall and the entrance door at the front of the kiln or at the side of the main flue, so as to provide a stronger roof. Four short downcasts in the floor of the kiln are connected with the main flue at a central point.—A. B. S.

Cooling and liquefying air and other gases; Process and device for ——. Heylandt Ges. für Apparatebau m.b.H., and M. von Unruh. E.P. 167,144, 11.3.21. Conv., 28.7.20.

The patent relates to a process for liquefying air and other gases of the type in which high-pressure gas is divided into two portions, which are expanded with and without doing work respectively, and in which the exhaust from the expansion engine, together with any unliquefied gas remaining from the portion which is expanded without doing work, are used to cool the latter portion of the gas, before expansion, in a heat interchanger. The interchanger is provided with an extension in which the combined exhaust gases cool further both the incoming streams of high-pressure gas. The inlet valve of the expanding engine is entirely within the high-pressure conduit of the engine, thus avoiding leaks to the external air. It is opened by the piston just before the latter reaches dead centre, and is closed by the high-pressure air behind it as soon as the piston has moved far enough on the expansion stroke to permit this. To keep the clearance low the piston head and cylinder head are made frusto-conical.—B. M. V.

Precipitating dust from gases by electricity. Siemens-Schuckertwerke Ges.m.b.H. E.P. 170,601, 24.10.21. Conv., 22.10.20.

In a plant for precipitating dust from gases by the action of a rotary field, the brush-discharging electrodes are preferably of smaller superficial area than the others, and are composed of a number of rods surrounded by a separating electrode of large superficial area. The former are connected with the individual phases of a polyphase source of current of such high voltage that substantial quantities of electricity flow from the charged to the separating electrodes, the discharge producing a rotary field.—J. S. G. T.

Insulator for electrodes of electrical gas purifiers. The Lodge Fume Co., Ltd. From Metallbank u. Metallurgische Ges. A.-G. E.P. 181,284, 28.9.21.

An insulator for the electrodes of electrical gas purifiers is disposed in an arch or recess in the gas main, preferably in the gas intake, the opening of the recess being turned away from the gas current. The interior of the recess is accessible from outside through doors, and the gas-distributing surfaces form a casing for the insulators.—J. S. G. T.

Heat-transferring systems. T. Sugden and A. Hall. E.P. 179,258, 28.1.21.

A coil arranged as a superheater is coupled directly to the working coil, situated in the chamber or vessel to be heated. The outlet of the latter coil is connected to the inlet of a separator, the outlet of which is coupled to the suction of a centrifugal pump by means of which the working fluid is returned to the superheater coil. The working fluid can thus be circulated in a cycle a number of times, any condensed liquid being removed from the circuit through the separator. If steam is used the loss due to condensation is made up by connecting the plant through a reducing valve with a boiler.—S. G. U.

Pulverisers and crushing mills. F. G. Brettell. From Soc. Anon. Les Ateliers Réunis. E. P. 180,890, 25.5.21.

A series of hammers are arranged around the periphery of a rotating disc within a casing, the working faces of the hammers being of larger area than the rear ones. Radial vanes are provided on the side of the disc remote from the feed in order to assist in the pulverising and create a draught through the machine.—B. M. V.

Pulverising or grinding apparatus. The Powdered Fuel Plant Co., Ltd., Assees. of Soc. Anon. La Combustion Rationelle. E.P. 181,290, 20.10.21. Conv., 27.6.21.

The apparatus is constructed with a number of rings of closely spaced blades, similar to a steam turbine, except that the broader working faces of the blades are parallel to the shaft, the material being caused to travel longitudinally by a draught provided by a fan separate from or contained in the machine. A preliminary crushing device of known disintegrator type may be incorporated, and the "turbine" vanes may be so shaped as to be set in motion by air under pressure, which air will also convey the material through the machine.—B. M. V.

Grinding; Fine ——. H. M. Plaisted, Assr. to Williams Patent Crusher and Pulverizer Co. U.S.P. 1,418,735, 6.6.22. Appl., 21.3.19.

A series of hammers, the heads of which have convex inner and outer surfaces, are pivoted on a rotor which revolves inside a cylindrical chamber, the hammer heads being substantially tangential to the inner surface of the casing. The material to be ground is fed into the machine from a hopper placed so that its discharge is tangential to the chamber at a point on a level with the axis of the rotor. The finely ground material is discharged through a pipe placed well above, and on one side of the rotor, and having its axis parallel with the axis of the rotor. Provision is made for retaining the larger particles within the casing of the machine and returning them through passages formed by guide plates to the rotor chamber.—S. G. U.

Filter for wines, sugar liquors and the like. L. Tottereau. E.P. 180,935, 21.7.21.

The filter consists of a number of pockets of filter cloth attached by nipples to a collector formed by the double walls of the containing cylinder. The pockets are maintained in an expanded condition by means of woven cord. The liquor is filtered by passing from the outside to the inside of the pockets, which are washed by circulating a water current in the opposite direction.—A. G. P.

Filtration of colloidal matter from liquid mixtures; Vacuum ——. W. Mauss. E.P. 181,123, 8.3.21.

Colloidal deposit is detached from the surface of a vacuum filter leaf by a thin continuous sheet of water impinging at a slight inclination to the leaf surface at a very high velocity while the leaf and the nozzle through which the water is delivered are moved past one another. Slight air pressure may be set up during stripping to cause rucking of the filter fabric at the point of impact of the water. The leaves may be oscillated between a filter tank and a stripping tank, and means actuated from the oscillating shaft may be provided to bring the nozzles into operation as the leaves are being withdrawn from the stripping tank.—H. H.

Evaporator. H. W. Paulus, Assr. to Royal Baking Powder Co. U.S.P. 1,418,878, 6.6.22. Appl., 26.7.20.

The evaporator consists of a tank containing the liquor to be evaporated and a series of U-tubes immersed in the liquor. Means are provided for supporting the U-tubes.—T. A. S.

Catalytic processes involving gaseous or vapourous carbon compounds; Carrying out of ——. Chemical Fuel Co. of America, Assees. of E. W. Stevens. E.P. 160,466, 3.3.21. Conv., 18.3.20.

See U.S.P. 1,374,119 of 1921; J., 1921, 339 A. The process is applicable to the production of hydrogen from water-gas and steam and to the cracking of hydrocarbon oils in presence of a catalyst. The sparking is produced by placing the catalyst in circuit with a source of high-potential, rapidly oscillating alternating current.

Centrifugal decantation. W. Mauss, Assr. to Continuous Centrifugal Separators, Ltd. U.S.P. 1,419,285, 13.6.22. Appl., 19.2.20.

See E.P. 164,418 of 1920; J., 1921, 535 A.

Vacuum filter. W. Mauss, Assr. to Continuous Centrifugals, Ltd. U.S.P. 1,419,286, 13.6.22. Appl., 3.9.20.

See E.P. 176,395 of 1920; J., 1922, 315 A.

Heat interchangers. [*Air heaters.*] Merz and McLellan, E. G. Weeks, and H. H. Baker. E.P. 181,501, 16.3.21.

Filtration of liquids. E.P. 181,044. *See* XIXb.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Fundamental study of Japanese ——. C. Iwasaki. Tech. Rep. Tôhoku Imp. Univ., 1921, 2, 235—275.

In continuation of his previous work (J., 1920, 620 A), the author has investigated the physical properties of the South Sakhalin coals. The results of his analyses have been plotted on triangular diagrams, and it is shown that the moisture content of the coals is a good indication of their caking or non-caking character. Most of the coals are of low grade, but the author describes a cannel coal of a caking character, although the volatile matter is very high for a coal of this nature. The coals highest in moisture are the non-caking coals. Most of the Sakhalin coal consists of fundamental matter, and it belongs to the sapropelic species, whilst charcoal of a bulky variety occurs, which the author describes as differing entirely from the fusain of Stopes. This charcoal is supposed to have been produced by forest fires during the process of drift formation, and occurs mainly in the coal of the Noborippo group, in which the ash is very low. In general the ash content is inversely proportional to the moisture content, from which the author concludes that the water is an essential constituent of the "woody" matter. The original vegetation of the region differed from the present vegetation, since dicotyledon fossils have been found in the coal, whilst the present vegetation is coniferous. —A. G.

Coal; The oxidisability of —— and the determination of moisture. E. Mertens. Bull. Fed. Ind. Chim. Belg., 1922, 361—364.

A sample of fat coal weighing 3 g., ground to pass through a sieve of 4900 holes per sq. cm., was spread over the bottom of a dish of 4 cm. diameter and placed in a drying oven heated to 105° C. The dish was suspended by a fine non-oxidisable metal wire to the beam of a balance, the wire passing through the top of the drying oven so that the sample could be weighed without removal from the oven, and the oven was sufficiently remote from the balance to prevent any error due to heat. The coal sample was heated for a period of 1400 hours, and the results were plotted against time. Two curves are reproduced, one showing the total time of heating and the other being plotted for the first seven hours. The loss in weight occurred during the first quarter of an hour, after which period the sample steadily gained in weight, indicating that oxidation was taking place. Distillation with xylol gave approximately the same figure as heating for 15 minutes at 105° C. After heating for about 36 hours the weight of the sample was the same as at the beginning, the loss in weight of 1% due to evaporation of moisture having been counterbalanced by oxidation to this extent. At the end of 1400 hours there was an increase in weight of 5·97% on the original weight. The author recommends the determination of the moisture content of coals by the xylol distillation method, using a large quantity of coal, *e.g.*, 50 g., thus eliminating the error due to oxidation.—A. G.

Combustion; Temperatures of ——. J. Bronn. Z. angew. Chem., 1922, 35, 328.

The value of the temperature of combustion for hydrogen in pure oxygen given in the "Chemiker-Kalender," viz., 6670° C., corresponds to a value of 0·485 for the specific heat of steam, but this value for the specific heat is valid only for steam at a temperature of 800° C. If the value 0·85 be used for the specific heat at 4000° C. of steam (this value was obtained by extrapolation from published data for temperatures up to 3000° C.), the calculated temperature of combustion of hydrogen in oxygen is 3900° C. Other temperatures of combustion calculated in a similar manner are 5000° C. for carbon monoxide, 4400° C. for methane, and 6200° C. for acetylene, in oxygen; and 2260° C. for hydrogen, 2400° C. for carbon monoxide, 2070° C. for methane, and 2670° C. for acetylene, in air. Methane may be used with advantage for welding as it supplies a large amount of heat, whilst its temperature of combustion is not so high as to injure the metals operated on. The flame temperatures of gases are greatly influenced by the velocities of flame propagation. The velocities of flame propagation of ethylene, acetylene, and benzene differ.—H. M.

Benzene; Determination of —— in gases. A. Krieger. Chem.-Zeit., 1922, **46**, 468—469.

The method of determining benzene in distillation gases by absorption with activated charcoal (*cf.* Berl, J., 1921, 567 A) possesses many advantages over the petroleum oil absorption method, and is recommended for works' control. The petroleum method is, however, quite trustworthy; it is the more suitable for the determination of benzene when only a few litres of gas are available, and may be used for checking the accuracy of the charcoal method.—W. P. S.

Carbon monoxide and small quantities of combustible gases [hydrogen and methane]; Determination of ——. G. Wollers. Stahl u. Eisen, 1922, **42**, 1050—1053.

Carbon monoxide is only absorbed completely after at least two treatments with ammoniacal cuprous chloride, followed by a third treatment with a fresh solution. The absorption capacity of the solution is influenced by the presence of hydrogen, methane and other hydrocarbons; nitrogen has the least effect. Hence in the determination of carbon monoxide in, say, producer gas, it is desirable to remove the hydrocarbons as completely as possible. The author's method is first to dry the gas over calcium chloride and phosphorus pentoxide, condense out the hydrocarbons by cooling to −85° C., and finally cool to −190° C. The gas thus obtained is essentially carbon monoxide, nitrogen, and hydrogen. The absorption capacity of the ammoniacal cuprous chloride solution is also materially affected by the concentration of the carbon monoxide in the gas. In calculating the calorific value of producer gas, coke-oven gas, or coal gas from an analysis of the gas, results of sufficient accuracy are obtained by assuming that the heavy hydrocarbons are composed of $\frac{1}{5}$ benzol, $\frac{3}{5}$ ethylene, and $\frac{1}{5}$ propylene, and a mixture of such composition has a calorific value of approximately 18,500 cals. per cub. m. For the determination of hydrogen and methane combustion with copper oxide or combustion in a platinum capillary or by platinum wire in a quartz capillary gives more accurate results than the explosion method. A method of determining hydrogen by means of palladium black is also described.—J. B. F.

Bitumen; Attempted isolation of —— in its original form from bituminous rocks. E. Hentze. Z. angew. Chem., 1922, 35, 330—331.

Instead of the process of Narbutt (*cf.* J., 1922, 452 A), which consists in extracting the bitumen from the rock, the procedure used by the author consisted in dissolving the rock from the bitumen. Green kieselguhr and Esthonian oil shale or "kukkersite" were tested, the respective contents of bitumen being about 4% and 28%. Two kg. of each sample was repeatedly treated with dilute hydrochloric acid in the cold and washed with warm water for a period of 14 days to dissolve calcium and iron compounds. The kieselguhr was then treated for four weeks and the kukkersite for 14 days, first with dilute and then with 40% hydrofluoric acid to remove silica and clay. The residues were still not free from ash, and they were extracted with chloroform to obtain the bitumen free from inorganic matter. To compare the extracted bitumen with that present in the rock the extracts were mixed with clay and calcium carbonate to represent the composition of the original rock and distilled in a glass retort, as also were the original rocks. Isolated bitumen from kieselguhr gave 1% less, and the bitumen from kukkersite 5% less volatile products than the original bituminous rock, but the quantities of light-boiling products in the resulting tar were much higher in the isolated bitumens, and the cokes produced by the latter were richer in carbon. Polymerisation seems to have occurred in the extracted bitumens, followed by cracking on distillation. It is proposed to attempt the isolation of bitumens in an unchanged state by electro-osmotic separation from a colloidal suspension.—H. M.

Alcohol-petrol; Limit of inflammability of the vapours of the system —— and of a ternary system with a basis of alcohol and petrol. R. G. Boussu. Comptes rend., 1922, 175, 30—32.

A study of the variation of the lower limit of inflammability of the binary system alcohol-petrol and of the ternary system petrol-alcohol-ether, using the method of Le Chatelier and Boudouard (*cf.* J., 1898, 651, 652). The results verify the formula $n/N+n'/N'=1$, where N and N′ are the limits of inflammability of each of the two vapours and n and n' the proportions of each present in the mixture under examination.—W. G.

Hydrocarbons; Detonation characteristics of blends of aromatic and paraffin ——. T. Midgley, jun., and T. A. Boyd. J. Ind. Eng. Chem., 1922, 14, 589—593.

The effect of the addition of varying percentages of benzene, toluene, and xylene on the detonating or "knocking" tendencies of paraffin hydrocarbons when used as fuel in automobile engines was investigated, using as a standard of comparison paraffin fuels containing small amounts of xylidine, which in common with other aromatic amines exerts a powerful suppressing action on detonation. The relative intensities of different detonations were measured by means of a bouncing pin combined with the standard pressure element of the Midgley Indicator which is screwed into the combustion chamber of the engine. When detonation occurs the pin jumps upwards, and the fluctuations of the pin over a period of time were integrated by means of contact points in a circuit enclosing a sulphuric acid voltameter. The bouncing of the pin closed the points and the amount of gas evolved was measured and compared with that evolved by a fuel of similar "knocking" characteristics run immediately before and after it. The results are recorded in tables and curves, from which it appears that xylene is more effective than toluene, and toluene than benzene in suppressing detonation. The addition of a small percentage of aromatic hydrocarbon to the paraffin fuel has only a slight effect, but with 20% or more the effect increases rapidly, and if the concentration of the aromatic hydrocarbon is expressed as a molecular percentage, the effectiveness for suppressing detonation varies directly as the square of the concentration up to concentrations of 70%.
—G. F. M.

Floridin; The limits of the adsorptive receptivity of ——. M. A. Rakusin. Petroleum, 1922, 18, 797—798.

A 1% solution of Grozny petroleum free from paraffin was decolorised by standing with 5% of floridin (aluminium-magnesium hydrosilicate) for 24 hours, and formed a polarimetrically clear solution. A further addition of floridin did not improve the result. The same result was attained by the action of 1% of floridin for 96 hours. It is suggested that much smaller quantities of floridin would have the same effect if the time of contact were prolonged, and that its action resembles that of catalysts, or of the trypsins in digestion, in which the quantity of enzyme multiplied by the time of action is a constant.—H. M.

Solubility of hydrocarbons in liquid sulphur dioxide. Zerner and others. *See* III.

Patents.

Brown coals and peat; Process for improvement of inferior ——. K. W. J. H. Jacobs. E.P. 157,794, 10.1.21. Conv., 28.7.19.

The material is freed from water and the bulk of carbon dioxide by distillation. Heat is supplied to the material until the temperature reaches 250°—270° C., when an exothermic reaction begins, by the heat of which the distillation is continued. By this means, and the further application of heat, low-temperature tar is distilled off until a maximum temperature of about 350° C. is attained. The resulting residue is said to be a valuable long-flame fuel. Superheated steam not exceeding about 10% of the weight of the fuel may be admitted into the distillation vessel.—A. R. M.

Gas-coal substitute; Process for the production of a fuel capable of application as a ——. K. W. J. H. Jacobs. E.P. 157,795, 10.1.21. Conv., 28.7.19.

Brown coal, lignite, peat, or the like, after partial drying, is heated in a vessel capable of being closed, the heating being carried out with the outlet open until traces of low-temperature tar are carried over, whereupon the oultet is completely or nearly closed, so that the material is subjected to further external or spontaneous exothermic heating under pressure. The resulting product is a good quality semi-coke which may be used as a substitute for gas-coal.—A. R. M.

Combustion of gaseous fuel in furnaces; Means for effecting the ——. Soc. Anon. d'Exploit. des Brevets Cousin dite le Chauffage Industriel. E.P. 165,745, 30.6.21. Conv., 1.7.20.

A chamber packed with refractory chequerwork is interposed between the combustion space and the working space of a furnace. This chamber is of such depth that solid particles cannot fall into the working space, and its floor extends beyond the pile of chequerwork so that particles cannot fall into the combustion space. Doors are provided to facilitate replacement or re-arrangement of the chequerwork. Porous material may be added to secure surface combustion in the upper part of the chequerwork. —H. Hg.

Gas manufacture. G. Helps. E.P. (a) 181,403, (b) 181,404, and (c) 181,665, 10.12.20.

(a) Coal is treated in a combined gas-producer and retort to produce a rich gas, which is withdrawn from the top of the retort, and producer-gas which rises in an annular space around the retort and is then burnt in the top of a chamber surrounding an independent vertical retort. The products of combustion pass upwards through a similar chamber surrounding a retort containing coal at a lower temperature. The chambers are so interconnected that the producer-gas may be burnt alternately in either chamber according to which retort was last charged with coal. The volatile products from the low-temperature retort are passed into the retort around which producer-gas is burning at a point about one-third of its height from the top; all the products thus pass through the hottest zone before they are finally withdrawn from the retorts. A number of retorts may be arranged in conjunction with one producer and worked either in series or in parallel. Part of the producer-gas or some other hot, low-grade gas may be passed into the retorts and mixed with the coal-gas. (b) Producer-gas is passed intermittently through a vessel containing coke, which is heated to incandescence by the alternate admission of air. The heated gas then passes downwards through a vertical retort containing coal undergoing partial carbonisation and is thereby enriched. The waste gases produced by blowing air through the coke are passed through a chamber surrounding the retort, or the retort may be placed in the centre of the chamber containing the incandescent coke, in which case the waste gases pass direct to a chimney. (c) A number of retorts, each of which is in turn heated by the combustion of producer-gas, and the remainder of which are heated by waste gases as described above, are arranged in series.—H. Hg.

Gas producer; Convertible heating stove and ——. H. C. L. Holden, T. G. Tulloch, and D. J. Smith. E.P. 181,450, 8.3.21.

An anthracite stove of the slow-combustion type is provided with a branch pipe fitted with two throttle valves, so that when being used as a heating stove the products of combustion are passed up the chimney to waste, whilst when in use as a producer the producer-gas generated is deflected through another pipe to an internal-combustion engine, furnace, or the like. The grate is provided with an annulus containing water, the level of which can be adjusted externally, and which provides the steam for use in generating producer-gas. The grate can be rocked by a protruding arm, which effects removal of the ash and also stirs the fuel bed to produce better gasification. An annular boiler can be fitted as desired to utilise the heat of combustion of the anthracite.—A. G.

Hydrogen; Methods and apparatus for production of —— [*in coal carbonisation*]. Cumberland Coal Power and Chemicals, Ltd., J. H. West, and A. Jaques. E.P. 181,062, 9.2.21.

The gases evolved during the initial stages of the carbonisation of coal are passed together with steam over partially carbonised coal or coke at a temperature between 1000° C. and 1100° C., the carbonisation being effected at a rate sufficiently slow to allow of the decomposition of nearly all the hydrocarbon products in contact with the hot coke. Not only are the tarry vapours of condensable hydrocarbons decomposed, but also a high percentage of the so-called non-condensable gases, *e.g.*, ethylene and methane, whereby largely increased yields of hydrogen are obtained. The apparatus consists of a bank of six ovens arranged to work in pairs, the individual ovens of each pair being connected by means of detachable pipes (provided with steam jets) secured to the doors of the ovens so that the gases can pass from one oven through the other of the pair before passing into a common delivery conduit.—H. R. D.

Gas; Treatment [*cleansing and enriching*] *of* ——. T. G. Tulloch and D. J. Smith. E.P. 181,102, 4.3.21.

Gas from a producer is freed from suspended particles and simultaneously enriched by causing it to pass through a wall or screen of absorbent material, preferably arranged as a cylindrical wick which provides an enclosed chamber, closed at the bottom by a seal of oil or other enriching medium and at the top by a gas-tight casing, the inlet to the chamber being within it and the outlet from the apparatus being on the other side of the screen. A by-pass connexion, which may be wholly or partly closed by a valve, connects the inlet with the outlet outside the cleansing chamber. A constant oil level is provided by means of a float-feed chamber, and a sludge-cock or similar device provides means for running off the oil or deposited refuse from the inclined surfaces of the bottom of the apparatus. —A. R. M.

Acetylene gas; Materials for purifying ——. J. R. Booer, and The District Chemical Co., Ltd. E.P. 181,571, 9.5.21.

A basic purifying material is made by incorporating kieselguhr with a mixture of ferric chloride and ferric oxide, either dry or hydrated, and not more than 0·05% of mercuric chloride is added. After mixing, the material is left to stand for 2—12 months.—A. G.

Coal; Coking ——. F. Puening. U.S.P. 1,419,908, 13.6.22. Appl., 30.11.17.

A layer of the coal to be coked is placed between two hollow boxes, which are then heated internally. —A. G.

Separating oils [*from emulsions*]; *Process of* ——. Trent Process Corp., Assees. of W. E. Trent. E.P. 167,738, 13.4.21. Conv., 11.8.20.

The process is designed to deal with such emulsions as "base sediment," refining acids, and sludges.

When such emulsions are agitated with comminuted carbon, the oil and carbon unite, forming an agglomerate from which the water and the other substances separate. The carbon used is fine enough to pass through a 100- to 200-mesh sieve, and the quantity used is 2 lb. of carbon to 1 lb. of oil in the mixture. The oil-carbon mixture sinks in still water, and may be used direct as fuel or distilled to recover the oil.—T. A. S.

Fuel for internal combustion engines. A.-G. für Anilin-Fabr. E.P. 169,428, 17.6.21. Conv., 20.9.20.

The fuel consists of a mixture of hydronaphthalenes with suitable cyclohexanes, *e.g.*, a mixture of 50—70% of methylcyclohexane and 50—30% of tetrahydronaphthalene.—T. A. S.

Petroleum or other hydrocarbon oils; Process and apparatus for treating ——. J. P. Persch. E.P. 181,034, 6.12.20.

The oil is treated with a hot gaseous fluid, preferably air, in an apparatus so arranged that an injector effect is obtained, the oil being drawn from bulk, passed through tubes, mixed with the air, and returned to the bulk. In an example given, oil of 38° B. (sp. gr. 0·833) was treated for 30 mins. with compressed air at 390° F. (200° C.). The temperature of the oil did not exceed 152° F. (67° C.). After treatment, the oil yielded 60% of gasoline, 7% of lubricating oil, and 3% of heavy lubricating oil. The gasoline yield from the original oil was 25%. An oil of 11°—15° B. (sp. gr. 0·993—0·966), after treatment for 30 mins., was much less viscous and retained this property indefinitely. —T. A. S.

Hydrocarbon material; Process of making unsaturated ——. A. A. Wells, Assr. to S. B. Hunt. U.S.P. 1,418,414, 6.6.22. Appl., 9.10.16.

Hydrocarbon oils are cracked under high pressure until "still bottoms" of a tarry consistency are formed. These "still bottoms" are distilled, and the distillate cracked again, under a pressure lower by at least one atmosphere than the original cracking pressure. By this process hydrocarbon material is obtained rich in unsaturated hydrocarbons, which can be extracted with sulphuric acid without undue rise in temperature.—T. A. S.

Petroleum; Apparatus for treating ——. L. Clark. U.S.P. 1,418,621, 6.6.22. Appl., 14.3.18.

Oil is fractionated or cracked by heating in the presence of a heated fluid, *e.g.*, flue-gases. The heated gases cause circulation of the oil and carry away the vapour. The apparatus consists of a shell suspended in a chamber to provide an annular passageway. The bottom of the shell is an open cone. A central pipe conducts the heated gas down the shell and discharges it at the bottom of the cone, whence it rises in the annular space and produces a circulation of the oil upwards in the annular space and downwards in the shell. The apparatus is arranged so that any temperatures and pressures may be used.—T. A. S.

Gasoline; Apparatus for recovery of —— from casing-head gas. W. R. McGinnis, Assr. to Pilsbry-Becker Engineering and Supply Co. U.S.P. 1,418,876, 6.6.22. Appl., 23.8.19.

Two scrubbers are used, each provided with baffles, refrigeration apparatus, and a sprinkling head. Means are provided for passing the gas down one scrubber and up the other, and also for reversing the direction of the gas.—T. A. S.

Oil separator. J. C. Pool. U.S.P. 1,418,970, 6.6.22. Appl., 18.2.20.

An apparatus for distilling oil from rock consists of a long vertical tube divided into preheating, distilling, and cooling sections. Arrangements are provided for drawing off the volatile oils from the distilling sections, for conveying heat from the distilling and cooling sections to the preheating section, and for the discharge of the residue from the bottom of the tubes.—T. A. S.

Emulsions; Process for resolving ——. H. A. Gill. From The Sharples Specialty Co. E.P. 180,447, 1.6.22.

Emulsions are resolved by adding to them colloidal solutions soluble in the continuous phase and which tend to reverse the emulsion. Soap may be added to a water-in-oil emulsion by preparing a reagent soluble in oil and yet containing soap. Such a reagent containing 25% of sodium soap, 10% of water, and 65% of oleic acid may be prepared by adding excess of oleic acid to a solution of caustic soda of 30° B. The addition of 1% of a reagent containing 40% of water, 35% of resin, and 25% of resin soap, with stirring, to a viscous oil emulsion, followed by centrifuging, resulted in a separation of water from the emulsion.—T. A. S.

Hydrocarbons; Process of separating and topping —— from a water mixture. W. A. Brown. U.S.P. 1,419,610, 13.6.22. Appl., 24.2.19.

The mixture is heated under a pressure sufficient to prevent the vaporisation of the water, thereby inducing the separation of the water from the oil. The hydrocarbons are then heated without heating the water, pressure being still maintained, and oil vapours are withdrawn.—T. A. S.

Low-boiling hydrocarbons; Process for the continuous production of —— from petroleum oils. R. W. Hanna, Assr. to Standard Oil Co. of California. U.S.P. 1,419,378, 13.6.22. Appl., 19.1.20.

The oil is distilled under reduced pressure so as to prevent cracking, the heavy oils being preferably withdrawn continuously. The high-boiling distillates to be cracked are carried forward to an apparatus kept at a pressure higher than atmospheric and a temperature sufficient for cracking. The addition of a solvent oil to the oil to be cracked prevents the formation of deposits in the system. The cracked products and residues are continuously removed.—T. A. S.

Acetylene [storage] tank. F. J. Metzger, Assr. to Air Reduction Co., Inc. U.S.P. 1,419,746, 13.6.22. Appl., 19.11.20.

See E.P. 180,273 of 1922; J., 1922, 536 A.

Explosive gases [acetylene] dissolved in liquids; Porous charge for containers serving for storage of ——. E. Klebert, Assr. to J. Pintsch A.-G. U.S.P. 1,419,862, 13.6.22. Appl., 3.1.20.

See E.P. 135,511 of 1919; J., 1920, 684 A.

Bituminous shales; Treating ——. J. H. Ginet. E.P. 181,126, 9.3.21.

See U.S.P. 1,371,160 of 1921; J., 1921, 291 A.

Drying peat. E.P. 181,035. *See* I.

Feeding fine materials to gas producers. E.P. 180,396. *See* X.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Retort; The "fusion" patent rotary ——. C. J. Goodwin. South Wales Inst. Eng., 20.4.22. [Reprint.] 12 pages.

The retort is designed for the recovery of oils from coal, shale, etc. It consists of an inner tube 18 in.

in diam., in which is situated eccentrically a four- or six-winged breaker or scraper, which is partially carried round by the rotation of the tube and then falls back, striking a glancing blow, and so keeping the heated surfaces free from scale, breaking up the material and preventing caking, deposition of carbon, and "cracking." This tube is surrounded by an outer rotating tube, about 2 ft. 6 in. in diam., which is directly heated by the combustion of gases in a chamber. The material under treatment is fed into the inner tube, and passing the length of that tube returns through the outer tube, from which it is discharged. The vapours evolved pass the length of the outer tube, return through the inner tube, and are thence discharged. A rubbing joint made of flexible steel and asbestos prevents the escape of vapours at the junction of the two tubes. The coke produced is in a finely divided state, and would require briquetting for most industrial purposes. 73·6 galls. of oil was obtained from Esthonian shale, 51·8 galls. from Nova Scotia torbanite, 131·7 galls. from Australian torbanite, and 52·5 galls. from Kimmeridge shale per ton of material. The carbon content of the residue varied from 9·50% to 26%. There was practically no "cracking" of the distillation products.—H. M.

Patents.

Thermionically-active substance [*filament*]. W. Wilson, Assr. to Western Electric Co., Incorp. U.S.P. 1,419,530, 13.6.22. Appl., 12.8.18.

A thermionically-active filament consists of a core of a ductile metal of the iron group coated with strontium and barium oxides. The activity is comparable with that of a platinum filament similarly treated.—J. S. G. T.

Peat and the like; Process for the distillation and coking of raw ——. A. J. H Haddan. From Torfverwertungsges. Pohl und Von Dewitz. E.P. 158,513, 24.1.21.

See G.P. 337,097 of 1920; J., 1921, 618 A.

Electric lamp bulbs or the like; Evacuation of ——. Patent-Treuhand-Ges. für Elektrische Glühlampen. E.P. 165,406, 22.6.21. Conv., 22.6.20.

See U.S.P. 1,410,665 of 1922; J., 1922, 363 A.

III.—TAR AND TAR PRODUCTS.

Hydrocarbons and fats; Solubility of —— *in liquid sulphur dioxide.* E. Zerner, H. Weiss, and H. Opalski. Z. angew. Chem., 1922, 35, 253—256.

Weighed quantities of the oils under investigation and liquid sulphur dioxide were heated in sealed hard glass tubes, placed in a bath, and the temperature at which turbidity was produced was observed. The commercial sulphur dioxide used contained 98·85% of sulphur dioxide, 0·56% of water, and 0·67% of oily residue. Toluol, *n*-tetradecane, *n*-pentatriacontane, decahydronaphthalene, tetrahydronaphthalene, and American kerosene were tested, also castor, rape, olive, and linseed oils and bone fat. The graphs in all cases show a maximum. Paraffins are the least soluble, naphthenes more so, and aromatic and unsaturated compounds are easily soluble. The solubility decreases with increase in molecular weight. Sulphur dioxide shows great solubility in hydrocarbons.—H. M.

Catalytic hydrogenations under pressure in the presence of nickel salts. I. Indene and acenaphthene. J. von Braun and G. Kirschbaum. Ber., 1922, 55, 1680—1686.

The method is essentially that due to Schroeter 1922, 133 A), hydrogenation being effected under a pressure of 10—15 atm. at a suitable temperature in an autoclave provided with stirring gear and in the presence of a nickel catalyst. At 200° C. indene is very readily transformed into hydrindene, b.p. 176° C., the yields being theoretical. At 210° C. technical acenaphthene, purified by a single crystallisation from alcohol, is rapidly and quantitatively reduced to tetrahydroacenaphthene (tetraphthene), b.p. 115° C. (12 mm.). The latter is distinguished from hydrindene and tetrahydronaphthalene by its ready susceptibility to oxidising agents. It is stable when preserved in closed vessels and becomes coloured merely pale yellow when exposed to air, but behaves towards permanganate as an unsaturated compound. (*Cf.* J.C.S., August.)
—H. W.

Isoquinoline and the Isoquinoline Reds. J. E. G. Harris and W. J. Pope. Chem. Soc. Trans., 1922, 121, 1029—1033.

Isoquinoline was extracted from the fraction of commercial coal-tar quinoline boiling at 230°—255° C. by taking advantage of its more powerful basic properties. 387 g. of the mixed bases was shaken with 600 c.c. of 4 *N* sulphuric acid, which left about 20% undissolved. The sulphuric acid solution was then treated with successive quantities of 4 *N* ammonia in sufficient amount to liberate about 20% of its content in base, which was removed by extraction with benzene. After eleven treatments about 6·9% of the original base remained in sulphuric acid solution, containing 20—30% of isoquinoline. This was then liberated with ammonia and purified by recrystallisation of the acid sulphate from alcohol. Pure isoquinoline hydrogen sulphate melts at 206·5°, and the pure base liberated therefrom boils at 242·5° C., somewhat higher than previously recorded in the literature. Isoquinoline Red was obtained in 70% yield and free from inorganic matter by heating isoquinoline, quinaldine, and benzotrichloride with aluminium chloride as condensing agent. It was purified by recrystallisation from boiling water. By substituting *p*-toluquinaldine or 6-ethylquinaldine for quinaldine in the above preparation 6′Methylisoquinoline Red, or 6′-Ethylisoquinoline Red was obtained.—G. F. M.

Patents.

Anthracene; Process of producing high-percentage pure ——. L. Weil. U.S.P. 1,419,186, 13.6.22. Appl., 21.12.21.

Crude anthracene is distilled with petroleum hydrocarbons of b.p. about 300° C., and the anthracene which crystallises from the distillate is separated from the residual oil.—L. A. C.

m-Hydroxybenzaldehyde; Production of ——. J. B. Slimm, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,419,695, 13.6.22. Appl., 6.1.21.

A solution of a *m*-aminobenzaldehyde-bisulphite addition product is diazotised, and the solution of the diazonium compound is heated to remove nitrogen and sulphur dioxide simultaneously.
—L. A. C.

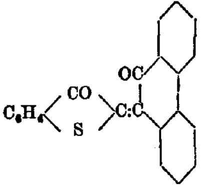
Phenylglycine bodies; Method of making ——. L. E. H. Cone, Assr. to Dow Chemical Co. U.S.P. 1,419,720, 13.6.22. Appl., 22.3.18.

A salt of chloroacetic acid is dissolved in a cold aqueous solution of aniline, and the solution added to a hot aqueous solution of aniline to form the aniline salt of phenylglycine. The freshly precipitated phenylglycine is washed with a cold aqueous solution of aniline.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

Indigoid dyes of the phenanthrene and indene series. P. Friedländer, W. Herzog, and G. von Voss. Ber., 1922, 55, 1591—1596.

2-Thionaphthene-9′-phenanthreneindigo (annexed formula), dark violet, almost black crystals,



is readily prepared by the addition of a few drops of concentrated hydrochloric acid to a boiling solution of 3-hydroxythionaphthene and phenanthraquinone in acetic acid; it gives dull violet shades on the textile fibres from a yellow vat. It is remarkable for its resistance towards solutions of alkali hydroxides, being far more stable in this respect than thionaphtheneacenaphtheneindigo (Thioindigo Scarlet 2 G). β-Ketohydrindene condenses with one proportion of isatin chloride giving 2-indole-1′-indaneindigo, which is also produced from β-ketohydrindene and α-isatinanilide in the presence of acetic anhydride. The dyestuff is decomposed with great difficulty by solutions of alkali hydroxides; it gives very intense, dark bordeaux shades on wool from a pale yellow hydrosulphite vat. The similar dyestuff from β-ketohydrindene and dibromoisatin chloride is described. Thionaphthenequinone-2-anil and β-ketohydrindene give 2-thionaphthene-1′-indaneindigo,

$$C_6H_4<{}^{CO}_{S}>C:C<{}^{CO}_{C_6H_4}>CH_2$$

reddish violet needles, which dyes textile fibres from a yellow vat in redder shades than the corresponding indole dyestuff. Similarly, thionaphthenequinone-2-anil and αγ-indanedione yield 2-thionaphthene-2′-indoneindigo,

$$C_6H_4<{}^{CO}_{S}>C:C<{}^{CO}_{CO}>C_6H_4$$

slender, reddish-violet needles. (*Cf.* J.C.S., August.)—H. W.

NN′-Diphenylindigotin. P. Friedländer and K. Kunz. Ber., 1922, 55, 1597—1607.

N-Phenylanthranilic acid is converted by hot formaldehyde solution (30%) into the so-called formalide,

$$C_6H_4<{}^{CO-\!\!-O}_{N(C_6H_5).CH_2}$$

m.p. 89° C., which is transformed by cold concentrated potassium cyanide solution into the nitrile, $CO_2H.C_6H_4.N(C_6H_5).CH_2CN$, m.p. 133°—134° C. The latter is hydrolysed to N-diphenylglycine-*o*-carboxylic acid, $CO_2H.C_6H_4.N(C_6H_5).CH_2.CO_2H$, m.p. 160°—163° C. (decomp.), which is transformed by sodium acetate and acetic anhydride or by sodium hydroxide at 190°—200° C. into phenylindoxyl. This could not be caused to crystallise. It is oxidised by potassium ferricyanide in faintly alkaline solution to diphenylindigotin, almost black, lustrous plates, in which the presence of the phenyl groups attached to the nitrogen atoms so lessens the stability of the molecule that the substance has no value as a vat dyestuff. The shade is displaced markedly towards green but not to so great an extent as with the methyl derivative. The corresponding di-4-chlorophenylindigotin is scarcely distinguishable in shade and properties from the chlorine-free dyestuff. (*Cf.* J.C.S., August.)
—H. W.

Isohæmatein; Synthesis of ——. Synthesis of isobrazilein and certain related anhydropyranol salts. II. H. G. Crabtree and R. Robinson. Chem. Soc. Trans., 1922, 121, 1033—1041.

Isohæmatein was synthesised from veratrylidenegallacetophenone dimethyl ether by hydrogenation of this to its dihydro derivative, and boiling the latter with formic acid and anhydrous zinc chloride, whereby an isohæmatein tetramethyl ether salt was obtained, and isolated as its ferrichloride which was found to be identical with the ferrichloride obtained from hæmatein through pentamethyldihydrohæmateinol. The salt forms hæmatite-red needles with a green reflex, m.p. 191° C. (with decomp.). On demethylation by warming with concentrated sulphuric acid, and converting the sulphate into hydrochloride, isohæmatein hydrochloride was obtained as orange needles. The brownish-red shades given by the synthetic substance and that obtained from hæmatoxylin on aluminium-mordanted cloth were identical and behaved in the same way on soaping and on treatment with sodium hypochlorite solution.—G. F. M.

Dyestuffs from Purpura aperta and P. lapillus. P. Friedländer. Ber., 1922, 55, 1655—1658.

The dyestuff obtained from *Purpura aperta* appears to be identical with 6.6′-dibromoindigotin as far as elementary analysis, solubility, tinctorial properties, and absorption spectrum allow a judgment to be formed. The dyestuff from *P. lapillus* is probably also a dibromoindigotin.—H. W.

Anthocyanidins; Distribution of —— in the coloured organs of plants. St. Jonesco. Comptes rend., 1922, 174, 1635—1637.

The anthocyanidins, either as a coloured pigment or in the free state, do not exist in all coloured tissues which contain anthocyan. They appear to be characteristic of pure red organs, but are replaced by a very intense yellow pigment in the blue, violet, or reddish-purple organs, in which the anthocyanidins are entirely absent. This yellow pigment is not coloured by warming with 20% hydrochloric acid. Its presence has been detected in the violet-red leaves of beetroot, the violet flowers of *Gladiolus* and *Cobœa scandens*, the reddish-purple flowers of *Canna* and of a cultivated rose, and the blue flowers of *Centaurea cyanus*.—W. G.

Isoquinoline Reds. Harris and Pope. *See* III.

Reduction of flavanone. Freudenberg and Orthner. *See* XV.

Patents.

Colouring matter of the anthracene series; Production of a ——. A. H. Davies, R. F. Thomson, J. Thomas, and Scottish Dyes, Ltd. E.P. 181,304, 27.11.20.

A vat dyestuff which dyes cotton brilliant greenish-blue shades of excellent fastness to chlorine, acids, and alkalis, is obtained by treatment of the oxidation product of dibenzanthrone with dimethyl sulphate. *Example:* 10 pts. of anhydrous sodium carbonate and 10 pts. of dimethyl sulphate are added to 10 pts. of the dried oxidation product of dibenzanthrone suspended in 100 pts. of nitrobenzene, and the mixture is boiled for 3 hrs., afterwards cooled, then 10 pts. of sodium carbonate dissolved in 200 pts. of water is added and the nitrobenzene removed by steam distillation. The product is then filtered, whereby a bluish-green paste of the dyestuff is obtained. The dyestuff crystallised from nitrobenzene has the composition $C_{34}H_{14}O_2(OCH_3)_2$ and dissolves in sulphuric acid with a reddish-violet

colour. It forms a brown amorphous compound when treated with sulphuric acid of about 80%.
—A. J. H.

o-Hydroxyazo dyes. [*Vat*] *dyes.* (A) R. Haugwitz, (B) W. Herzberg and G. Hoppe, Assrs. to Akt.-Ges. für Anilin-Fabr. U.S.P. (A) 1,419,500 and (B) 1,419,502, 13.6.22. Appl., (A) 30.8.21 and (B) 7.12.21.

(A) Sulphonic acids of the azo dyes derived from diazotised aromatic *o*-hydroxyamino compounds and a monohydroxy derivative of quinoline yield bordeaux to violet-brown shades on chrome mordanted wool. (B) The condensation products obtained by heating a 1.4-quinonoid compound halogenated in the quinonoid nucleus with an oxazine yield vats which dye fibrous material yellow to orange shades fast to chlorine and washing.
—L. A. C.

Ortho[*hydr*]*oxyazo dyes.* W. Herzberg and O. Scharfenberg, Assrs. to A.-G. für Anilinfabr. U.S.P. 1,419,501, 13.6.22. Appl., 30.8.21.

See E.P. 168,681 of 1920; J., 1921, 731 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Oxycellulose. E. Heuser and F. Stöckigt. Cellulose-Chem., 1922, 3, 61—74.

The aldehyde character of oxycellulose has been well established for a long time. Of the other characteristics the property of yielding furfural has also been previously recorded. The yield of furfural, however, is not large and only becomes substantial in oxycellulose residues which have suffered large losses in the course of their preparation. Raw cotton had a furfural value of 0·9%, and this was reduced to 0·5%, and even down to 0·3%, by digestion under pressure with water or dilute sodium hydroxide. Oxycellulose preparations generally gave furfural values below 1%; a preparation made with bromine and calcium carbonate showed over 2% and the maximum values, ranging from 2·12% to 3·89% in a very extremely oxidised residue were afforded by oxycelluloses prepared by means of chromic acid. No formation of methylfurfural groups was detected as the result of oxidation. A further characteristic of oxycellulose, definitely established by the authors, is the production of carbon dioxide on distillation with 12% hydrochloric acid; this was determined by Lefèvre's method (*cf.* Meyer, Analyse u. Konstitution org. Verb., III., 587) for the estimation of glucuronic acid. The quantities of carbon dioxide obtained rarely exceeded 1%. Here again, the maximum value of 1·32% was afforded by the highly oxidised oxycellulose prepared by means of chromic acid, while oxycellulose prepared by Knecht's permanganate method yielded 1·04%. As a qualitative test for oxycellulose, Tollens' β-naphthoresorcinol test for glucuronic acid (J., 1908, 716) may be utilised. By digestion under pressure with 1% sulphuric acid, the major portion of the substance which yields furfural and carbon dioxide is split off by hydrolysis, and a barium salt was obtained which showed many of the reactions of glucuronic acid but was not identical with barium glucuronate. This substance is regarded as the "pure" oxycellulose which occurs only in small quantities in combination with a portion of the cellulose in the oxycellulose preparations. It is an aldehyde-carboxylic acid presumably formed by the oxidation of a terminal alcoholic group of a cellobiose residue or of an aldehyde group liberated by simultaneous hydrolysis.—J. F. B.

Paper pulp; Instrument for measuring the degree of beating of ——. E. W. L. Skark. Papierfabr., 1922, 20, 845—852. (*Cf.* J., 1922, 9 A.)

An instrument called a "stuff-spindle" has been devised for testing numerically the degree of beating of paper pulp during its treatment in the hollander. It consists of a hollow metal cylinder terminating at the top in a slender open tube and carrying at the bottom a wire sieve of plain No. 50 mesh with an area of 3·14 sq. cm. (2 cm. diam.). The sieve is easily removable and must be thoroughly cleaned after each operation; it is situated in a recessed chamber of sufficient size to accommodate the cake of thickened pulp which collects on the surface of the sieve. When the instrument is immersed, sieve downwards, in a glass cylinder containing diluted pulp, water enters the cylinder through the sieve at a rate depending on the degree of beating of the pulp and the time is noted during which the instrument sinks to a mark on the tubular stem owing to the percolation of water into the body. In another form of instrument the stem is graduated and the rate of sinking is measured in terms of c.c. of water passing into the float-body in one minute. The pulp is taken from the hollander in a tin measuring vessel, the dry contents of which are determined, and is diluted with sufficient water to give a concentration of 5 g. of fibre substance per 4 litres. If the pulp is loaded an allowance is made for the mineral matter so as to preserve the fibre-concentration constant. The instrument is immersed in the diluted pulp, previously adjusted to 15° C.; the influence of temperature is very important. The instrument is calibrated by substituting for the sieve a thin metal plate, immersing the cylinder in water and running in water from a burette through the tubular stem until the spindle floats at the mark; a volume of 60 c.c. of water is a useful standard for research purposes. For practical purposes the sinking equivalent to 60 c.c. may take too long. The graduated spindle is used in such cases and the distance from the zero point is noted after one minute. The "stuff degree" is defined as the number of c.c. of water passing through the sieve of 3·14 sq. cm. area in one minute at standard fibre-concentration and temperature.—J. F. B.

Sulphite process [*for the production of wood pulp*]; *Chemistry of the* ——. R. N. Miller and W. H. Swanson. Paper, Apr. 19, 1922, 96—104.

The changes that take place during the cooking of sulphite pulp and their relation to the character of the pulp produced have been investigated in a series of experimental cooks conducted under the same conditions of acid strength, temperature, and pressure, and blown at 9, 10, 11, 11½, 12, 12½, and 13½ hrs. respectively. An examination of the pulp and acid liquor at these intervals indicates that, to obtain the best pulp under given conditions of temperature, pressure, and acid strength, the digester should be blown when a sample of the acid liquor shows a maximum value for loosely combined SO_2 (*cf.* J., 1919, 38 A) and a low value for combined SO_2. The Sander reaction (J., 1915, 225; 1921, 256 A) is employed in the analysis of the acid liquor; 2 c.c. of the sample is diluted and titrated with $N/8$ sodium hydroxide using methyl orange as indicator, excess of saturated mercuric chloride solution is added and the solution again titrated to neutrality with $N/8$ alkali. The second titration is a measure of the total SO_2; the difference between the second and first is a measure of the combined SO_2, as shown in the following equations:—

(i) $H_2SO_3+NaOH=NaHSO_3+H_2O$, (ii) $Ca(HSO_3)_2+NaHSO_3+3HgCl_2=Ca(HgClSO_3)_2+NaHgClSO_3+3HCl$. The difference between the figure for total SO_2 determined as above and that obtained by titration with iodine gives an approximate value for loosely combined SO_2, sufficiently accurate, however, for the control of the cook. Determinations of the lignin content of the pulps show that the removal of lignin commences at temperatures little above 100° C. and proceeds with vigour through all intermediate temperatures up to the maximum attained.
—D. J. N.

Sulphite acid; Analysis of reclaimed ——. G. P. Genberg. Paper, Apr. 19, 1922, 122—123.

THE following scheme is suggested for the analysis of reclaimed sulphite acid:—*Total SO_2*: 20 c.c of the acid, withdrawn under pressure, is diluted to 500 c.c. and run from a burette into a known volume of $N/16$ iodine solution until in slight excess, more iodine solution is added to restore the yellow colour, and the end-point finally adjusted after addition of starch. *Sulphur trioxide*: 50 c.c. of acid is evaporated to dryness with an equal volume of hydrochloric acid and the residue boiled with 5 c.c. of hydrochloric acid and 100 c.c. of water, filtered hot, and precipitated with barium chloride. *Calcium sulphite*: to 50 c.c. of sulphite acid, 15 c.c. of 26% ammonia is added, drop by drop, with constant stirring, and, after standing for 10 mins., the precipitated calcium sulphite is filtered off and washed with three 25 c.c. lots of 14% ammonia; the precipitate is then washed into a 500 c.c. flask and, after addition of 5 c.c. of hydrochloric acid, is made up to the mark and titrated against $N/16$ iodine solution as described above. Total lime may be estimated as oxalate on 20 c.c. of the acid liquor after diluting and boiling with hydrochloric acid until free from sulphur dioxide. The lime thus obtained should agree within 2% with that required for the SO_2 and combined SO_2 determined above.
—D. J. N.

Sulphite pulp; Use of rotten and stained wood in the manufacture of ——. E. Sutermeister. Pulp and Paper Mag., 1922, **20**, 513—514.

COMPARATIVE boils using sound wood, wood thoroughly permeated with the threads of dry rot, but still quite hard and firm, and wood stained a greyish-brown colour (often found in spruce logs which have been stored in a very wet condition with the bark on), indicate that, if a high grade of pulp is required, wood affected by dry rot, or stained wood, should not be used, even in admixture with sound wood. The pulp from the rotten wood was found to be weak, poor in colour, and practically impossible to bleach; that from the stained wood was also poor in colour and required 15·5% of bleach as against 8·6% for best selected wood; in both cases the unbleached pulp was full of dark brown shives. Figures for yield show that, whereas rotten wood gives a lower yield of air-dry pulp per cord than does sound wood, staining does not materially affect the yield.—D. J. N.

Copper oxide-ammine-cellulose solutions. Traube. *See* VII.

PATENTS.

Textile fibres; Degumming or preparatory treatment of ——. M. Sabner. E.P. 178,570, 20.1.21.

A CONTINUOUS process is described for degumming textile fibres such as jute, ramie, flax, and the like. The apparatus consists of a series of hollow, disc-like chests arranged around, and in internal communication with, a central supply pipe. These chests are perforated on the underside so that liquid supplied through the central pipe is sprayed on to the fibres, which are laid in an open and straight condition in trays between the chests; the trays are provided with perforated bottoms and imperforate sides, so that the treating liquid continuously passes through the fibres. The whole apparatus is slipped into a digester, and the supply pipe connected by a flexible joint to an inlet pipe passing through the side of the digester; the fibres are then treated with the necessary degumming chemicals, supplied under pressure, steamed and washed without further handling. Liquid is drawn off at the bottom of the digester as required.—D. J. N.

Fibres; Method of protecting animal —— *from the injurious effect of alkaline liquids.* P. Goldberg, P. Onnertz, and A. Peters, Assrs. to Akt.-Ges. f. Anilin Fabr. U.S.P. 1,419,497, 13.6.22. Appl., 15.8.21.

THE addition of sulphite-cellulose waste liquors to alkaline liquids inhibits the injurious effect of the liquids on animal fibres.—L. A. C.

Paper; Method of manufacturing —— *[at high speeds].* W. P. Carpmael. From The Bagley and Sewall Co. E.P. 181,140, 16.3.21.

A STRONG and satisfactory web of paper may be made at high speeds, *e.g.* 1000 ft. per min., on a Fourdrinier or similar type machine, by feeding the water and stock on to the machine under pressure, and providing means whereby the stock, after passing under the slice, accumulates in a pool, through which the rate of flow of the stuff is approximately equal to the speed of the wire. The desired velocity is imparted to the stock by using more water than is usual, and suitably adjusting the pressure head in the flow box. The pool may be formed by extending the apron over the machine wire for a short distance or by placing the slice behind the axis of the breast roll. Difficulty may be experienced when running at high speeds in removing the water from the web; in such cases the suction box end of the wire should be raised to give the water more opportunity of draining away. The main feature of this process is that by maintaining a pool of stock above the wire the fibres become well mixed and give a well felted sheet.—D. J. N.

Cellulose; Treatment of crude ——. C. Harnist. E.P. 156,777, 7.1.21. Conv., 6.7.14.

SEE F.P. 477,895 of 1914; J., 1917, 132. By using potash, or the potassium salt of a weak acid, such as carbonic or sulphurous acid, in the alkaline digestion treatment, residual lyes containing potash, suitable for use as a fertiliser, are obtained.

Viscose silk; Manufacture of ——. E. Bronnert. U.S.P. 1,419,714, 13.6.22. Appl., 30.8.20.

SEE E.P. 170,024 of 1920; J., 1921, 843 A.

Carroting hairs; Process for ——. C. Pichard, Assr. to Pichard Frères. U.S.P. 1,419,754, 13.6.22. Appl., 3.5.21.

SEE E.P. 163,297 of 1921; J., 1922, 541 A.

Spinning artificial threads; Rotary pumps [of the gear type] for use in apparatus for ——. British Cellulose and Chemical Mfg. Co., Ltd., and H. R. A. Mallock. E.P. 181,085, 2.3.21.

Paper stock; Hollanders or similar machinery for cleaning ——. H. W. Southworth. E.P. 181,220, 13.5.21.

Mixtures of starch and sulphuric acid. E.P. 181,197–8. *See* XVII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Patents.

Mercerisation of yarns in hank form [; Machine for ——]. F. J. Copley. E.P. 180,739, 25.2.21.

Hanks of yarn are extended between bobbins permanently attached to a chain which passes continuously through tanks containing the mercerising and washing liquors. Arrangements are provided whereby the bobbins are rotated and the hanks are subjected to tension.—A. J. H.

Furs, feathers, hairs, skins, and the like material; Process for dyeing ——. A. G. Bloxam. From Akt.-Ges. f. Anilin-Fabr. E.P. 180,905, 7.6.21.

Furs and the like are dyed brown shades by treatment with a neutral or feebly alkaline solution of 1.4-diamino-2-chlorobenzene in the presence of oxidising agents. Skins, either unmordanted or prepared with chromium or iron mordants, on treatment at ordinary temperatures in a bath containing, *e.g.*, 2 g. of 1.4-diamino-2-chlorobenzene, 1 g. of ammonia, and 30 g. of hydrogen peroxide per l., are dyed reddish-brown shades; while skins prepared with a copper mordant are dyed an olive tint on similar treatment.—L. A. C.

Bleaching, dyeing, finishing and otherwise treating fabrics; Machines for ——. J. Thornber and A. B. Henshilwood. E.P. 181,552, 19.4.21. Addn. to 122,241.

The patent relates to a removable framework having guiding surfaces for the coiled fabrics, for use in connexion with machines of the type claimed in the chief patent (J., 1919, 132 A).

Dyeing hanks of yarn and the like; [Bearings for agitator spindles of] machines for ——. G. Lee and Sons, Ltd., and G. Pinder. E.P. 181,506, 19.3.21.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Modern methods of concentrating ——. P. S. Gilchrist. Chem. and Met. Eng., 1922, **26**, 1159—1162.

A plant consisting of a combination of an over-heat pan and packed tower, of which two 50-ton units have been in operation since 1916, is described. The weak acid is fed into a tower packed with checkered brickwork or quartz and flows thence into a long horizontal bath, about 9 in. deep, contained in the fire flue from an oil burner. A scrubbing tower packed with rings or quartz, and an electrical precipitator are also used. Owing to the effect of surface evaporation the acid leaves the apparatus at 50° F. (28° C.) below its boiling point, which in the case of sludge acid containing carbonaceous matter reduces the loss of acid by reduction, while the moderate tower temperature increases the life of the packing. The fuel consumption is 11 galls. of oil per ton of acid of 66° B. (sp. gr. 1·84) concentrated from 54° B. (sp. gr. 1·598). The outer walls of the towers are built of acid-proof shale brick and silicate cement, lined on the inside with several layers of 1-in. tiles. A variation of this apparatus specially intended for concentrating sludge acid has as its feature the blowing of flue gases at 1200° F. (650° C.) through the acid instead of simple concentration by top heat. The preheated acid is contained in a lead pan lined with acid-proof brick and the gases are blown in through acid-resisting iron pipes. The foaming which occurs through the decomposition of hydrocarbons when the density reaches about 55° B. is avoided by effecting the concentration in two stages in duplicate units. A series of cost estimates for different methods is given.—C. I.

Hydrocyanic acid; Formation of —— from nitrogen and hydrocarbons in the electric arc. A. Koenig and W. Hubbuch. Z. Elektrochem., 1922, **28**, 202—223.

When nitrogen mixed with acetylene, ethylene, or methane is passed through an arc rotating in an electro-magnetic field, hydrocyanic acid is produced. With a relatively slow rate of flow methane gives the largest yield of hydrocyanic acid, 40%, irrespective of its concentration within the limits 2—11%. With methane there is no deposition of carbon. Ethylene and acetylene mixed with hydrogen and nitrogen show definite maxima in the yields at the point where the deposition of carbon commences. Mixtures of acetylene and nitrogen give a maximum yield in the region where there is a heavy deposition of carbon. With more rapid rates of flow the best yields are obtained with acetylene. Very good utilisation of energy and yield of material are obtained when a mixture of 30% of hydrogen and 70% of nitrogen is mixed with 7—8% of acetylene and passed at the rate of 20 litres per hour through the arc, and there is no deposition of carbon. With a rate of flow up to 100 litres per hour the yield from mixtures of nitrogen, hydrogen, and acetylene containing a large excess of nitrogen reaches a maximum of 10—11 g. HCN per kw.-hr. (*Cf.* J.C.S., July.)—J. F. S.

Phosphoric acid; Manufacture of —— in the electric furnace by the condensation and electric precipitation method. T. Swann. J. Ind. Eng. Chem., 1922, **14**, 630—631.

Phosphatic rock, coke, sand, and iron borings are smelted in an electric furnace. A certain portion of the phosphorus which is liberated is absorbed by the iron and is tapped from the furnace as ferro-phosphorus containing 24—25% P. The lime and sand also leave the furnace in combination as a slag, and the remainder of the phosphorus passes through the charge with the furnace gases, which are oxidised by air and drawn out of the furnace into a condensing and precipitating apparatus. The acid as collected is light brown in colour and contains 90—95% H_3PO_4; it is treated for the removal of certain impurities. An exceptionally pure acid may be obtained by crystallisation. A high-grade concentrated acid and ferro-phosphorus are thus produced directly by the electric furnace process at a cost comparable with that of present methods.—G. F. M.

Nitric acid; Economic production of oxidation reactions in factories where —— is synthesised. Applications. C. Matignon. Bull. Soc. Chim., 1922, **31**, 555—561.

It is proposed to use the dilute nitric acid, such as is obtained in the fixation of atmospheric nitrogen or in the oxidation of ammonia, for processes in which the acid can be used as an oxidising agent, providing the consequent reduction of the nitric acid does not proceed beyond the stage of nitric oxide. The oxides of nitrogen can be reconverted into nitric acid by atmospheric oxygen and again absorbed in the towers. In this way there is practically no loss of nitric acid, and thus the expense of the oxidation process is very small. Suggested applications are the preparation of copper sulphate from copper by the combined action of sulphuric and nitric acids, and the oxidation of sugar or molasses to oxalic acid by the action of nitric acid. This latter process was satisfactorily carried through with a cargo of sugar damaged by sea water.—W. G.

Ammonia oxidation; Some economic aspects of ——. G. B. Taylor. Chem. and Met. Eng., 1922, **26**, 1217—1219.

The economic possibility of the oxidation of ammonia for the large-scale manufacture of concentrated nitric acid is discussed, and it is shown that if the costs of nitrogen in the forms of ammonia and of sodium nitrate are on a parity the use of the former is uneconomical, as the high cost of concentrating the relatively weak nitric acid produced offsets other savings. In this calculation the overall efficiency of ammonia oxidation is taken as 90%. In the case of processes requiring weak nitric acid, or merely oxides of nitrogen as in the lead chamber sulphuric acid process, the ammonia process has the advantage.—C. I.

Soda and hydrogen sulphide; Manufacture of —— *from sodium sulphate and coal.* J. Michler. Chem.-Zeit., 1922, **46**, 633—634.

Finely ground sodium sulphate is mixed with finely ground coal and the mixture briquetted. The briquettes are charged into a gas-tight furnace and heated with a mixture of producer-gas with a slight deficiency of air. The charge is kept at a bright red heat until a test shows that less than 1% of sodium sulphate remains undecomposed. The charge is allowed to cool to a dull red and a mixture of steam and carbon dioxide is passed in, whereby the sodium sulphide formed in the first stage is decomposed into carbonate with the evolution of hydrogen sulphide. The issuing gases contain about 30—40 vols. % of hydrogen sulphide and may be utilised for the production of sulphur by the Chance process. The residue contains less than 0·1% of sodium sulphide, and after leaching the solution contains 96% Na_2CO_3 calculated on the total solids. The process is preferably carried out in a series of furnaces, the spent gases from the first stage (which contain some hydrogen sulphide) being used in the second stage, so that by suitable working an economical recovery of sulphur is obtained in gases containing at least 30% of hydrogen sulphide, *e.g.*, by passing the carbon dioxide mixture through the series in such a manner that it first comes in contact with material poor in sulphur. The briquettes emerge from the process in the same shape as they went in and are conveniently porous for leaching.—A. R. P.

Chlorine and hypochlorous acid; Determination of —— *in concentrated salt solutions.* M. C. Taylor and C. A. Gammal. J. Ind. Eng. Chem., 1922, **14**, 632—635.

The determination of free chlorine and hypochlorous acid in concentrated salt solutions which may contain either sodium hypochlorite or hypochlorous acid, is usually carried out by a determination of total "available" chlorine, and then of free chlorine by an aeration process. The latter, however, is inaccurate owing to decomposition of hypochlorous acid or of hypochlorite during aeration. It is now shown that the rate of the removal of the free chlorine is a linear function of the amount present at any moment, whilst when all free chlorine has been removed the rate of removal varies directly as the square of the hypochlorous acid present. The curves obtained, therefore, by plotting the rate of the removal of chlorine against the total amount removed as measured by absorption in potassium iodide and titration with thiosulphate will be two lines having a point of intersection from which a vertical line to the horizontal axis shows the initial amount of free chlorine present. As the actual loss of available chlorine during aeration, due for example to the decomposition $HOCl \rightarrow HCl + O$, is equal to the increase in acidity measured in terms of thiosulphate by means of potassium iodide-iodate solution, a calculation can also be made of the amount of chlorine initially present as hypochlorite or as hypochlorous acid and hydrochloric acid. —G. F. M.

Ammonia; Reactivity of ——. E. C. C. Baly and H. M. Duncan. Chem. Soc. Trans., 1922, **121**, 1008—1014.

The decomposition of ammonia by means of a heated platinum wire gives constant values for the same amount of energy with an active form of the gas derived either by slow evaporation from a cylinder of compressed gas, or by gently heating the concentrated aqueous solution, the gas being dried by quicklime, or by evaporating isothermally at the boiling point the gas obtained by either of these methods. A second "inactive" type, obtained by rapid evaporation of the liquefied gas, gives much smaller decomposition values under the same conditions. On standing in contact with the liquefied gas, or by heating to 200° C. with a platinum wire, this type slowly becomes active. The ratio of the decomposition values obtained by a first and second exposure of the gas to the heated wire differs markedly in the two forms. Addition of water vapour increases the reactivity of ammonia proportionally to the amount of water present, an increase which is lost on drying with quicklime. Hence two different molecular phases of ammonia exist possessing different energy content and reactivities, that of lower energy content being identical with completely dry ammonia. The active and inactive forms of ammonia described differ in the relative amounts of these two phases which they contain. In order to observe these phenomena the platinum wire must be activated as for the Ostwald process for the catalytic oxidation of ammonia in air to nitric acid.—P. V. M.

Sulphuryl chloride; Researches on ——. *II. A new chlorinating agent. Preparation of polychloro-derivatives of benzene.* O. Silberrad. Chem. Soc. Trans., 1922, **121**, 1015—1022.

A solution of sulphur monochloride in sulphuryl chloride in contact with aluminium chloride is a vigorous chlorinating agent, capable of bringing about any degree of chlorination. For purposes of chlorination 250 pts. of sulphur monochloride is run into excess of sulphuryl chloride; 68·2 pts. of this mixture contains 1 g.-equiv. of active chlorine or 0·5 g.-mol. of sulphuryl chloride. The compound to be chlorinated, 1 to 2 mols., plus 5 to 10 g. of finely-ground anhydrous aluminium chloride, is treated with 5 to 10% excess of the chlorinating mixture in a vessel provided with an efficient reflux condenser, the upper end of which is connected with a second condenser loosely packed with asbestos; the two condensers are arranged so that the gases pass up the former and down the latter, the condensate from the second being returned through a trap to the reaction vessel, while the gases evolved are conducted through a valve to a vessel containing water. The reaction mixture is cooled or warmed according to the vigour of the reaction, which is completed by warming for a short time. The product is washed with water and purified by suitable means. The preparation of the polychloro-derivatives of benzene is described. —P. V. M.

Specific heat of gases for calculations concerned with technical heating. Sulphur dioxide. B. Neumann. Z. angew. Chem., 1922, **35**, 367.

The figures previously given (J., 1919, 618 A) for the true specific heat of sulphur dioxide at temperatures between 0° and 3000° C. and the mean specific heat between 0° and *t*° C. (calculated for 1 kg. of gas) are inaccurate. The heading to the second column on the above page of this Journal should be amended by deleting "SO_2" and a new column added giving the specific heat of sulphur dioxide at constant pressure calculated for 1 kg. of gas as follows:

t° C.	0°	100°	200°	300°	400°	500°	1000°	1500°	2000°	2500°	3000°
Sp. heat	0·139	0·148	0·158	0·168	0·177	0·184	0·204	0·2125	0·219	0·225	0·231.

—A. R. P.

Ammonium nitrate; Properties of ——. *II. Ammonium nitrate and water.* I. L. Millican, A. F. Joseph, and T. M. Lowry. Chem. Soc. Trans., 1922, 121, 959—963. (*Cf.* J., 1920, 105 A.)

The depression of the freezing point of ammonium nitrate by water has been determined from 170° to 6° C., from which, together with earlier data, the complete equilibrium diagram from 0 to 100% ammonium nitrate has been plotted. There is a sharp break in the curve at 125° C., but none at 84° C., indicating identical solubilities and temperature coefficients of the α and δ forms of the salt. The extension of the curve below the normal transition point, 32° C., through which the curve passes with only a very slight break, represents the freezing points of its metastable phase.—P. V. M.

Ammonium nitrate; Properties of ——. *III. Ammonium nitrate and sodium nitrate.* R. G. Early and T. M. Lowry. Chem. Soc. Trans., 1922, 121, 963—969.

The freezing point curve of ammonium nitrate and sodium nitrate from 9 to 49% of sodium nitrate consists of three rectilinear sections corresponding with the separation of the ε and δ forms of ammonium nitrate and one form of sodium nitrate. The crystallisation curve of ammonium nitrate prolonged backwards cuts the temperature axis at 156° C., a similar value being obtained from the freezing point curve of ammonium nitrate and silver nitrate, indicating that temperature as the melting point of the metastable δ-ammonium nitrate. The eutectic point for ammonium nitrate and sodium nitrate lies at 120·8° C., corresponding to 20·5% of sodium nitrate. No evidence of isomorphism has been observed.—P. V. M.

Gypsum; Conversion of —— *into ammonium sulphate.* C. Matignon and M. Fréjacques. Comptes rend., 1922, 175, 33—35.

The authors obtained a 96% yield of ammonium sulphate in the interaction of a commercial sample of gypsum with ammonium carbonate (*cf.* Neumann, J., 1921, 692 A). The curves giving the velocity of the reaction show the existence of two distinct phases, during the first of which the velocity is lower than in the second. The presence of ammonium sulphate in the original solution causes a diminution in the velocity of the reaction, but in all cases equilibrium is reached at the end of 2¼ hours.—W. G.

Potash felspar; Melting of ——. G. W. Morey and N. L. Bowen. Amer. J. Sci., 1922, 4, 1—21.

Pure synthetic crystals of potash felspar, prepared by crystallising a glass of the composition $KAlSi_3O_8$ in a bomb with water vapour, when rapidly heated appear to melt to a clear glass at about 1200° C. If kept at this temperature for some days, however, microscopical examination reveals the presence of a crystalline framework of leucite ($KAlSi_2O_6$), which, at higher temperatures, becomes more distinct, eventually melting at about 1530° C. The first appearance of this decomposition was noticed at 1170° C. Similar results are obtained with natural potash felspars, but the temperatures at which melting begins and finishes are modified by the presence of impurities. The petrogenic significance of the results is discussed with reference to the formation of the leucite-granite porphyry of Brazil and the syenite laccolith at Loch Borolan in Scotland.—A. R. P.

Sodium perborate; Electrolytic preparation of ——. K. Arndt and E. Hantge. Z. Elektrochem., 1922, 28, 263—273.

Sodium perborate is best prepared by the electrolysis of a solution of 120 g. of anhydrous sodium carbonate and 30 g. of borax per litre at 14°—16° C., using an anodic current density of 10—20 amp. per sq. dm. The yield is increased by the addition of 0·5 g. of sodium chromate and one drop of Turkey-red oil per litre. These substances eliminate cathodic reduction of the perborate. A bright platinum anode is used, and the cathode is a length of water-cooled tin tubing. The solution must be kept free from platinum or iron compounds, for these substances reduce the yield. Increase in temperature also decreases the yield. During the electrolysis there is a loss of carbon dioxide, and if this is not replaced the current yield becomes very poor. (*Cf.* J.C.S., Aug.)—J. F. S.

Chlorites; Oxidation and reduction reactions with ——. G. R. Levi. Atti R. Accad. Lincei, 1922, 31, I., 370—373.

In most of its reactions sodium chlorite exhibits oxidising properties, but towards ozone it acts as a reducing agent. (*Cf.* J.C.S., Aug.)—T. H. P.

Permutite; Dependence of the equilibrium of bases in —— *on the concentration of the surrounding solution.* A. Günther-Schulze. Z. Elektrochem., 1922, 28, 85—89.

The equilibrium between the solid permutite and the bases in the solution for the cases of silver-ammonium, copper-ammonium, and lanthanum-ammonium at 22° C. is in all probability in keeping with the law of mass action.—J. F. S.

Copper salts; Determination of complex formation in aqueous solutions of —— *by means of permutite.* A. Günther-Schulze. Z. Elektrochem., 1922, 28, 89—99.

The formation of complexes in solutions of copper chloride, acetate, formate, sulphate, chlorate, nitrate, and bromide has been investigated by shaking known concentrations of the salts with pure potassium-permutite. The complex cation CuR is present in practically all the solutions of copper salts examined even at the greatest dilution. The complex Cu_2R_2 is present only in the chloride and bromide solutions, whilst with the other salts probably a higher complex is formed, though not in great amount. The complexity of copper salt solutions increases at constant concentration with the strength of the acid and is greater with the salts of the halogen acids than with the salts of oxygen acids of equal strengths.—J. F. S.

Alkaline copper oxide solutions and copper oxide-ammine-cellulose solutions. II. W. Traube. Ber., 1922, 55, 1899—1912. (*Cf.* J., 1922, 97 A.)

The reaction between copper ethylenediamine-hydroxide and glycerol probably takes place in accordance with the following equation, where en = ethylenediamine:—

$$2CH_2(OH)\cdot CH(OH)\cdot CH_2(OH)+2[Cu(en)_2](OH)_2 = [Cu(en)_2](O\cdot CH_2\cdot CH(OH)\cdot CH_2O\cdot)_2Cu+4H_2O+2(en).$$

The isolation of the compound,

$$[Cu(en)_2](O\cdot CH_2\cdot CH(OH)\cdot CH_2O)_2Cu,$$

in an almost homogeneous condition is described. The conclusions thus reached in the studies with glycerol can be extended to other polyhydroxy substances, notably cellulose. The ability of copper oxide-ethylenediamine-cellulose solutions to dissolve further quantities of copper oxide depends on the liberation of the ethylenediamine; the behaviour of Schweizer's solution may be explained similarly. The difference between the behaviour towards polyhydroxy compounds of the copper bases and those of the metals, silver, cobalt, nickel, zinc, and cadminum is accounted for, since only the former is able to form complexes in which the metallic atom is fixed directly to the hydroxy group of the polyhydroxy compound. An uncertainty appears to exist in the case of cobalt, according to the literature, the precipitation of this metal from its solutions as hydroxide by means of alkali is hindered by the presence of glycerol in the same manner as is the precipitation of copper hydroxide from copper solutions; the exception is only apparent, however, since the cobalt hydroxide is present in the colloidal state (and not as the glycerate) and can be precipitated completely by barium sulphate.—H. W.

Copper sulphide; Structural formula for ——. W. Gluud. Ber., 1922, 55, 1760—1761. (*Cf.* J., 1922, 370 A.)

If hydrogen sulphide is passed into a 1·5% solution of copper sulphate in ammonia (10%) until only a faint blue colour remains, a variety of copper sulphide is precipitated which yields elementary sulphur on immediate oxidation with air, whereas after preservation for 4—5 hrs. it is oxidised to copper sulphate or thiosulphate. It is suggested that the formulæ, Cu:S and Cu$_2$S:S, are to be assigned to the two modifications. This conception is in harmony with the known tendency of copper sulphide to pass into cuprous sulphide. The modification which yields free sulphur does not give potassium thiocyanate when treated with potassium cyanide; this reaction is shown strongly by the other variety. The changes may be expressed as follows: (1) $2CuS+10KCN=K_6Cu_2C_8N_8+2K_2S+C_2N_2$, and $C_2N_2+H_2O=HCN+HCNO$. (2) $Cu_2S_2+8KCN=K_6Cu_2C_8N_8+K_2S_2$ and $K_2S_2+KCN=K_2S+KCNS$. —H. W.

[Chromic] oxides; Hydrous ——. H. B. Weiser. J. Phys. Chem., 1922, 26, 401—434. (*Cf.* J., 1920, 781 A.)

From a study of various hydrous chromic oxides prepared in different ways, it is concluded that no definite hydrates of chromic oxide are formed by precipitating a chromic salt with alkali. The evidence that Guignet's green is a definite hydrate is inconclusive. The respective properties of positively and negatively charged colloidal suspensions of hydrous chromous oxides, more especially the precipitating and peptising action of alkali salts, are discussed. (*Cf.* J.C.S., Aug.)—J. S. G. T.

Lead oxides; Effect of grinding upon the apparent density of ——. O. W. Brown, S. V. Cook, and J. C. Warner. J. Phys. Chem., 1922, 26, 477—480.

The apparent density of heavy crystalline lead oxide is diminished initially by grinding, the minimum value being attained by grinding for about 10 hrs. in a pebble mill making 50 revs. per min. Thereafter the apparent density increases, rapidly at first, to a constant value greater than the initial value. The initial decrease of apparent density is not shown by a light amorphous lead oxide. By fine grinding, oxides suitable for the manufacture of storage battery plates can be produced from oxides which in their original state are worthless for this purpose.—J. S. G. T.

Banded structures. Synthesis of banded minerals. S. S. Bhatnagar and K. K. Mathur. Kolloid-Zeits., 1922, 30, 368—371.

Banded structures in agates, sandstone, pisolithic and oolithic structures are produced in the same manner as the Liesegang rings in gels. Artificial agates may be prepared as follows: 12·5 g. of sodium silicate in 100 c.c. of water is treated with a 10% solution of ammonium acetate; within 10 secs. a transparent gel is produced. Before the addition of the acetate, the silicate solution is mixed with hydrogen sulphide, sodium phosphate, potassium ferrocyanide, or potassium iodide, depending on the colour of the bands desired. After the gel is formed a solution of ferric chloride or mercuric chloride is added and left to diffuse into the gel, when the banded structure is produced. The gel is then dehydrated by pressure and gentle heating and eventually reaches a hardness of 5, and is in every way similar to natural agate. Banded sandstone is produced by adding 10 c.c. of 2·27*M* sodium silicate solution and vigorously centrifuging the mixture. A weak solution of sodium carbonate and a 10% solution of ammonium acetate are added, and after 12 hrs. the sand has become cemented by the silicic acid gel. The mass is then placed in a 10% solution of cobalt nitrate and left for some time, when bands of cobalt carbonate are produced throughout the mass.—J. F. S.

Platinum; Recovery of —— from used contact mass at the Old Hickory Powder Plant. A. L. Kibler. J. Ind. Eng. Chem., 1922, 14, 636—641.

The contact mass consisted of fused grained magnesium sulphate impregnated with platinum. It was first treated with hot water to dissolve out the soluble portions, and after allowing to settle, the insoluble sludge, consisting of platinum together with iron rust, insoluble magnesium salts, sand, gelatinous silicic acid, etc., was separated by means of a Sharples supercentrifuge. The sludge was then concentrated by digestion with weak hydrochloric acid and again centrifuged, and the concentrated sludge extracted with *aqua regia* and the extract evaporated to dryness two or three times with hydrochloric acid. The platinic chloride formed was dissolved out of the dry residue by two or three treatments with dilute hydrochloric acid, and the platinum was precipitated from the clear solution as ammonium chloroplatinate. The mother liquor was siphoned off, the precipitate washed several times with alcohol, and finally centrifuged and dried. The dry salt was then converted, by roasting in crucibles in a muffle furnace to a temperature of 1300° F. (700° C.), into platinum sponge. The platinum from the waste acid and alcohol liquors was recovered by precipitation with zinc, solution in *aqua regia*, and subsequent purification as above. In all 8812 oz. troy of platinum sponge of about 94% purity was recovered from 343,241 lb. of contact mass.—G. F. M.

Amorphous precipitates and crystalline sols. F. Haber. Ber., 1922, 55, 1717—1733.

Crystalline or amorphous solid masses are obtained by supersaturation processes which may be considered to occur in two distinct phases, the formation of aggregates and the re-arrangement of such aggregates, with loss of free energy, into ordered lattice formations. These considerations, if applied to the production of very sparingly soluble substances, show that if the rate of aggregation is high and as far as possible in excess of that of arrangement, amorphous precipitates are to be expected which gradually, particularly on warming, pass into the crystalline condition. If, however, the rate of aggregation is depressed by only slightly exceeding the solubility limit, the rate of arrangement may be sufficiently high to cause the orderly formation of crystals before visible particles have separated. This, however, involves an alteration in the rate of aggregation due to electrical phenomena at the boundary of the molecules and liquid, the net result of which is that the growth of the aggregates is greatly impeded and sols are produced. These theoretical predictions are confirmed by the behaviour of the precipitates and sols of aluminium and ferric hydroxides, which, however, are to be regarded as furnishing the ideal case from which deviations may be expected in two directions. If the rate of arrangement is greater, it will not be possible to obtain the precipitates in the amorphous condition and to retain the latter during the Röntgen exposure. The rate of arrangement may be expected to be at its maximum in binary, heteropolar compounds in which the dipolar character is most marked (illustrated by the cases of the silver halides and the sulphides of mercury, zinc and cadmium). On the other hand, with molecules in which the dipolar character is not strongly accentuated, the tendency towards the formation of amorphous sols and precipitates must be more marked; this is illustrated experimentally by the cases of the hydroxides of zirconium and thorium and of arsenic sulphide.—H. W.

Hydrogen desorbed from platinum and palladium; Some properties of ——. P. Anderson. Chem. Soc. Trans., 1922, **121**, 1153—1161.

Experiments were undertaken with a view of determining whether activated hydrogen instantaneously lost its activity on desorption or whether it had a finite period of decay. It was found that the temperature of incipient reduction of both copper oxide and sulphur was distinctly lower with highly purified hydrogen which had passed through a catalytic mass of palladium previous to coming into contact with the material, than with the same hydrogen which had not traversed the palladium. The first formation of water from the oxide was detected by means of the fall in resistance of a granule of calcium chloride placed in the unknown gap of a Wheatstone bridge, and occurred at temperatures between 103° and 115° C. with several runs with ordinary hydrogen, and at 81°—87° C. with activated hydrogen. Similarly the first formation of hydrogen sulphide occurred at 112°—118° C. in the former case and 80°—83° C. in the latter. The freshly desorbed gas was also found to be ionised to some extent, as it accelerated the rate of discharge of a gold leaf electroscope. It is improbable that the slight ionisation can be the cause of the increased activity of the element, and theories of atomic hydrogen or triatomic hydrogen are also rejected on experimental grounds. The author inclines to the view that the activation is due to an increase in the internal energy of the hydrogen molecules themselves.—G. F. M.

Potassium sulphate, aluminium sulphate, water at 25° C.; The system ——. H. T. S. Britton. Chem. Soc. Trans., 1922, **121**, 982—986.

The isothermal diagram of the system potassium sulphate, aluminium sulphate, water shows three branches, each branch representing saturated solutions in equilibrium with potassium sulphate, alum, and hydrated aluminium sulphate respectively. The range of composition of solutes of saturated solutions in equilibrium with alum diminishes considerably with rise of temperature.—P. V. M.

Phosphoric acid; Production of ——. A. Kelly. E.P. 181,255, 15.7.21.

Mineral phosphate is pulverised and roasted at such a temperature that all the organic matter contained therein is destroyed, and active decolorising carbon remains evenly distributed through the mass. On withdrawal from the furnace the product is reduced to powder and then treated in the known manner with sulphuric acid for the direct production of colourless phosphoric acid.—H. R. D.

Prussic [hydrocyanic] acid; Manufacture of ——. Deutsche Gold- u. Silber-Scheide-Anstalt vorm. Roessler, and O. Liebknecht. E.P. 181,058, 7.2.21.

A gas mixture containing carbon, nitrogen, and hydrogen, *e.g.*, a mixture of 5% of carbon monoxide, 18% of methane, 34% of hydrogen, and 43% of nitrogen, is heated in a high-tension arc at pressures above atmospheric, whereby an increased yield of hydrocyanic acid is obtained.—C. I.

Pulverous material [e.g., for fixing nitrogen]; Process for agglomerating ——. C. T. Thorssell and O. Troell. E.P. 181,413, 2.2.21.

A mixture which is required in a granular form, *e.g.*, the mixture of alkali carbonate and carbon for the synthesis of cyanide from atmospheric nitrogen, is wetted and then passed through three series of rotating cylinders. In the first it is dried by fire gases to a moisture content necessary for agglomeration, emerging as soft irregular masses; in the second the granulation is completed, the moisture being kept constant by admission of steam; in the last the granules are dried. The steam and dust from the last-mentioned apparatus are returned to the one before. The fire gases travel in the same direction as the material in order to avoid combustion of the carbon.—C. I.

Ammonia; Method for the catalytic oxidation of —— *with oxygen.* I. W. Cederberg and H. M. Bäckström. E.P. 181,486, 15.3.21.

The oxidation of ammonia gas by oxygen in mixtures containing up to 35—40% of ammonia is carried out without overheating or risk of explosion by the use of a series of catalytic masses in which the concentration of the catalyst (*e.g.*, platinum) successively increases. These masses, *e.g.*, plates of pumice, are separated from each other by nettings of nickel or other inactive material held within nickel rings, which serve to dissipate the heat of reaction.—C. I.

Bicarbonate of soda and ammonium chloride; Processes for production of ——. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des. Proc. G. Claude. E.P. 160,172, 15.3.21. Conv., 17.3.20.

The object of this invention is to avoid certain drawbacks of the processes described in E.P. 131,870 (J., 1920, 266 A). The process now described, which is characterised by the presence of ammonium carbonate in excess in the liquids throughout the series of operations, comprises the following successive steps: The mother liquor, from which sodium bicarbonate has been precipitated, and containing ammonium carbonate in excess, is cooled to 5° C. to remove ammonium chloride. Sodium chloride and gaseous ammonia are then added to the liquor in quantities corresponding to the amount of sodium bicarbonate it is desired to produce and precipitate. Sufficient carbon dioxide is passed into the solution to transform the sodium chloride and free ammonia into equivalent amounts of ammonium chloride and sodium bicarbonate. The bicarbonate is separated, thus leaving a mother liquor which is cooled to 5° C. for the removal of ammonium chloride. The cycle of operations is then repeated.—H. R. D.

Ammonia; Synthesis of ——. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des. Proc. G. Claude. E.P. 161,195, 6.4.21. Conv., 7.4.20.

When catalyst tubes for ammonia synthesis are cooled, *e.g.*, by a bath of molten lead as described in E.P. 155,302 (J., 1922, 371 A), they are liable to burst owing to the internal strains set up. It is proposed therefore to insulate the tubes, *e.g.*, by asbestos or enamel, in such a way as to maintain the walls at a uniform temperature, and this end is further secured by an electrical heating resistance in the insulation. Progressive mixing of cold gases with the hot gases from a heat exchanger takes place in the catalyst chamber, or the entering gases are allowed to circulate around the insulated catalyst tube, in such a way that the walls of the chamber are kept as cool as possible and the gases reach the tube at the minimum reaction temperature. The gases leave the catalyst tube at a temperature which may exceed 400° C. and the reaction can thus be maintained almost up to the end of the column.—C. I.

Caustic alkali; Eliminating colour from ——. T. C. Meadows and H. D. Ruhm, Assrs. to Eastern Potash Corp. U.S.P. 1,415,186, 9.5.22. Appl., 25.1.19.

Fluid concentrated caustic alkali is subjected to the bleaching action of an electric current.—T. H. Bu.

Earthy minerals that in native deposits are stained by colouring matters that render them useless for industrial purposes; Process for bleaching ——. A. J. Stubbs. E.P. 181,132, 12.3.21.

The finely divided mineral, *e.g.*, kaolin, barytes, felspar, bauxite, is placed in a vessel filled with water, together with pieces of iron, platinum, or, preferably, zinc, and the water is then saturated with sulphur dioxide. The sulphurous acid is reduced to "hyposulphurous acid," with liberation of oxygen which alters the degree of oxidation of the colouring substances and renders them soluble, leaving the mineral of a pure white colour.
—H. R. D.

Calcium hypochlorite; Process for rendering —— *stable.* Chem. Fabr. Griesheim-Elektron, and H. Reitz. E.P. 181,153, 23.3.21.

Calcium hypochlorite is mixed with purified sodium chloride, free from magnesium chloride, both substances being in a dry, finely ground state, and the proportions being such that 100 pts. of the mixture contains at least 10 pts. of active chlorine. The mixture can be moulded by slight pressure and made into permanent preparations.—H. R. D.

Carbon; Manufacture of pure retort ——. I. Szarvasy. E.P. 159,823, 28.2.21. Conv., 29.1.18.

Hydrogen. E.P. 181,062. *See* IIA.

VIII.—GLASS; CERAMICS.

Clays; Influence of small additions of electrolytes on the stability of clay suspensions, and the use of these in the purification of ——. H. Kohl. Ber. Deuts. Keram. Ges., 1922, **3**, 64—77.

To Zettlitz kaolin, freed from salts by washing, and suspended in water, was added *N*/10 sodium carbonate or *N*/10 sodium silicate, and the whole well mixed by shaking. Photographs of the suspensions, after 3 weeks, showed that, with increasing amounts of electrolyte, the amount of suspended material increased up to a definite maximum, after which further additions of electrolyte caused clarification. Very small percentages of calcium sulphate in the clay reduce the stability of the suspension. Sodium silicate is more efficient than sodium carbonate, and an excess of it is less harmful. The presence of soluble or colloidal silica is unnecessary when the clay contains a protective colloid such as humic acid. Clays containing soluble salts—particularly those of magnesium and calcium—are not suitable for purification by the addition of electrolytes unless these salts are first removed or rendered insoluble. Any clay, provided it does not contain too much soluble salts, shows an optimum degree of suspension, with a definite electrolyte at a definite concentration. Whether the separation of the particles of clay from the water in which they are suspended should be effected by means of electro-osmosis or by filtration or other means is a purely economic matter; it does not in any way affect the quality of the product. Quartz particles are usually too large to remain in suspension, but the smallest ones are capable of being suspended with the aid of an electrolyte, the optimum results being obtained with 0·208% Na_2CO_3 or 0·5%Na_2SiO_3. Hence, the finest particles of quartz are electro-negative, and behave like clay. A cataphoresis test showed that these particles pass to the anode, like clay, and cannot be separated from it by osmosis. Felspar behaves in a similar manner. Mica, when sufficiently finely divided, behaves with electrolytes like clay. A mixture of 70% of kaolin and 30% of mica, when treated with the optimum proportion of sodium carbonate, produced a suspension containing 80% of kaolin and 20% of mica, showing that most of the mica is retained in suspension with the clay. A cataphoresis test showed that finely divided mica passed wholly to the anode, precisely like clay, so that the finest particles of mica cannot be separated from clay, either by sedimentation or by electro-osmosis. Pyrite can, to a large extent, be separated from clay by elutriation or washing. Extremely minute particles of pyrite which remained in suspension in distilled water for 1½ days were flocculated by sodium carbonate and silicate, and also by sulphuric acid. A mixture of kaolin and these fine particles of pyrite settled in 2 hrs., and a suspension of kaolin, to which 0·5 g. of pure ferrous sulphate was added, in solution, flocculated and settled in 6 hrs. A cataphoresis test of a mixture of 80 g. of kaolin and 7 g. of pyrite effected no separation. It appears to be impossible to separate the most finely divided pyrite from clay. The occurrence of such finely divided pyrite is, however, improbable; it would rapidly be oxidised to sulphate. Ferric oxide, when sufficiently finely divided, is completely absorbed by the clay suspension, and, on electro-osmosis, it is deposited, along with the clay, on the anode. Only relatively coarse particles of silica, mica, and iron compounds can be separated from clay. No electrolyte is necessary for this separation, but its use is convenient, as it facilitates the suspension of the clay, and so makes the subsequent treatment easier. In the so-called purification of clay by electro-osmosis, the whole of the "purification" occurs in the preliminary settling tanks. The electrical treatment does not effect any further purification. At the same time, the smaller amount of space and water required when an osmosis machine is used (as compared with a filter-press) is noteworthy.—A. B. S.

Rational analysis [of ceramic materials] as a method of works control. R. Rieke. Ber. Deuts. Keram. Ges., 1922, **3**, 24—30.

Although the rational analysis of ceramic materials is not suitable for scientific investigations on account of its uncertainty, it is useful as a means of control of manufacturing processes. Some of the published methods of estimating the "clay substance" are critically reviewed. Clay substance is decomposed by heating it to 575° C., with evolution of water, forming free silica and alumina. The latter is readily soluble in hydrochloric acid if the calcining temperature has not exceeded 800° C. The amount of clay may be estimated from the water evolved on ignition or from the amount of soluble alumina formed. This method assumes that "clay substance" from all sources corresponds exactly to $Al_2O_3,2SiO_2,2H_2O$, which is not strictly the case, though the results of determinations of loss on ignition made on samples dried at 110° C. are sufficiently accurate for technical purposes, especially if checked by a determination of the alumina soluble in acid. The only source of error is the presence of organic matter, which is included in the loss on ignition. For repeated tests on clay from the same source, this error is practically constant; it is not affected by an estimation of the clay substance from the soluble alumina. As a rapid method, the author recommends Kallauner and Matejka's method: 2 g. of the sample is ignited for one hour at 750° C. in an electric furnace, and the product is heated in a water bath with 100—150 c.c. of sulphuric acid (1:1) for 3 hrs. So little of the silica enters into solution that it may be neglected and the alumina and traces of iron oxide are precipitated with ammonia, filtered off, ignited, and weighed. If a properly dried sample is available, an estimation can be completed in 6—7 hrs. Calculations of the clay substance based on (*a*) loss on ignition, (*b*) silica in ignited material soluble in 5% caustic soda solution, and (*c*) alumina in ignited material soluble in acid, showed that (*a*) and (*c*) agreed well, but (*b*) gave only about half the quantity, from which the author concludes that only one molecule of silica is liberated on ignition, and that, possibly, the clay substance is decomposed into Al_2O_3,SiO_2+SiO_2.—A. B. S.

irebricks; Determination of the compressive strength of —— at high temperatures. E. Sieurin, F. Carlsson, and B. Kjellgren. Ber. Deuts. Keram. Ges., 1922, 3, 53—64.

AN ordinary refractoriness test and chemical analysis are not sufficient to determine the value of firebricks, particularly those made largely of grog. A normal mixture of 1 pt. of blue clay and 4 pts. of fireclay was ground with water in a ball mill until it passed completely through a 250-mesh sieve. Part of the powder was burned at cone 14, crushed, and separated into grog between 4- and 20-mesh, and grog finer than 7-mesh. Equal parts of grog and the fine raw clay were mixed, made into cubes of 30 mm. side, and fired at cone 14. The cubes were ground accurately to shape, and the "refractoriness under load" determined. This was defined as the temperature at which the cube contracted 0·3% after heating for 2 hrs. under a pressure of 2 kg. per sq. cm. (28 lb. per sq. in.). Similar cubes, but containing varying percentages of silica, alumina, ferric oxide, lime, and magnesia, were also examined. On increasing the silica the minimum refractoriness under load occurred with 60—70% of silica, whereas the minimum refractoriness without load occurred with 90% of silica. On increasing the alumina the refractoriness under load increased steadily up to 80% of alumina, when the test-pieces failed suddenly, probably because there was not sufficient binding clay present. An increase of only 0·64% in the iron oxide (original content of Fe_2O_3 0·89%) reduced the refractoriness under load by 50° C.; with further increase of iron oxide the refractoriness diminished more slowly and remained almost constant between 6 and 12% of iron oxide, after which a further increase caused a further rapid loss of refractoriness. An increase in the lime-content showed a steady and rather rapid loss of refractoriness under load, an increase of only 0·11% of lime (original content of CaO 0·68%) reducing this refractoriness by 25° C. The effect is less noticeable with coarse grog. Magnesia behaves similarly to lime, but the effect of very small percentages of magnesia is greater.—A. B. S.

Refractory materials; Determination of the softening temperature of —— under load. W. Steger. Ber. Deuts. Keram. Ges., 1922, 3, 1—4.

THE test-piece, in the form of a small cylinder, is supported on a refractory cylinder of electrode carbon, 6 cm. diam., and heated in a vertical cylindrical electric resistance furnace, 8 cm. diam., internally, with an e.m.f. of 100—120 volts. A second (hollow) carbon cylinder stands on the test-piece and is provided at its upper end with a plate to which the pressure from a scale-pan carrying weights of 20—100 kg. is transmitted through a simple system of levers. The small movement of the last lever in the series is marked on a rotating drum by means of a light index, about 1 m. in length, which magnifies it 20 times. The hollow carbon cylinder enables the top of the test-piece to be inspected and its temperature to be measured by an optical pyrometer or a thermo-electric couple.
—A. B. S.

Porcelain; Testing of ——. R. Rieke and M. Gary. Ber. Deuts. Keram. Ges., 1922, 3, 5—23.

A CONSIDERATION of the various methods of determining the compressive, tensile, and transverse strengths of materials showed that the following modifications are desirable in applying them to porcelain: Tensile strength.—Instead of the usual flat 8-shaped test-piece, a circular one, 3 in. (7·5 cm.) long and 20 mm. diam. at the middle, corresponding to a cross-sectional area of 3 sq. cm. at the breaking point, is used. The test-pieces are roughly moulded and dried to a black-hard condition, after which they are turned accurately to shape, and burned. They are tested in an ordinary tensile test machine, but the clips are placed at right-angles to each other and are lined with thin copper plates to allow for any irregularities in the test-piece and to ensure its breaking at the centre. Compressive strength is determined in a Gary press in which a disc 10 cm. diam. and 1 cm. thick is supported on a steel ball, 31·7 mm. diam., and pressure applied to it through a second similar ball. The results are calculated to correspond to a disc 1 mm. thick. Transverse strength is determined on a cylindrical test-piece, 120 mm. long and 16 mm. diam., made by extrusion, burnt whilst hanging in a vertical position, and afterwards sawn to the correct length. The test is made in a Frühling-Michaelis apparatus, the test-piece being supported on steel knife edges exactly 10 cm. apart, and loaded centrally. The load is increased at the rate of 1 kg. per sec. Brittleness or resistance to shock is determined in Rudeloff's apparatus, fitted with a Schopper's pendulum impact device, consisting of a pendulum mounted on ball bearings and fitted at its upper end with an indicator to show the angle through which it rotates before its lower end strikes the test-piece. The latter is a rod 120 mm. in length and 16 mm. in diam. The pendulum is raised to a pre-arranged height, and, in falling, it breaks the test-piece and swings forward. The tensile and compressive tests show the most characteristic results, the latter giving figures proportional to, but much larger, than the transverse and brittleness tests. For the determination of porosity an aqueous solution of Brilliant Green is recommended. The sealed pores are estimated by comparing the apparent density of the pieces weighing about 20 g. and the sp. gr. of the finely powdered material. This method ignores the microscopic sealed pores in the minute particles of powder. No relationship between the percentage of sealed pores and the results of other tests could be established. Microscopical examination is used to detect variations in the proportion of unaltered quartz, in the size of the quartz grains and of the pores. The relationship of micro-structure and physical properties needs further investigation, and possibly a microscopical examination may render the other and more tedious tests unnecessary. The results of tests on eight samples of German porcelain (composition not stated) are tabulated. —A. B. S.

Porcelain; Translucency of ——. W. Steger. Ber. Deuts. Keram. Ges., 1922, 3, 50—53.

Hard porcelains of normal composition, made of materials of normal fineness, with low clay-content (40%), and burned at a high temperature (cone 15), vary greatly in translucency, as measured by a photometer. Those containing Norwegian quartz are three times as translucent as those with quartz sand or Taunus geyserite. With a rather higher clay-content (50%) the porcelains containing Norwegian sand are twice as translucent as those with quartz sand, and four times as translucent as those with Taunus geyserite.—A. B. S.

Ceramic tiles; Cold glazes [on cement] and comparison of Kerament slabs with ——. C. Tostmann. Ber. Deuts. Keram. Ges., 1922, 3, 31—41.

Kerament slabs are composed of concrete covered with a glaze by Friedrich's process (G.P. 298,378; *cf.* E.P. 154,236; J., 1919, 47 A). Comparison of purchased slabs of Kerament (each 15×15×1 cm.) with white earthenware tiles (each 14·5×14·5×0·8 cm.) with a transparent glaze, showed that the glaze on the tiles was much harder than the Kerament "glaze"; the latter could easily be scratched with a finger-nail. The porosity after soaking in boiling water was 6·7% for Kerament slabs, and 0·08% for tiles. The samples saturated with water, were exposed 15 times to frost (–15° C.) for 4 hrs., and raised to room temperature after each exposure. All the samples passed this test perfectly. The average transverse strength of the Kerament slabs was 50 kg., that of the earthenware tiles 117 kg., equivalent to a modulus of rupture of 65 and 187 respectively. The samples were laid on a bed of sand and a weight of 0·5 kg. dropped on them from various heights up to 30 cm.; the average resistance was 0·14 m.-kg. for the Kerament slabs, and 0·09 m.-kg. for the tiles. The Kerament slabs were only feebly resistant to acids and were completely destroyed by dilute mineral acids, and attacked by dilute acetic acid, and hence would not be weather-proof. The Kerament "glaze" was too soft to resist any ordinary abrasion, and the surface was not only rough enough to allow any kind of writing upon it, but such writing could be removed. The glazed earthenware tiles, on the contrary, could not be written on, except in a few instances, and, in these, the writing was easily obliterated. The surface of the Kerament slabs could easily be removed by an ordinary wet scrubbing brush, whilst the earthenware tiles were unaffected by such treatment. Kerament slabs are only suitable for situations in which they are protected from all chance of injury, and even then they are far less durable than tiles. Moreover, patina gradually forms on them, and renders them unsightly. The so-called cold glazes may form a substitute for paint, but they cannot in any way replace the glaze on ceramic wares. —A. B. S.

[Opaque] glazes; Zirconium fluoride ——. F. Kraze. Ber. Deuts. Keram. Ges., 1922, 3, 157—161.

Low-temperature glazes, free from lead and boron, rendered opaque by zirconium fluoride, are particularly suitable for fireclays and other porous bodies low in lime. Zirconium compounds do not produce a good opaque white glaze in the absence of fluorides, except at inconveniently high temperatures. The glaze recommended is made from a mixture of sodium silicofluoride, cryolite, soda ash, orthoclase, felspar, quartz, barium peroxide, and zircon, in proportions corresponding to the following formula:—(0·323 Na_2O, 0·412 Na_2F_2, 0·214 K_2O, 0·051 BaO) 0·412SiF_4, 0·234 Al_2O_3, (3·029 SiO_2, 0·184 ZrO_2). In the formula the maximum permissible proportion of zircon is used; part of this may be replaced by cryolite, if desired. In each case, a portion of the kaolin (0·02 mol.) is added after the other materials have been fritted and ground. The fritting must be continued until no more gas is evolved, after which the frit is run into a tank, and allowed to cool slowly; it is then mixed with the reserved amount of clay and ground in a ball-mill. The glazed ware must be placed in the kiln in such a manner that any vapours evolved may readily escape, or the glaze will be soluble in water. The optimum glazing temperature is cone 05a (1000° C.). As enamels on iron, these zircon fluoride glazes are particularly useful, on account of their great elasticity and the rapidity with which they may be fired and cooled.—A. B. S.

Ceramic colours; Constitution of some ——. R. Rieke and W. Paetsch. Ber. Deuts. Keram Ges., 1922, 3, 147—156.

Mixtures of various metallic oxides, in the proportions $1RO:1R'_2O_3$ to $4RO:1R'_2O_3$, were heated for an hour to 600°, 700°, 800° and 1350° C., respectively. The unaltered oxides were separated, and the residual products analysed. It was found that in each case definite compounds of the formula RO, R'_2O_3 were formed, many of them having a characteristic colour, and being very suitable for use as under-glaze colours. Chromites are very stable under glaze, but aluminates and ferrites are dissolved by the molten glaze. With the chromite colours, a glaze with a high alumina content is advantageous, but a high lead content is harmful, causing a partial formation of chromate.—A. B. S.

Patents.

Kilns for clayware; Appliance for the regular and certain firing of top-fired continuous and chamber —— by mechanical means. J. Procter. E.P. 181,090, 3.3.21.

Small coal is fed into the kiln through two or more feed-holes at a time from a central hopper provided with the requisite number of pipes, each pipe containing a screw-conveyor. The hopper is provided with two vertical screw-conveyors, which propel the coal downward through apertures controlled by slides. The rate at which the coal enters the kiln is regulated by adjusting the slides.—A. B. S.

Glass tubes, rods or like bodies; Continuous manufacture of —— [by imparting a rotary movement to the glass during its flow]. Naaml. Vennoots. Philips' Gloeilampenfabrieken. E.P. 172,289, 9.11.21. Conv., 2.12.20.

Glass manufacture [; Press moulding machines for ——]. E. A. Hailwood. E.P. 181,434, 5.3.21.

Bleaching earthy minerals. E.P. 181,132. *See* VII.

IX.—BUILDING MATERIALS.

Concrete pavements; Use of pit-run gravel and excess sand in ——. R. W. Crum. Amer. Soc. Testing Materials, June, 1922. [Preprint.] 10 pp.

Tables of sieving results and graphical representations of numerous tests (compression, transverse and "wear") show that concrete made from pit-run gravel gives results which on the average are closely comparable with those for concrete of the less varied proportions arbitrarily used. As advantages for pit-run mixtures it is claimed that (1) the use of certain coarse aggregates, otherwise unsuitable, is possible; (2) By basing cement required on maximum sand content a factor of safety is provided when sand content drops. Sieve analyses show that lack of uniformity in concrete is no worse with pit-run than with screened aggregates.—J. B. P.

Patent.

Magnesite; Method of treating —— [*for manufacture of oxychloride cements*]. R. D. Pike. E.P. 180,837, 6.4.21.

The free or water-soluble lime in magnesite is reduced to 3% or less by calcining the magnesite, preferably in a rotary kiln, at 800°—950° C., then passing it into a cooler, in which its temperature is reduced to 500°. The product is then treated with a gas (such as lime-kiln gas or flue gases) containing carbon dioxide and a little moisture, which re-carbonates the lime, and renders it insoluble. By this means, a magnesite which would be useless for the production of oxychloride cements (as free lime is injurious) is made capable of producing such cements of first-class quality.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast furnace practice; Little known difficulties occurring through "sulphur-misery" in ——. A. Killing. Stahl u. Eisen, 1921, 42, 968—971.

A furnace yielding an iron with 0·02% of sulphur suddenly began giving an iron with 0·2%. Tough masses of material appeared in front of the tuyères, but were worked away with the aid of bars. After a large number of such difficulties occurring and after changing the tuyères and blowing in sand with the blast and finally removing all deleterious materials such as briquettes, cinders, etc. from the charge, the furnace hearth became clear. Two samples of the slag which had worked into the tuyères gave 5·14% and 4·76% sulphur respectively on analysis. Other tests showed 4—5% of sulphur and the slag remained infusible until the sulphur was lowered below 3%. It is therefore stated that the highest sulphur content permissible in the slag should be 2·5—2·8%. The sulphur in the charge should not exceed 4%.—J. W. D.

Blast furnaces; Processes in gas producers and ——. H. von Jüptner. Z. physik. Chem., 1922, 100, 231—237.

The direct reduction of iron oxide by carbon in the blast furnace is advantageous, for it involves a reduction in the amount of fuel used, but the process is slow. In the electric blast furnace better results are obtained with porous wood charcoal than with the denser coke, and also the fluid condition of the charge accelerates the reduction.—J. F. S.

Cementite; Transformation of —— *at* 210° *C.* G. Tammann. Stahl u. Eisen, 1922, 42, 772—775.

The lines representing the heat content, electrical resistance, and coercivity of steel with different percentages of carbon show a change in direction at the eutectic point. This might be due either to differences in crystal type between pearlitic and primary cementite or differences in grain size. As the magnetic transformation of cementite always takes place at 210° C. and the magnitude of the change increases linearly with the carbon content, the former explanation cannot be the true one. The differences in heat content of pearlitic and primary cementite can only be explained by differences in grain size. Compressing cementite increased the magnitude of the change on loss of magnetisation. On cooling cementite through 210° C. no heat of transformation was detected but a diminution of volume of 0·071 cub. mm. for 1 g. of material. Hence at ordinary temperatures cementite does not interlock closely with the ferrite groundmass. It is possible that by suitable additions the change point could be depressed below ordinary temperature and close interlocking thus produced.—T. H. Bu.

Steels; High-temperature tests on special ——. H. Edert. Stahl u. Eisen, 1922, 42, 961—968.

The tests were carried out on two nickel-chrome steels containing, respectively, C 0·31%, Ni 1·90%, Cr 1·53%, and C 0·21%, Ni 4·03%, Cr 1·69%, a nickel-chrome vanadium steel containing C 4·37%, Cr 2·38%, V 0·58%, and two nickel-chrome steels containing C 0·12%, Ni 1·49%, Cr 15·8% and C 0·28%, Ni 5·76%, Cr 20·6% respectively. The first three were oil-hardened and tempered, the fourth oil-hardened from 900° C. and oil-tempered from 650° C., and the fifth oil-hardened from 1200° C. before testing. Tensile tests were carried out up to 700° C., Brinell hardness tests to 300° C., bending tests to 800° C., and notched bar tests to 700° C. The product of tensile strength and elongation gave high values for all the steels. The increased tensile strength observed in carbon steels between 200° and 300° C. was not noted in these steels. A rapid falling off in strength occurred in the first three steels (pearlitic steels) between 300° and 500° C., but in the higher chromium steels only above 500° C. The higher chromium steels were still bright but slightly yellow after the testing at 700° C. The first three steels possessed a considerable resistance to continued reversal of stress (bending tests) and also to single heavy blows (notched bar tests); they worked easily, especially the first two, and could be used up to 500° C., especially in high-speed machine parts where lightness is essential. The properties of the fourth steel were very similar, and this steel also had great resistance to oxidation and chemical action. It could be used at temperatures up to 600° C. The fifth steel possessed the above properties to a lesser degree, was easily polished, and resisted wear well. At a bright red heat it could be worked similarly to a tool steel and in the cold it could be pressed and drawn fairly well.—J. W. D.

Iron and steel; Influence of molecular concentration on immersion tests on the corrosion of ——. D. M. Strickland. Chem. and Met. Eng., 1922, 26, 1165—1169.

In actual service conditions the corroding medium is generally in excess of the ferrous metal and the molecular concentration remains more uniform than in long period experimental tests. Experiment shows that in a long period test the corrosion of a comparatively resistant metal may approach equality with that of a less resistant metal, owing to the exhaustion of the attacking medium by the latter. Figures are given showing the corrosion rates of iron and steel in various solutions, the solutions being renewed at varying periods. The weight losses were found to be absolutely dependent on the solution strength, and in conducting corrosion experiments it is recommended that all the test-pieces be immersed in one tank of ample capacity, so that the reacting chemical will be present in excess of the ferrous metals. Circulation of the liquor should be provided for, and the results obtained from short period immersions are considered more in line with actual service conditions than are the results from more protracted experiments. Although the experiments primarily show the effect of molecular concentration of the corroding solution, commercially pure iron appears more resistant to corrosion than steel or coppered steel.—C. A. K.

Vanadium; Analytical chemistry of —— with special reference to the investigation of steel works materials. H. Briefs. Stahl u. Eisen, 1922, 42, 775—778.

A process for the separation of chromates and vanadates is described, consisting in the precipitation of vanadium from a boiling solution by means of zinc oxide, the chromate in solution not being affected. The best results were obtained by a double precipitation with zinc oxide. The determination of chromium and vanadium takes 1¼ hr. The method of precipitating quinquevalent vanadium with cupferron (nitrosophenylhydroxylamineammonium) was carefully investigated and accurate determinations of vanadium were made. Cupferron was applied to the analysis of ferrovanadium, and is specially suitable for the separation of quinquevalent vanadium from chromic salts, only one precipitation being necessary. The procedure for the analysis of a chrome-vanadium-tungsten steel is given, involving the use of either the ether process or the barium carbonate process and subsequently separating the chromium and vanadium either by zinc oxide or cupferron.—T. H. Bu.

Chromium in steels; Determination of ——. L. Losana and E. Carozzi. Giorn. Chim. Ind. Appl., 1922, 4, 197—200.

For the determination of chromium in steels good results are obtained by gravimetric methods, but these are too lengthy for industrial use; the employment of colorimetric methods is not recommended. Satisfactory results are yielded by Stead's volumetric method, if certain precautions are taken. In this method the metal is attacked with dilute sulphuric acid (not exceeding 30% in strength) and the solution oxidised with a little nitric acid, boiled until red vapour disappears, diluted to about 500 c.c and boiled for 20 minutes with a large excess of potassium permanganate, the excess of the latter being reduced by addition of a few pieces of filter paper; the paper is found to exert no reducing action on the chromic acid. The liquid is filtered through either asbestos or an alundum crucible under pressure and the chromic acid treated with ferrous sulphate, the excess of the latter being titrated with permanganate. The following modification of the ammonium persulphate method renders it exact and very rapid. The metal is dissolved in nitric acid of sp. gr. 1·2, or, if the content of chromium is high, in 20% sulphuric acid, and the solution diluted and oxidised by means of 20 c.c. of 6% ammonium persulphate solution in presence of silver nitrate, the liquid being boiled until it becomes yellow; if this operation is slow it may be hastened by introduction of a few pieces of filter paper into the liquid. The cold solution is mixed with 25 c.c. of concentrated nitric acid and excess of standard arsenite solution, the excess of arsenite being then estimated by titration with permanganate solution.—T. H. P.

Vanadium in steel; Colorimetric determination of ——. **A. Kropf. Z. angew. Chem., 1922, 35, 366—367.**

A solution of 0·2 g. of a steel containing less than 0·5% V, or 0·1 g. of one containing more, in 3—5 c.c. of a mixture of 9 vols. of sulphuric acid (1:5) and 1 vol. of phosphoric acid (sp. gr. 1·2), is oxidised with 1 c.c. of nitric acid (1:1), boiled, cooled, boiled again after addition of 1 c.c. of 10% ammonium persulphate solution, cooled once more, and transferred to a Nessler tube. 1 c.c. of 3% hydrogen peroxide solution is added and the liquid diluted to 20 c.c. The colour is compared with that obtained by adding known amounts of a standard vanadium solution to a synthetic steel solution of approximately the same content in chromium and nickel as the test, and made by dissolving 0·2 or 0·1 g. of plain carbon steel in the above manner and adding the requisite amounts of standard chromium and nickel sulphate solutions. The vanadium standard is made by dissolving the commercial oxide in caustic potash, acidifying with sulphuric acid, determining the vanadium content of the solution volumetrically and diluting it until 1 c.c. = 0·00005 g. V.—A. R. P.

Dephosphorisation slags; The accessory elements of ——. A. Demolon. Comptes rend., 1922, 174, 1703—1706.

Determinations have been made on a number of slags of the amounts of calcium soluble in different solvents. The solvents used were distilled water, 5% sugar solution before and after calcining the slag, 2% phenol, a neutral solution of ammonium humate, cold solutions of ammonium chloride of different strengths, a saturated solution of carbon dioxide, and mineral acids. The amount of free lime in the slags was small, varying from 1 to 3%. In all the solvents the amount of calcium going into solution increased at first very rapidly with the time of shaking and then only very slowly over a long period of time. This is considered to be due to the presence of calcium silicates which react slowly with the solvents. The amount of magnesium oxide present in the slags varied from 3 to 15%, with an average of 8·9%. The amount of manganese was fairly constant at about 4—5%, which was easily soluble in 2% citric acid.—W. G.

Copper-silicon-aluminium alloys; Physical properties of some —— when sand-cast. E. H. Dix, jun., and A. J. Lyon. Amer. Soc. Testing Materials, June, 1922. [Preprint.] 17 pp.

Tensile tests and micrographic examination were made on a series of aluminium alloys containing 2, 4, and 6% Cu, together with 3, 6, and 9% Si, and also on alloys containing 1% Mn, 2% Cu, and 3, 6, and 9% Si, and the results are reproduced in a series of graphs and photomicrographs. The best physical condition is obtained if the alloys contain from 3 to 5% each of copper and silicon; the lower the copper between these limits the better is the elongation, while if the copper is near 5% and the silicon about 3% the machining qualities are improved. Manganese increases the tensile strength but reduces the elongation, without increasing the tensile strength at high temperatures; with the plain copper-silicon-aluminium alloys the tensile strength decreases very little up to 600° F. (315° C.). The microstructures of these alloys show eutectics of $CuAl_2$ and aluminium and of aluminium and silicon. The iron impurity appears to be present in two forms, as light grey needles of $FeAl_3$ and as irregular grey masses of the so-called "X" constituent. A sixth constituent consisting of bluish-grey cubes has also been noticed in these alloys.—A. R. P.

Lead; Determination of —— in metallic lead by the permanganate method. Y. Odajima. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 270—271.

The sample (2·5 g.) is dissolved in 20 c.c. of dilute nitric acid (1:4); silver, if present, is removed by adding dilute ammonium chloride. The solution is diluted to 200 c.c., filtered, and made up to 500 c.c., to 50 c.c. of which 20 c.c. of saturated oxalic acid or ammonium oxalate solution is added, and then 10 c.c. of acetic acid, with vigorous shaking. After a few hours the lead oxalate is filtered off, washed, and decomposed with dilute sulphuric acid (1:4), the solution diluted to about 200 c.c., heated to 70°—80° C., and the liberated oxalic acid titrated with standard permanganate solution.—K. K.

Metals; Effect of temperature on some of the properties of ——. F. C. Lea. Inst. Mech. Eng., 15.6.22. Engineering, 1922, **113**, 829—832.

In view of the extended use of metals under conditions where they are exposed to high temperatures, *e.g.*, in high-pressure boilers and internal combustion engines, the effect of this treatment on the physical properties of some important metals and alloys has been determined. In the case of "Armco" iron (0·02% C, 0·013% P, 0·043% Mn, and 0·03% S) the ultimate strength falls from 24 tons per sq. in. at −40° C. to a minimum of 19 tons at 0°, then rises in a straight line to a maximum of 39 tons at 220° C., after which it falls to below 2 tons at 850° C. and rises again to 3 tons at 950° C. The elongation decreases from 27% at −50° C. to 13% between 100° and 220° C., then rises to maxima at 400°, 675°, and 800° C., falling to minima at 600°, 730°, and 900° C., at which latter points the metal is very brittle. It is important, therefore, to forge this material at as near 800° C. as possible. The critical points of the metal are at 767° C. and between 880° and 900° C., corresponding with increased brittleness. The elastic limit remains constant to 200° C., then rapidly falls to about one-third of its former value, while the modulus of elasticity decreases regularly with increasing temperature. Carbon steels containing up to 1% C show a similar increase in tensile strength up to a maximum between 220° and 300° C., depending on the carbon content. Similar tests on various steel alloys show that temperatures below 250° C. have no deleterious effects on their tensile properties, but above 350° C. a serious falling off in the elastic properties takes place. Copper-aluminium alloys, on the other hand, while nearly as strong as steel at ordinary temperatures, are considerably less so at 250° C.
—A. R. P.

Metals; Preparation of some special —— by Goldschmidt's aluminothermic process. I. T. Fujibayashi. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 499—511.

An intimate mixture of dried trimanganic tetroxide with 15—20% of its weight of manganese dioxide or sesquioxide, and 90% of the theoretical amount of powdered aluminium was used for the preparation of pure carbon-free manganese. A yield of 85—90% or more of the theoretical was obtained of a purity of 95—97%, the remainder being aluminium, iron, and silicon. For the preparation of pure carbon-free chromium a mixture of chromium sesquioxide with 10—15% of its weight of calcium chromate, and 90% of the theoretical amount of powdered aluminium was heated at 300°—400° C. and reduced as usual. The yield was 85—92% and the purity of the product 95—97%, the remainder being aluminium. Ferrochromium containing about 60% Cr was prepared from a mixture of green chromium oxide with 10—15% of its weight of calcium chromate, the theoretical quantity of black iron oxide, and 85—90% of the theoretical weight of powdered aluminium. The yield was 85—90% of the theoretical, and the product contained 5—8% Al. All the materials for the process should be dried at 200°—300° C., used while still hot, and thoroughly mixed.—K. K.

Metals; Phenomena of diffusion of solid —— and cementation of non-ferrous metals. II. Cementation of copper by means of chromomanganese. G. Sirovich and A. Cartoceti. Gazz. Chim. Ital., 1922, **52**, I., 436—442.

The cementation of copper by chromomanganese containing 30·4% Cr and 63·8% Mn has been studied by means of the arrangement previously used (*cf.* J., 1922, 17 A). The chromium does not penetrate the copper, but it influences the migration of the manganese to a much greater extent than the iron of ferromanganese does. (*Cf.* J.C.S., August.)—T. H. P.

Tellurium-lead and tellurium-antimony-lead alloys. M. Dreifuss. Z. Elektrochem., 1922, **28**, 100—101, 224.

When lead is added to molten tellurium in small quantities, a little of the tellurium alloys with the lead, but a large portion forms a slag containing both elements. Tellurium has a deoxidising action on lead, so that the alloy may be heated to redness without the surface losing its brightness. Tellurium and antimony form a continuous series of mixed crystals, and alloys containing tellurium and lead may be prepared by mixing tellurium with molten antimony, and adding to the molten alloy thus obtained first small quantities of antimony-lead alloy and eventually pure lead. A stiff pasty mass is obtained which on heating to 700° C. melts and does not readily lose its bright surface. In the same way small quantities of tin and copper alloy with the antimony-tellurium alloy. The addition of 2% of tellurium to lead-antimony alloys has no marked effect on the hardness. The addition of 5—6% of tin to antimony-lead alloys produces much more desirable properties than does tellurium.—J. F. S.

Uranium; Qualitative test for ——. H. D. Buell. J. Ind. Eng. Chem., 1922, **14**, 593.

Uranium may be detected in slags or ores by preparing a nitric acid solution of the material, too great an excess being avoided, and adding an excess of granulated zinc. When the reaction with the acid has subsided a yellow deposit will appear on the zinc if uranium is present. Gold, platinum, thorium, lead, tungsten, titanium, chromium, mercury, and copper do not interfere with the test. Iron and vanadium interfere only when present in large quantities, and in that case the spent liquid is removed and the zinc and the deposit are again treated with nitric acid. The deposit dissolves, but reappears when the acid is again exhausted, and vanadium and iron remain in solution. The test is not applicable in the presence of sulphuric or hydrochloric acids. The yellow deposit is apparently the hydrated trioxide $VO_3,2H_2O$.—G. F. M.

Bismuth and cadmium; Solubility in the solid state of —— in lead. C. Di Capua. Atti R. Accad. Lincei, 1922, **31**, I., 162—164.

The solid solubility of lead in bismuth is 4% and that of bismuth in lead 34%. For lead in cadmium or cadmium in lead the solid solubility is practically zero.—T. H. P.

Minerals; Heavy liquids for the separation of ——. E. Clerici. Atti R. Accad. Lincei, 1922, 31, I., 116—118.

For the mechanical separation of minerals of different densities, the following colourless liquids, which may be diluted and are recoverable, are recommended: Aqueous barium bromomercurate solution, sp. gr. 3·11 at 11° C., 3·14 at 18° C.; saturated aqueous thallium formate solution, sp. gr. 3·31, 3·40, and 4·10 at 10°, 20°, and 50° C. respectively; aqueous solution of thallium formate and thallium malonate in equal proportions, sp. gr. 4·0, 4·7, and above 5 at 10°, 50°, and about 100° C., respectively. Fused thallium formate, either alone or mixed with fused thallium malonate, may also be used. A solution of powdered thallium carbonate in fused thallium formate has sp. gr. above 5.—T. H. P.

Patents.

Copper alloys; Process of manufacture of ——. O. von Rosthorn, Assee. of A. Heller. E.P. 158,882, 4.2.21. Conv., 4.2.20.

A more uniform quality of bronze for electrical purposes is produced by the use of an intermediate alloy containing about 1 pt. of tin, 3 pts. of cadmium, and 2 pts. of copper. Final adjustment of the composition is obtained by the addition of an auxiliary alloy consisting of equal parts of tin and aluminium, or of tin and magnesium (or cadmium). —C. A. K.

Non-ferrous metal articles having an electrically insulating and mechanically adhesive coating. Producing an electrically insulating and mechanically adherent coating on metal articles. F. Krupp A.-G. E.P. (a) 168,592, 11.8.21, and (b) 172,620, 25.11.21. Conv., (a) 3.9.20, (b) 13.12.20.

(a) Non-ferrous metal articles are pickled by treatment with a 5—10% solution of mineral acid or 10% solution of iron chloride, and then immersed in a bath, heated to 80°—100° C., composed of an aqueous solution of potassium permanganate acidified with sulphuric acid, and containing in addition a small amount of iron, lead, silver, or similar metallic salts. These latter may likewise be added to the pickling solution. (b) In the production of the adherent coating in accordance with (a), the loose layer simultaneously produced is not removed, but saturated with a drying oil, *e.g.*, linseed oil or resin solutions. If desired, the thickness of the loose layer deposited may be increased by adding a soluble organic compound, *e.g.*, sugar, to the pickling solution.—J. S. G. T.

Magnetic separators. H. H. Thompson and A. E. Davies. E.P. 178,587, 27.1.21.

One or more arcuate or segmental stationary armature pieces are arranged partially to surround a drum or ring and concentric therewith. The armature pieces can be adjusted radially so as to vary the air gap formed with the drum or ring, and also adjusted circumferentially according to the material under treatment. The material may be fed on to the separating drum or ring through slots in the armature pieces.—T. H. Bu.

Metallurgical furnaces; Gas-fired ——. South Metropolitan Gas Co., and D. Chandler. E.P. 178,722, 22.4.21.

The furnace is of the reverberatory type, the products of combustion being led in through the roof and tangentially to the hearth. After flowing over the hearth in one direction they flow back in the opposite direction over a sloping floor leading to the hearth and thence to a flue passing beneath the floor, but stopping short of the hearth.—T. H. Bu.

Shaft furnaces, especially blast furnaces; Process for the working of ——. E. Diepschlag. E.P. 180,395, 11.2.21.

Dust-like fuel, ores, mouth-dust and the like, are supplied to the smelting zone of the furnace through drop-feed pipes leading to the air nozzles. The height of the column of material in the feed pipes is such that the pressure exceeds that in the furnace. The operation of the furnace can be simply controlled by variation of the air supply and adjustment of slide-valves or the like in the feed pipes.—J. W. D.

Shaft-furnaces, gas producers, and the like; Feeding of fine materials to ——. E. Diepschlag. E.P. 180,396, 11.2.21.

Fine substances, *e.g.*, fuel, or ore and fuel, are introduced into the mouth of the furnace as part of a charge and are carried away by the furnace gases to a collector, where they are dried by the heat of the furnace or by heat from an outside source such as a hot current of waste gases from metallurgical furnaces or gas engines. The dryer, in the form of a tube with a revolving screw conveyor, or a revolving drum, may be inserted in the waste gas flue of the furnace.—J. W. D.

Blast furnace operations; Process for conveying the mouth-dust and other fine ores in ——. E. Diepschlag. E.P. 180,397, 11.2.21.

Air or gas under pressure is used to transport the materials, which are of such a degree of fineness that the gas forces a passage through and loosens the mass, and carries the material forward. The apparatus consists of a closed receptacle, a delivery pipe having an inlet adjacent to the bottom of the receptacle, and an outlet at the point of discharge, and means for introducing a gas under pressure into the receptacle. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 132,523 and 135,842.)—J. W. D.

Open-hearth furnace device. A. Arthur. U.S.P. 1,414,451, 2.5.22. Appl., 7.2.21.

A gas slag pocket and an air slag pocket are separated by a partition provided with a series of tortuous paths, from which an air passage leads to openings on each side of a gas port. The paths may be used alternately.—T. H. Bu.

Metals from their compounds; Methods of extraction of ——. P. Freedman and E. Greetham. E.P. 180,384, 26.1.21.

The compounds are fused and reduced in a direct current arc furnace in an atmosphere of inert gas or gases, such as argon or helium. The furnace is so constructed that it can be exhausted to a high degree of vacuum before introducing the inert gas. The compound to be reduced, *e.g.*, the oxide of zirconium, cerium, uranium, or other rare metal, is contained in a crucible of refractory conducting material, *e.g.*, tungsten, which serves as anode, and the compound under treatment is rendered conductive by being heated in an arc formed between the wall of the crucible and the cathode (a rod or block of tungsten or other suitable material), or between an auxiliary anode and the cathode. The inert gaseous atmosphere in the furnace is continually changed, the gases being drawn out of the furnace into an external reservoir and returned to the furnace after passing through purifying devices to remove active gaseous impurities.—J. W. D.

Ores or metallurgical products; Preparatory treatment of ——. O. Imray. From Jackson and Co. E.P. 180,968, 27.4.21. Addn. to 172,356 (J., 1922, 107 a).

After the nitrate roast, as described in the chief patent, the hot ore is sprayed with a solution of, or mixed with, a solid, metal halide, *e.g.*, sodium chloride, and the roasting is continued for a further short period.—A. R. P.

Lead-bearing mattes and the like; Treatment of ——. F. E. Elmore, and The Chemical and Metallurgical Corp., Ltd. E.P. 181,239, 11.6.21.

Lead-bearing mattes or products consisting essentially of metallic sulphides are pulverised and treated with a hot concentrated chloride solution (*e.g.*, sodium chloride), which has been acidified with hydrochloric or sulphuric acid, or with an alkali bisulphate. The filtered solution contains all the lead and a proportion of the silver present, which are recovered by known methods. The method is particularly applicable to "leady-copper mattes."—C. A. K.

Metallic values from slag; Recovery of ——. H. V. Welch, Assr. to International Precipitation Co. U.S.P. 1,414,491, 2.5.22. Appl., 7.9.20.

The slag is brought into contact with a halidising agent in the presence of an oxidising atmosphere at a sufficiently high temperature to cause the metals in the slag to vaporise in the form of halide compounds.—T. H. Bu.

[*Zinc*] *ore briquette.* D. B. Jones. U.S.P. 1,415,094, 9.5.22. Appl., 3.6.18.

The briquette is composed of zinc ore, a reducing agent, and bauxite as binder.—T. H. Bu.

Metallurgical apparatus. J. Lund. U.S.P. 1,415,183, 9.5.22. Appl., 8.8.18.

A molten bath of metal is maintained in a chamber to which heat can be applied both from above and below. Solid material and molten slag are fed simultaneously into the chamber, and the protective coating of molten slag may be supplied, maintained, or withdrawn as desired.—T. H. Bu.

Metal scavenging alloy; Process of making and using ——. H. G. C. Thofehrn (D. H. McLean, administrator), Assr. to Light Metals Co. U.S.P. 1,415,733, 9.5.22. Appl., 2.2.20.

Ferro-uranium and aluminium are melted together, and the molten material separated from the slag and allowed to cool.—T. H. Bu.

Iron and steel; Process for rust-proofing articles of ——. E. P. Andrews. E.P. 181,399, 2.12.20.

See U.S.P. 1,362,213 of 1920; J., 1921, 88 A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 862 of 1876, 94 of 1897, 15,852 of 1912, and 129,831.)

Iron or steel; Process of making ——. L. P. Basset. U.S.P. 1,419,801, 13.6.22. Appl., 4.6.19.

See E.P. 130,610 of 1918; J., 1921, 588 A.

Molybdenum metal or iron molybdenum alloys; Process for the manufacture of ——. Ampère-Ges.m.b.H., F. Rothe and O. Diefenthäler. E.P. 160,143, 12.3.21. Conv., 12.3.20.

See G.P. 337,961 of 1920; J., 1921, 663 A.

Electric furnaces. E.P. 170,848. *See* XI.

XI.—ELECTRO-CHEMISTRY.

Graphite; Electrical conductivity of compressed ——. E. Ryschkewitsch. Z. Elektrochem., 1922, 28, 289—298.

Bavarian graphite has the highest electrical conductivity of all varieties of graphite. The specific conductivity of graphite increases with increasing pressure according to a hyperbolic law. All varieties of graphite approach a common value of 0·0075 ohm for the specific resistance with increasing pressure. The relation between the specific resistance, y, and the pressure, x, is expressed by the formula, $y = a/x + 0{\cdot}0075$, where a is a constant. —J. F. S.

Alkali chloride; Model apparatus for the electrolysis of —— *with mercury cathodes.* A. von Antropoff. Z. Elektrochem., 1922, 28, 298—300.

A glass apparatus, for demonstrating the electrolysis of solutions of alkali chlorides, is described. —J. F. S.

Carbon monoxide-oxygen cell with glass as electrolyte. H. Kallmann. Z. Elektrochem., 1922, 28, 81—85.

The emf of cells containing various mixtures of carbon monoxide, carbon dioxide, and oxygen on one side of a glass wall and air on the other, have been determined at 717° C. and under pressures of 800—920 mm. The values obtained agree to 0·9% with the theoretical values calculated from the equation

$$E = 1{\cdot}118 - 0{\cdot}0707 \log p_{CO_2}/p_{CO}\cdot p_{O_2}^{\frac{1}{2}}$$

—J. F. S.

Electrochemical oxidation of organic compounds. E. Müller. Z. Elektrochem., 1922, 28, 101—106.

The assertion of Fichter (J., 1922, 20 A) that his views on electrochemical oxidation and those of the author are in agreement is not true. Whilst the author assumes the discharge of anions, Fichter supports the primary formation of oxygen and the accompanying purely chemical oxidation. He also assumes the intermediate formation of peroxides or per-acids, but does not explain how they are formed and decomposed. Such per-compounds may be prepared chemically, but their decomposition is to some extent different from what would be expected if they are formed at the anode and form the products of electrolysis. The author accepts the formation, by the discharge of anions, of intermediate hydroxy-compounds, which decompose in a manner in keeping with facts, and which present a mechanism for both chemical and electro-chemical oxidation.—J. F. S.

Electric furnaces. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Ind.-Hypotekbank. E.P. 170,848, 24.10.21. Conv., 1.11.20.

An electric furnace is provided with a continuous electrode, either hollow or channelled longitudinally, manufactured according to E.P. 116,853 and 137,811 (J., 1918, 429 A; 1920, 374 A). Conducting material is fed into the furnace through the electrode, and current passing between the material and the electrode is employed to bake the electrode. The internal cross-sectional dimensions of the furnace are small compared with the diameter of the hollow electrode. The funnel or crater at the lower end of the electrode forms a roof over the region of great heat development. Coke, or similar material, and ore to be treated are charged round the electrode, and air or other oxidising gas blown into the charge at a suitable height, the resulting carbon monoxide being used to preheat a further charge.—J. S. G. T.

Electrolyte; Storage battery ——. F. de W. Cheney. E.P. 181,630, 26.7.21.

An electrolyte for use in storage batteries is prepared by dissolving 4 oz. of sodium phosphate in 1 quart of water, and adding 1 quart of chemically pure sulphuric acid.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Alligator and crocodile oils. S. Kobayashi. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 691—703.

The oil obtained from a north African alligator (*Alligator mississipiencis*) by boiling was a light yellow liquid having a peculiar fishy odour and deposited a large quantity of stearine on standing. Its characters were: Sp. gr. (15°/4° C.) 0·9285; iodine value (Wijs) 159·1; acid value 1·2; saponification value 189·2; n^{20}=1·4795; unsaponifiable matter 0·73%. The fatty acid bromide from the saponified oil yielded 20% of solid acid on distillation by Grün and Janko's method; 25·1% of highly unsaturated acid (iodine value 367·6) was obtained by Tsujimoto's lithium salt acetone method. The debrominated acid from the ether-insoluble polybromide (12%) appeared to consist of a mixture of arachidonic and clupanodonic acids. The debrominated acid (iodine value 308·0, neutral. value 165·7, n^{20} 1·4888) from the petroleum ether-insoluble bromide (7%) had the composition $C_{22}H_{34}O_2$, and gave on hydrogenation an acid of m.p. 76°—76·5° C. and neutral. value 165·1. The lower unsaturated acids consist mainly of oleic and palmitic acids with small quantity of lower fatty acids. The unsaponifiable matter (0·7%) is mainly cholesterol. Crocodile oil from an African crocodile (*Crocodilus niloticus*) was a solid fat at room temperature, having sp. gr. (40°/4° C.) 0·8989; m.p. 30°—33° C.; acid value 2·1; saponification value 195·4; iodine value 60·3; n^{40} 1·4602; and unsaponifiable matter 0·97%. The lead salt ether method yielded about equal quantities of a liquid acid (iodine value 92·6) and a solid acid (m.p. 52·5°—53° C., iodine value 6·1), the former consisting mainly of oleic acid and the latter of palmitic and stearic acids. A small quantity of highly unsaturated acid was also present.—K. K.

Shark, ray, and chimæras liver oils. M. Tsujimoto. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 252—270.

The specific gravities (15°/4° C.), saponification, iodine (Wijs), and acid values, refractive indices at 20° C., quantity of unsaponifiable matter, melting points of fatty acids, quantity of fatty acid polybromides, and bromine contents of polybromides have been determined on the liver oils from the following sharks, rays, and chimæras. *Sharks:* Tobi-mizuwani, *Carcharias owstoni* (Garman); Kiku-zame, *Echinorhinus brucus* (Bonnaterre); Koma-mizuwani, *Carcharias ferox* (Risso); Itachi-zame, *Galeocerdo tigrinus* (M. and H.); Mejiro-zame, *Carcharias gangeticus* (M. and H.)?; a shark the name of which has not yet been determined, probably a species of Abura-zame; Shimaneko-zame (striped cat-shark), *Heterodontus zebra* (Gray); Tsumari-tsuno-zame, *Squalus mitsukurii* (Jordan and Snyder); Shiro-zame, *Cynias griseus* (Pietschmann); Kirinoto-buka, *Orectolobus japonicus* (Regan); Eiraku-buka, *Galeorhinus japonicus* (M. and H.); Ushimi-zuwani, *Carcharias taurus* (Rafinesque); and Koro-zame, *Squatina nebulosa* (Regan). *Rays:* Yamato-shibire-ei (great torpedo-fish), *Narcacion tokionis* (Tanaka); Nitari-ei, a species (?) of *Dasyatis;* Komon-sakata-zame, *Rhinibatus polyphthalmus* (Bleeker); and Tongari, *Rhyncobatus djiddensis* (Forskal). *Chimæra:* Owston-ginzame, *Chimæra owstoni* (Tanaka). Squalene was detected in Tobi-mizuwani (65·9%), Kiku-zame (53·5%), and Koma mizuwani (35·6%), but not in the other oils.
—K. K.

Arachis oil; Catalytic decomposition of ——. A. Mailhe. Bull. Soc. Chim., 1922, 31, 567—570.

When arachis oil is passed over an alumina-copper catalyst at 600° C. and the product freed from acids and then hydrogenated over nickel at 180°—200° C. hydrocarbons of the methane and benzene series are obtained. Amongst the aromatic hydrocarbons benzene, toluene, and *m*-xylene were identified.
—W. G.

Erucic acid and its anhydride. III. D. Holde and C. Wilke. Z. angew. Chem., 1922, 35, 289—291. (*Cf.* J., 1922, 260 A.)

A detailed account is given of the methods tried and that finally adopted for the preparation of pure erucic acid from rape oil. The fractional distillation of the esters obtained by the methylation of the oil gave a methyl erucate from which an erucic acid was prepared having the correct m.p., 34° C., and the correct molecular weight by titration, but an iodine value of 71—72, indicating the presence of about 5% of saturated acids. Attempts to separate these saturated acids by extraction of the lead salt with ether, light petroleum, or chloroform failed, the whole of the salt passing into solution. Neither could the iodine value of the impure erucic acid be raised by fractional precipitation of a preparation (previously partially purified through the methyl ester and crystallisation from alcohol) with lead or magnesium acetate. The pure acid with an iodine value of 75 was eventually obtained by recrystallising crude erucic acid from alcohol, first at temperatures below 0° C. to remove the liquid unsaturated acids, and then above 0° C. to remove the greater part of the saturated acids, and finally fractionally precipitating this product with a saturated alcoholic solution of lithium acetate, whereby the saturated acids were precipitated first. The pure acid had m.p. 33·5° C. Erucic anhydride was prepared by heating the acid with acetic anhydride at 170° C. under pressure for 7 hrs. After purification it formed a white crystalline substance, m.p. 46° C. It is decomposed by boiling water, boiling alcohol, and cold alcoholic alkali hydroxide solution, but is stable towards cold aqueous alkali and dilute hydrochloric acid.—G. F. M.

Pine needles; A variety of wax from —— and certain abietic esters. H. P. Kaufmann and M. Friedebach. Ber., 1922, 55, 1508—1517.

The dried residue left after the distillation of pine needles with steam is extracted with ether, benzene, and carbon bisulphide, thereby giving a dark green viscous mass, the weight of which does not exceed 8—10% of that of the crude material and varies greatly with the season of the year. This residue is extracted with cold acetone in which the wax does not dissolve; the undissolved portion is distilled under diminished pressure and the distillate is crystallised repeatedly from alcohol or acetic acid. The chief components of the wax (m.p. 64°—65° C.) thus isolated are cetyl, ceryl, and myricyl alcohols, which are mainly esterified with stearic and palmitic acids; in addition, the presence of hydroxypalmitic and abietic acids has been established, the latter being in the form of an ester. The fat-like product which is dissolved by cold acetone (see

above) contains mainly phytosterol and oleic acid. Cetyl abietate is a wax-like substance, m.p. 40° C., whereas myricyl abietate is a dark brown, brittle product closely resembling shellac. The difficulties involved in the separation and the small yields of the wax render the technical utilisation of pine needle residues in this manner unpromising.
—H. W.

Soap solutions; Studies of the constitution of ——. Sodium behenate and sodium nonoate. O. J. Flecker and M. Taylor. Chem. Soc. Trans., 1922, **121**, 1101—1109.

Sodium behenate solutions exhibit the same type of dissociation as the palmitate and stearate (*cf.* McBain, Laing, and Taylor, J., 1922, 424 A). Although in very high concentrations of any of the soaps there is but little difference in the amounts of neutral colloid and ionic micelle, which constitute almost the whole of the solution, these persist in much more dilute solutions in the case of the behenate. The nonoate, as typical of fatty acids with an uneven number of carbon atoms, exhibits properties intermediate between those of the adjacent members with an even number of carbon atoms.—G. F. M.

Water-in-oil type emulsion; Formation of a —— by the concentration of the oil phase. R. P. Sanyal and S. S. Joshi. J. Phys. Chem., 1922, **26**, 481—486.

The authors have confirmed the result that emulsions of the water-in-oil type can be formed by shaking large quantities of a viscous oil (olive oil, castor oil) with soap solutions. When the concentration of the emulsifying agent exceeds about 1% oil-in-water emulsions only are stable. In the case of light oils (kerosene, benzene) the water-in-oil type emulsion is unstable.—J. S. G. T.

Patents.

Oil presses and the like. Utrechtsche Machinefabriek opgericht door F. Smulders. E.P. 156,593, 6.1.21. Conv., 8.4.19.

A cage press having a floating press chamber is provided with a filling drum and a pressing block, these being adapted to be alternately moved laterally into the space between the piston and the press chamber. The press has a telescopic outer piston transmitting its pressure to the inner piston. The pressing block, which has a smaller cross-sectional area than the inner space of the press chamber, is placed on the inner piston, and the filling drum fits between the press chamber and the outer piston, the length of stroke and the diameter of the latter being such that after the removal of the filling drum the outer piston can rise until it abuts against the press chamber. One or more removable distance pieces fit between the wall of the press chamber and the head of the press, and there is an independently removable counter-pressure block.—H. C. R.

Oils; Process or method of refining ——. M. Reynolds. U.S.P. 1,419,760, 13.6.22. Appl., 4.3.20.

Discoloured oils are brought to a desired standard of colour by alternately refining, by a process including saponification, and bleaching the oil.
—L. A. C.

Detergent compound and method of making the same. F. H. Guernsey, Assr. to The Electric Smelting and Aluminum Co. U.S.P. 1,419,625, 13.6.22. Appl., 18.2.21.

A hydrated detergent contains 1 mol. of alumina, x mols. of silica, and $x-1$ mols. of an alkali metal oxide (where x is greater than 7), together with an alkali metal salt of a weak acid, an emulsifying agent, and a further quantity of an alkali metal oxide sufficient to replace that consumed during the cleaning process, but small enough to enable the product to remain solid at summer temperatures.
—L. A. C.

Oils; Method for deodorising blown or polymerised vegetable or animal ——. E. I. du Pont de Nemours and Co., Assees. of J. E. Booge. E.P. 157,401, 10.1.21. Conv., 13.6.18.

Edible fats. E.P. 181,077. *See* XIXA.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Yield value and mobility of paints; Relation of —— to their so-called consistency. J. E. Booge, E. C. Bingham, and H. D. Bruce. Amer. Soc. Testing Materials, June, 1922. [Preprint.] 40 pp.

Fifty-two samples of 13 commercial paints were examined in the plastometer designed by Bingham and Green (J., 1920, 495 A), and the results compared with the average values awarded by a committee of seven paint experts acting as five independent observers, in an empirical notation of units of consistency, *i.e.*, "consistencies" on the thick side being represented by the units 1, 2, 3, etc., and on the thin side by −1, −2, −3, etc., the best painting consistency being designated as zero. The plastometer used differed from that described in the later papers of Bingham and his collaborators in the use of a simpler pressure stabiliser, and in the direct weighing of the material exuded from the capillary, in place of either the drop counting method or the flowmeter reading. The accuracy of the plastometer in furnishing reproducible results is confirmed, and the non-dependence of yield value on the dimensions of the capillary used is noted. Comparison of the average of the "consistency" values with the two factors of mobility (reciprocal of viscosity in dynes per cm.), and yield value (expressed in g. per sq. cm.) showed no simple relationship, but complete correlation was shown in the two sets of figures except in one case. The clearest and most simple relationship, however, was obtained by plotting the ratio of the quotient of mobility into yield value (f/μ) against consistency, when 12 out of the 13 paints examined lay fairly close to a smooth curve, the exceptional case being represented by an enamel containing a vehicle with abnormally low fluidity.—A. de W.

Paints; Physical properties of ——. P. H. Walker and J. G. Thompson. Amer. Soc. for Testing Materials, June, 1922. [Preprint.] 19 pp.

Uniform films for tests are obtained by flowing an excess of the paint under examination on to the centre of the finely-ground face of a circular glass plate 25 cm. in diam. and 1 cm. thick, mounted horizontally on a vertical spindle rotating at *e.g.*, 300 r.p.m. Distribution is complete, and all excess thrown off the plates after 3 minutes' rotation, a film of practically uniform thickness being obtained excepting for a small pyramid in the centre in the case of paints or enamels. This procedure permits of paint mixtures being made and so diluted with volatile solvents, that films of uniform and similar thickness are obtainable by the usual methods of brushing etc., it being assumed that mixtures which give films of similar thickness when whirled as described will also give similar films when brushed on test panels. The mobility of mixtures of linseed oil and turpentine was found not to be a linear function of the composition, and this result was confirmed by experimental determinations of viscosities of mixtures of linseed oil and turpentine in varying proportions, a hyperbolic curve being obtained. On application of a paint obtained by freshly mixing new or old white lead ground in oil with raw linseed oil, spots or pits consisting of small areas from which pigment is repelled appear on the surface. The trouble is obviated by storage for a period of 24 hours before use, by substitution of boiled linseed oil in place of raw oil, or by the use as a thinner of a raw linseed oil previously treated with white lead. The trouble does not occur when other pigments are substituted for white lead or when other oils are used for thinning; it is not due to faulty incorporation, presence or absence of driers or thinners, presence of free fatty or mineral acids or water, and the authors assume that the governing factor consists in a reaction between basic carbonate white lead and some unidentified portion of the oil.—A. de W.

Paints; Accelerated weathering of —— on wood and metal surfaces. H. A. Nelson. Amer. Soc. for Testing Materials, June, 1922. [Preprint.] 15 pp.

Accelerated weathering tests for paint films have been carried out in a wooden exposure tank surrounded by an insulated air space and lined with galvanised iron. Effects of sunlight, rain, and mist have been simulated by a quartz mercury arc lamp of 30 in. effective lighting length, a revolving spray, and a water atomiser respectively, a variable speed electric fan serving to cool the arc and maintain a uniform temperature. A cycle of exposure for 24 hours to the rays of the arc at a temperature of 50°—60° C., followed by cooling and exposure to the water spray for a further 24 hrs. at 5°—10° C. was chosen as representing actual service conditions. Exposures were made at a distance of 28 in. from the source of the rays, investigation proving that the useful rays of destructive effect had a wave-length in the neighbourhood of 3000 A.U. On an average, comparable results were obtained in as many days in the apparatus as in months under service conditions. The following results were obtained on a series of paints, the figures referring to the number of days necessary for the complete loss of gloss, and initial chalking, respectively: 100% lead-free zinc oxide, 14, 16; 100% leaded (35%) zinc oxide, 9, 12; 100% light-resistant lithopone, 4, 6; 100% basic lead carbonate, 3, 5; 100% "Titanox," 2, 4; 40% zinc oxide, 40% lithopone, 20% whiting, 9, 11. The effect of periodic saturation and maintenance of a saturated atmosphere during exposure is to accelerate both complete loss of gloss and initial chalking by 50%, a fact attributed to the activity of dissolved oxygen in an ionised condition. Freezing of a saturated film materially promotes the formation of removable "chalk," most probably due to the formation of ice within the film. Neither flaking nor "checking" has been reproduced in any of the tests. Cracking, rapidly followed by scaling and peeling, is produced by periodic exposures to temperatures considerably below freezing-point, and is reproducible by exposures of equal alternate intervals to light, low temperature, and water-spray for a period of 100 days, equivalent to 14—15 months' exposure to the weather. Lack of adherence is a fault more strictly connected with the method of application of the paint, but can be reproduced by exposure at 50°—60° C. to the mercury arc. Of commercial paints intended for use as protective coatings for iron, both the combination of 83% Fe_2O_3 with 15% ZnO, and a 100% red lead paint showed outstanding merit in maintaining gloss and inhibiting the formation of rust as compared both with iron oxide paints reduced with various fillers, and a reduced ZnO/sublimed lead paint. Whilst a certain light-resistant lithopone maintained its whiteness over a period of 3 years on exterior exposure, the effect of the ultra-violet radiations was to discolour both this product and white lead in a short time.—A. de W.

White pigments; Determination of tinting strength of —— by the Pfund colorimeter. J. H. Calbeck and C. P. Olander. Amer. Soc. Testing Materials. June, 1922. [Preprint.] 8 pp.

A given amount of lampblack is ground with a definite quantity of white pigment, glycerin being used as a medium, and the resulting loss in brightness is measured on a Pfund or other colorimeter. The reading obtained is then referred to that amount of stainer necessary to produce the same brightness with the standard white pigment, such readings being previously plotted on a chart correlating decreasing brightness of the standard with increasing additions of stainer. The true strength measurement, however, is obtained by a modified treatment wherein a correction for the differing initial brightness of the sample is allowed for by similar reference to the standard strength curve. Since the standard strength curve is not a straight line but indicates that the greatest loss in brightness takes place with the initial additions of stainer, the maximum sensitiveness of the determination will be obtained by the addition of relatively small proportions of stainer.—A. de W.

Wax from pine needles, and abietic esters. Kaufmann and Friedebach. *See* XII.

Patents.

Lead sulphate water paste; Conversion of —— into oil paste. D. Whyte. U.S.P. 1,419,655, 13.6.22. Appl., 27.6.21.

Lead sulphate water pastes are dried to express the "free water" and then churned with oil in just sufficient amount to "break out the waters of crystallisation" from the lead sulphate particles and to be taken up by these particles to form a stiff paste.—A. de W.

Pigment colours [green lakes]; Manufacture of ——. J. Y. Johnson. From Badische Anilin und Soda Fabrik. E.P. 181,584, 20.5.21.

Nitroso-β-naphthol, preferably in the form of the bisulphite compound, is caused to react with ferric or ferrous salts, in which latter case (with the exception of pyroligneous iron liquor) the iron is employed in less than the theoretical amount of two mols. of nitroso-β-naphthol to each atom of iron. The reaction is preferably carried out in the presence of Turkey-red oil or similarly acting substance, *e.g.*, sodium di-isopropylnaphthalenesulphonate, and the mixture should be kept alkaline either from the beginning or at the end of the reaction.—A. de W.

Artificial resin products; Manufacture of ——. H. Dreyfus. E.P. 181,575, 12.5.21.

Cyclohexanone or one of its homologues is condensed with acetaldehyde in the presence of either alkaline or acid condensing agents. The ratio of acetaldehyde to cyclohexanone may vary from one to several mols., whilst the temperature of reaction and dilution by means of solvents may also vary within wide limits; *e.g.*, 100 pts. by weight of cyclohexanone is diluted with 100 pts. by weight of alcohol, and 1 pt. by wt. of caustic soda as a 50% solution added whilst cooling. The mixture is heated to 80°—90° C., about 250 pts. by wt. of 25% acetaldehyde added, and the mixture heated for 3—4 hrs. The alcohol is then distilled off, the residue washed with water and allowed to solidify by standing.—A. de W.

Bleaching earthy minerals. E.P. 181,132. *See* VII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Tests on plantation —— with zinc oxide and litharge mixings. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 275—281.

Samples of rubber prepared in slab form using varying proportions of acetic acid, sulphuric acid, and alum as coagulants, were vulcanised for 3 hrs. at 138° C. with sulphur alone (proportions 90:10) or with the additional presence of zinc oxide (proportions 90:10:5) or of litharge (proportions 100:6:7). For each sample of rubber the elongation measured at 0·6 kg. per sq. mm. for the simple mixture stood in an approximately constant ratio to that of the mixture with zinc oxide but not to that of the litharge mixture; constant relationship, however, did not extend to the corresponding vulcanisation coefficients, the zinc oxide and litharge mixtures exhibiting relatively higher values for the more slowly vulcanising rubbers.
—D. F. T.

Accelerating effect of dimethyldithiocarbamate of dimethylamine and of diethyldithiocarbamate of diethylamine; Note on the comparative ——. P. Schidrowitz, J. M. S. de Gouvea, and F. G. Osborne. Indiarubber J., 1922, 64, 75—77.

The vulcanisation of mixtures of rubber (100) and sulphur (8) with and without the addition of zinc oxide (10) at 286° F. (141° C.) showed that dimethylamine dithiocarbamate (0·25) and its diethylamine analogue are of comparable effectiveness in the absence of zinc oxide. In the presence of zinc oxide the dimethylamine compound is distinctly the more active. An iodine derivative of the dimethylamine compound proved distinctly less active than either. (*Cf.* Twiss, Brazier, and Thomas, J., 1922, 81 T.)—D. F. T.

Rubber goods; Accelerated ageing tests on ——. W. W. Evans. Amer. Soc. Testing Materials, June, 1922. [Preprint.] 10 pp.

In accelerated ageing tests at 160° F. (91° C.) in circulating fresh air the samples do not harden as in natural ageing but become definitely weaker; the stress-strain curves undergo little alteration in form but become shortened and also gradually fall lower on account of increasing resistance to extension. Sulphur changes are noticeable but are unimportant. The results are best interpreted by comparison of the curves showing the progress of the ageing effect in samples of similar type. The curves for the accelerated and natural life tests are not exactly parallel, the former test being somewhat the more severe, even when interpreted on the basis that one day of accelerated ageing is equivalent to six months' natural life. In the vast majority of cases too rapid deterioration is due to over- or under-vulcanisation, chiefly the former. (*Cf.* Geer and Evans, J., 1921, 479 A.)—D. F. T.

Vulcanisation; Mercaptothiazoles as accelerators of ——. G. Bruni and E. Romani. Atti R. Accad. Lincei, 1922, 31, I., 86—88. (*Cf.* J., 1921, 553 A.)

When added to a mixture of rubber and sulphur containing oxide of zinc, lead, magnesium, calcium, mercury, etc., 1—3% of 5-methyl-2-mercaptothiazole greatly accelerates vulcanisation, which is effected in 5 minutes at 120° C. The cadmium, lead, mercuric, and especially the zinc salts of the thiazole exhibit similar accelerating action.
—T. H. P.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins and similar compounds. IX. Stereoisomeric catechins. II. K. Freudenberg, O. Böhme, and L. Purrmann. Ber., 1922, 55, 1734—1747.

A further step in the elucidation of the constitution of the catechins (*cf.* J., 1921, 520 A, 781 A) has been made through the observation that *r*-catechin is transformed into *r*-epicatechin under conditions which causes the racemisation of *l*-catechin. It follows that catechin must contain two asymmetric carbon atoms, which is possible only if the unlocated hydroxy group replaces the hydrogen of a methylene group. Acacia (Pegu) catechu contains a mixture of *r*- and *l*-catechins and *r*- and *l*-epicatechins. The catechin from Chinese rhubarb is pure *d*-catechin; that from mahogany contains *r*- and *d*-catechins and probably also *d*-epicatechin, but only steamed wood in which the original catechins had suffered alteration was available for the examination; the catechin from *Paullinia cupana* is similar to that from mahogany. (*Cf.* J.C.S., August.)—H. W.

Flavanone; Reduction of ——. K. Freudenberg and L. Orthner. Ber., 1922, 55, 1748—1751.

Flavanol (4-hydroxyflavan), a possible parent substance of catechin (Freudenberg, Böhme and Purrmann, *cf. supra*), has been prepared by the reduction of flavanone with aluminium amalgam in neutral alcoholic solution. It gives a decided reddish-violet coloration with concentrated sulphuric acid; this is much more intense than the yellowish-red shade given by tetramethylcatechin which, however, gradually becomes darker when the mixture is preserved. (*Cf.* J.C.S., August.)—H. W.

Catechin. K. Freudenberg. Ber., 1922, 55, 1938—1942. (*Cf.* Nierenstein, J., 1922, 184 A, 407 A.)

The author maintains his contention that the tannins are condensation products of catechin-like substances. Attempts to prepare catechincarboxylic acid according to Nierenstein's directions were unsuccessful, the catechin appearing to be decomposed completely during the action. Similar observations were made with hydroxycatechin. The catechincarboxylic acid from *Paullinia* tannin is optically active and resolvable; its conversion by loss of carbon dioxide into *d*-catechin (gambier catechin) is therefore inexplicable. Demethylation of tetramethylcatechin cannot be effected by acetic anhydride and acetyl chloride, whilst penta-acetylcatechin cannot be hydrolysed by sulphuric acid to catechin as claimed by Nierenstein. The identity of the methylated reduction product of catechin, m.p. 87°—88° C., with pentamethoxy-$\alpha\gamma$-diphenylpropane has been confirmed; Nierenstein's synthesis of acacatechin is therefore difficult to understand, since his compounds belong to the $\alpha\alpha$-diphenylpropane group.—H. W.

Glue; Action of alum on animal ——. A. Gutbier, E. Sauer, and F. Schelling. Kolloid-Zeits., 1922, 30, 376—395.

Alum strongly increases the viscosity of glue and at higher temperatures, in slightly acid solutions, causes precipitation. The addition of alum to both bone and leather glue immediately reduces the colour. The sensitiveness of glue to alum varies with the different varieties; thus the viscosity of leather glue is increased by very small concentrations of alum, whilst very large concentrations are necessary to give a noteworthy increase of viscosity with bone glue. At higher temperatures, in the case of leather glue, there is a continuous decrease in the viscosity depending on the concentration of the alum and the time during which the two substances have been in contact. Bone glue is much more stable than leather glue to alum and to high temperatures. When glue jellies mixed with alum are dialysed the aluminium is retained quantitatively, but the other constituents of the alum are removed. The precipitates produced during the clarification of glue by alum and phosphoric acid contain both glue and aluminium in varying proportions and are adsorption compounds; they have a considerable surface energy and consequently possess a great clarifying power. The more rapidly the precipitate forms the greater is the clarifying power. After proper clarification the glue contains only small quantities of aluminium, but it contains the whole of the acid added. The clarification of glue is always accompanied by a deterioration, as shown by the decrease in viscosity. This is not due directly to the clarification process but to secondary reactions. The acid added and the prolonged heating bring about hydrolysis which yields substances that are not glue-like. Leather glue is more sensitive than bone glue in this respect.—J. F. S.

Patents.

Tanning materials; Manufacture of new —— and process of tanning therewith. Chem. Fabr. und Asphaltwerke A.-G. E.P. 156,254, 4.1.21. Conv., 1.9.16.

Tanning materials prepared by condensing organic compounds with formaldehyde are neutralised with compounds of aluminium or chromium, or both. —D. W.

Tanning of skins and hides. J. Hell. E.P. 180,758, 1.3.21.

Hides are unhaired and then treated with soluble magnesium salts and soluble carbonic acid salts of other bases in the presence of water, which may be followed by a treatment with other tanning materials.—D. W.

Tanning. T. B. Carmichael and W. H. Ockleston. E.P. 181,067, 24.2.21.

Hides are treated with an acidified green chrome liquor and then with a vegetable tanning liquor, or they are treated with a combined tanning liquor consisting of equal parts of an acidified green chrome liquor of about 20° Bkr. and a vegetable tanning liquor of about 30°—40° Bkr., which may be followed by further treatment in vegetable tan liquors. The acidified green chrome liquor is prepared by adding acetic acid to a commercial chrome tanning liquor.—D. W.

Glue; Process of, and apparatus for, extracting —— from glue-yielding raw materials by means of water. K. Niessen. E.P. 156,645, 6.1.21. Conv., 8.12.19.

The raw material is heated with water under reduced pressure in a series of extractors, which are charged in turn. The water freshly introduced into an extractor passes through all but one of the extractors in series in such an order that the liquor is enriched and concentrated in each by contact with fresher material and by partial evaporation of the water. The water in regular circulation passes from the bottom of one extractor to the top of the next vessel, wherein it is preferably discharged through a sprinkler. Each extractor is provided with automatic valve controlling gear by means of which the passage of liquor through the system is controlled.—J. R.

Casein; Manufacture of plastic material from ——. E. Krause and H. Blücher. E.P. 162,657, 29.4.21. Conv., 3.5.20.

Casein, which may be ground to pass a 2000-mesh sieve, is treated with formaldehyde, dried so as to remove any free formaldehyde, and compressed hot into the desired shape.—D. W.

XVI.—SOILS; FERTILISERS.

Nitrogenous metabolism of the higher plants; Investigations on the ——. II. Distribution of nitrogen in the leaves of the runner bean. A. C. Chibnall. Biochem. J., 1922, **16**, 344—362.

Numerous determinations have been made of the nitrogen content of the leaves of the runner bean, particularly to determine seasonal and diurnal variations and the results of starvation. The results indicate the synthesis of protein from nitric-nitrogen through monoamino-nitrogen, and then the degradation of protein to non-protein nitrogen, followed by translocation from the leaf.—W. O. K.

Fungi; Chemistry of the higher ——. XV. Chemical relations between the higher fungi and their substratum. II. R. Hasenöhrl and J. Zellner. Monatsh., 1922, **43**, 21—41.

The physical and chemical characteristics of the higher fungi resemble closely those of the heterotropic phanerogams (*cf.* Monatsh., 1919, **40**, 311). They contain a considerably higher proportion of water than green plants, and more water than the host on which they are parasitic. The composition of the mineral matter in the fleshy fungi resembles that in phanerogams, potassium and phosphorus being high and calcium low. In some of the more woody or leathery fungi, however, calcium sulphate is exceptionally high. In general the fungi contain a high proportion of soluble salts, which are necessary to maintain the high osmotic pressure required in plants of such high water content. The osmotic pressure in the fungus is shown experimentally to be higher than in the substratum. Attempts to detect cellulose- and lignin-splitting enzymes in a number of fungi were unsuccessful. A specimen of oak on which *Polyporus igniarius* had been parasitic was found to have lost 74% of its weight, the sp. gr. being reduced from 0·740 to 0·191. Its analysis, however, showed little difference in composition from that of healthy oak, except that starch, tannin, and sugar had disappeared. The material of the wood appears, therefore, to be absorbed equally by the fungus. (*Cf.* J.C.S., August.)—E. H. R.

Catalase of seeds. J. de Vilmorin and Cazaubon. Comptes rend., 1922, **175**, 50—51. (*Cf.* Němec and Duchon, J., 1921, 899 A; 1922, 264 A.)

In the case of the seeds of pines and larches the authors find no correlation between the amount of catalase present and the vitality of the seed as shown by its germinative capacity.—W. G.

Patents.

Fertilisers; Manufacture of artificial nitrogenous ——. K. Niedenzu. E.P. 166,887, 9.7.21. Conv., 23.7.20.

A mixture of calcium sulphate and carbonaceous material is heated at 1000°—1300° C., and gases containing nitrogen (producer-gas etc.) are passed through the mixture. Calcium cyanide and cyanamide are formed, and the product is ground to a powder. Halogen compounds, oxides, carbonates, and salts of the alkaline-earth metals containing oxygen may be added as accelerators.—A. G. P.

Refuse; Plant for the aerobic fermentation of —— and the production of manure therefrom. Soc. Anon. Brevetti Beccari. E.P. 175,586, 28.2.21. Conv., 16.2.21.

Putrescible refuse is stacked on the perforated floor of a chamber through which a current of air is drawn. Volatile products are trapped by bubbling the escaping air through water. The period of treatment is 30—35 days.—A. G. P.

Fertiliser; Method of conditioning ——. C. A. Butt. U.S.P. 1,418,618, 6.6.22. Appl., 17.6.21.

Nascent hydrogen is generated in a fertiliser material containing a nitrogen compound capable of reacting with nascent hydrogen to produce ammonia. The ammonia formed combines with any free acid present.

Fertilisers. D. Lo Monaco. E.P. 159,481, 25.2.21. Conv., 26.2.20.

See U.S.P. 1,402,368 of 1922; J., 1922, 151 A. The process is intended more particularly for the treatment of humus.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Inversion of —— in alkaline copper solution. E. Canals. Bull. Soc. Chim., 1922, 31, 583—588.

Results indicate that sucrose is slowly hydrolysed during the estimation of reducing sugars in its presence by means of Fehling's solution. The actual amount of sucrose hydrolysed increases with the concentration of the sucrose, with the time of heating, and with the temperature at which the liquid is kept. It is essential, therefore, to make a blank estimation, and it is advisable to heat by immersion in a water-bath.—W. G.

Sucrose lost in the carbonatation scums of the beet sugar factory; Determination of the ——. H. Claassen. Centr. Zuckerind., 1922, 30, 703.

In factories in which the carbonatation scums are not dried but are washed into a screw conveyor and pumped away to waste, the loss of sugar may be determined by taking an average sample from the mixing tank placed before the pump, calculating the weight from the volume and density, and determining the sucrose in a portion in the usual manner. The results given by this method, owing to the greater accuracy in sampling which it permits, are nearer the truth than those found by the procedure generally followed, in which the weight is found directly by weighing and the sugar determined in a portion abstracted from the cakes by means of a trier.—J. P. O.

Sucrose; Spectral study of the triboluminescence of ——. H. Longchambon. Comptes rend., 1922, 174, 1633—1634.

The spectrum of triboluminescence of sucrose shows almost all the constituents of the second positive band spectrum of nitrogen and no others. The triboluminescence of sugar is, therefore, due to a discharge in the air between two solid particles which have been suddenly separated and are electrically charged.—W. G.

Artificial honey; Determination of the dry matter in —— by means of the refractometer. F. Auerbach and G. Borres. Z. Unters. Nahr. Genussm., 1922, 43, 297—311.

The Abbe refractometer was used. The artificial honey was warmed until all crystals had melted and thoroughly mixed before drops were removed for testing. Preliminary experiments carried out to determine the variation of refractive index with temperature gave 0·00025 as the mean fall per degree rise in temperature between 20° and 50° C. Readings were taken after the temperature had remained constant for 5 mins. in the neighbourhood of 40° C. and corrected to that temperature. The results obtained for a large number of samples were compared with the percentage of dry matter as obtained by density determinations. The refractive index increases as a linear function of the percentage of dry matter. The maximum variation in the percentage as given by the refractometer as compared with that given by density determinations is $\pm 0·2\%$, except for artificial honeys prepared with starch syrup, where the variation reached $0·3\%$. Pure starch syrups showed variations up to $2·36\%$. —H. C. R.

Adsorption in solution and at interfaces of sugars, dextrin, starch, gum arabic, and egg albumin; Quantitative study of the —— and the mechanism of their action as emulsifying agents. G. L. Clark and W. A. Mann. J. Biol. Chem., 1922, 52, 157—182.

Measurements were made of the surface tension and viscosity of solutions of the above substances for a large number of concentrations both with and without the addition of electrolytes. The interfacial tension between each solution and benzene was also measured, and the efficiency of the emulsifying agent with respect to both benzene and kerosene estimated. The factors of predominating importance in an emulsifying agent appear to be viscosity and ability to lower interfacial tension. In the case of sugar, viscosity is the more important, whilst with egg albumin, which gave the best emulsions, film formation is of primary importance. Two types of agglomeration are distinguished, namely, that accompanied by an increase in viscosity, in which coalescence of the particles is accompanied by enclosure of water, and that producing a decrease in viscosity, in which there is a decrease both in surface and amount of bound water. Dextrin and starch, considered separately, provide examples of the former type. When these substances are considered in relation to one another, however, it is found that the viscosity curves run parallel, thus resembling the viscosity curves of sulphur sols of different degrees of dispersion (Z. physik. Chem., 1912, 80, 709). This is considered to be evidence that starch and dextrin differ merely in the degree of agglomeration (second type) of the particles, and thus to furnish experimental proof of the view put forward by Herzfeld and Klinger (J., 1921, 784 A).—E. S.

Inulin. Constitution of polysaccharides. IV. J. C. Irvine, E. S. Steele and M. I. Shannon. Chem. Soc. Trans., 1922, 121, 1060—1078.

The formation of dimethylinulin as the main product of the methylation of inulin with methyl sulphate and sodium hydroxide was confirmed. The varying solubility in ether of the compound from different preparations is ascribed to partial depolymerisation. The physical properties of trimethylinulin also vary in marked degree according to the experimental procedure adopted in preparing the compound, the physical state varying from an amorphous solid to an extremely viscous syrup, the latter being dextro- and the former lævo-rotatory.

All forms, however, have the same composition and on hydrolysis give the same form of trimethyl-γ-fructose, the lævo-varieties only undergoing a change of sign during hydrolysis. The occurrence of these varieties of trimethylinulin can only be ascribed to variations in molecular magnitude, the cause of which it is at present impossible definitely to determine. Dimethylinulin, which has always been obtained as a lævo-rotatory compound, shows a change of sign on hydrolysis, giving *d*-dimethyl-γ-fructose, which is valuable confirmatory evidence of the form of fructose of which inulin is a derivative.—G. F. M.

Digestibility of starches. Langworthy and Deuel, jun. *See* XIXA.

PATENTS.

Syrups and molasses in storage; Preservation of ——. W. L. Owen, Assr. to Penick and Ford, Ltd. U.S.P. 1,418,457, 6.6.22. Appl., 31.7.19.

THE syrup or molasses is subjected to carbon dioxide under pressure in suitable reservoirs in order substantially to displace the surrounding and entrained air, and is then stored in an atmosphere of carbon dioxide under a pressure of at least 45 lb. per sq. in.—J. P. O.

Starch and starchy matter and sulphuric acid; Manufacture of compounds or mixtures of —— [*for use in the manufacture of viscose silk, etc.*]. Courtaulds, Ltd., and (A) W. H. Stokes, (B) J. A. Lloyd. E.P. (A) 181,197, (B) 181,198, 23.4.21.

(A) HOMOGENEOUS mixtures of starch and 60% sulphuric acid are made by mixing finely-divided starch or starchy material with water, or preferably dilute sulphuric acid, and adding rapidly, with stirring and cooling, to the paste so obtained sufficient concentrated acid to bring the mixture to the desired concentration: *e.g.*, 14 pts. of starch is made into a paste with 15 pts. of 28% sulphuric acid at about 28°—30° C.; 14 pts. of 77% sulphuric acid is then added rapidly, with continuous stirring and cooling, until after a few hours a clear, homogeneous liquid is obtained, which may be used in the preparation of setting baths for viscose etc. (B) Starch or starchy material, *e.g.*, ground rice or tapioca, not necessarily in a finely-divided state, is added in successive small quantities to 50—65% sulphuric acid at temperatures of 35°—75° C. (the higher the temperature the darker will be the colour of the resulting liquid): *e.g.*, 56 pts of maize starch is added over a period of about 3½ hrs. to 116 pts. of 52% sulphuric acid, maintained at 40° C. The liquid is stirred for another 2 hrs., keeping the temperature at 40° C., when a light-coloured, mobile liquid is obtained.—D. J. N.

Starch products; Method of making soluble ——. A. W. H. Lenders and H. F. Bauer, Assrs. to Penick and Ford, Ltd. U.S.P. 1,418,311, 6.6.22. Appl., 2.7.17.

AN aqueous solution of modified or thin boiling starch, made by the usual process of acid hydrolysis, is subjected without the addition of any reagent to a temperature which instantaneously evaporates the water and further modifies the starch.—J. P. O.

Filter for sugar liquors. E.P. 180,935. *See* I.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Nitrogen nutrition of ——. F. K. Swoboda. J. Biol. Chem., 1922, **52**, 91—109.

THE effect of various substances on the nitrogen nutrition of yeast was studied, the special feature of the experiments being the addition to the synthetic media employed of a constant quantity of growth-promoting vitamin ("bios"). In media containing asparagine, succinamide, succinimide, or aspartic acid, the growth is better in the presence than in the absence of ammonium sulphate. Of the nitrogen contained in asparagine, the α-amino group appears to stimulate nitrogen assimilation; the amide group, however, in the presence of ammonium sulphate, also stimulates cell reproduction. The nutrient value of edestin is increased by mild acid hydrolysis, but is decreased by continued acid hydrolysis and by alkaline hydrolysis. In the latter case subsequent acid hydrolysis again improves the nutrient value. The effect of various amino-acids, both in the presence and absence of hydrolysed edestin, was also studied.—E. S.

Wines; [Detection of] dépiquage of [addition of a neutralising agent to] sour ——. L. Ferré. Ann. Falsif., 1922, **15**, 139—146.

FOR the detection of the addition to sour wines of a substance capable of improving their taste, the author recommends the estimation of the free and combined volatile acids by the following procedure: 10 c.c. of the wine is extracted with three successive 10 c.c. portions of ether. The ether extracts the free volatile acids together with a certain amount of the free fixed acids. The ether is distilled off at a low temperature, and the volatile acids in the residue are estimated by Mathieu's method of successive distillations. The wine left after the extraction is used for the estimation of the combined volatile acids by a similar method after acidification with 0·5 c.c. of sulphuric acid. In the case of a wine containing a considerable amount of free tartaric acid it is almost impossible to discover the addition of a neutralising agent, unless some of the untreated wine is available for comparison. In the case of a wine containing little or no free tartaric acid, however, it is possible not only to detect the addition of a neutralising agent, but also to ascertain the nature of the substance added. —W. G.

Yeast; Flocculation of ——. H. Lüers and K. Geys. Kolloid-Zeits., 1922, **30**, 372—376.

YEAST is normally positively charged or amphoteric, but in the process of fermentation a negative charge appears when vigorous budding sets in. Towards the end of the fermentation the charge again becomes positive at the same time as flocculation commences. These changes are very indistinct with powdery yeast. The change from yeast exhibiting a good "break" to powdery yeast often observed in practice is due to hunger, degradation of albumin, and reduction of the hydrogen ion concentration.—J. F. S.

Fat; Conditions influencing the formation of —— *by the yeast cell.* I. S. Maclean. Biochem. J., 1922, **16**, 370—379.

ETHER extracts considerably more fat from yeast if the latter be first boiled with *N*/1 hydrochloric acid for two hours. This is because a large part of the fat is in some form of combination in the plasma of the cell. Yeast grown under unfavourable conditions shows a large increase in fat content (up to 9%). Aeration, and a non-nitrogenous medium rich in carbohydrate, likewise cause an increased fat content, the increase being in the combined fat.—W. O. K.

Amylase of Aspergillus niger; Influence of hydrogen ion concentration on the action of ——. G. L. Funke. Proc. K. Akad. Wetensch., 1922, **25**, 6—8.

THE maximum hydrolytic action of the amylase from *Aspergillus niger* is observed at a hydrogen ion concentration p_H 3·5—5·5, and from this it follows that the enzyme is to be regarded as an ampholyte of which $k = 6·3 \times 10^{-7}$ and $k_b = 2·884 \times 10^{-13}$. Malt amylase has the values $k_a = 6·3 \times 10^{-7}$ and $k_b = 5·76 \times 10^{-11}$, where k_a and k_b are the dissociation constants of the acid and base respectively. (*Cf.* J.C.S., Aug.)—J. F. S.

Cider-making; Microbiology of ——. B. T. P. Barker. J. Inst. Brew., 1922, 28, 517—534.

The freshly expressed apple juice used for cider-making is invariably charged not only with a variety of naturally occurring wild yeasts and torulæ, but also with a heterogeneous collection of undesirable fungi and bacteria. The three possible general methods of fermenting this crude juice are spontaneous or natural fermentation (still the most important industrial process), by dominant fermentation, to attain which the addition of a culture of selected yeast to freshly expressed juice is necessary, and by pure fermentation, which involves preliminary sterilisation, followed by the addition of a pure yeast culture. For pure fermentations the juice may be either pasteurised by heating to 140°—160° F. (60°—71° C.) or sterilised by chemical or physical means, and then fermented. Sulphur dioxide, ozone, and ultra-violet rays have been suggested for sterilising the juice but have not met with any great practical success. Another reagent which offers more promise of success (although experiments are only in the preliminary stage) is formaldehyde. There is naturally present in apple juice a substance or a group of related substances which slowly combine with formaldehyde in the cold to produce an insoluble compound, so that sterilisation of the juice can be combined with the automatic removal of the excess formaldehyde. Pasteurisation sometimes affects the flavour of the cider. During cider making there is a continuous struggle in progress between the yeast capable of producing a sound type of alcoholic fermentation and undesirable yeasts and bacteria. Provided there is sufficient good yeast active to keep the liquor nearly saturated with carbon dioxide, the risk of serious deterioration from bacterial development is not great. Other factors, however, besides the presence of carbon dioxide are involved in the preservative action, so far at least as some of the bacterial disorders are concerned (*e.g.*, cider sickness). This disorder is characterised by the sudden decomposition of the residual sugar, alcohol being formed in addition to various aldehydes, including formaldehyde.—J. R.

Alcohol still; Plate efficiency of a continuous ——. C. S. Robinson. J. Ind. Eng. Chem., 1922, 14, 480—481.

Three tests were carried out on a modern Barbet plant using mixtures of ethyl alcohol and water, with a view to determine the plate efficiency of the plant. Observations were made of the alcohol fed, water fed, cooling water used, water in distillate, and temperature rise in the various condensers. From the data the plate efficiencies were calculated, using the formulæ given by W. K. Lewis (*cf.* p. 573 a). When the reflux ratio (ratio of reflux to product) was 4·06 a plate efficiency of 40% was found; with a reflux ratio of 3·04 the plate efficiency was 24%, and a plate efficiency of 56% was obtained when the reflux ratio was 2·75. In each case it was assumed that the alcohol present in the waste liquor was 0·0001. Another test by another experimenter on the same plant gave a plate efficiency of 70%, and, applying this result to the first of the above tests, it is found that waste should be 0·000002 mol. fraction of alcohol instead of 0·0001 as assumed. It is pointed out that for an accurate determination of plate efficiency it would be necessary to obtain samples of liquid containing a measurable amount of alcohol.
—S. G. U.

Pressed yeast; Regulation of the nutrient liquid for the manufacture of —— *on a chemical basis.* F. Wendel. Z. Spiritusind., 1922, 45, 160, 166—167, 171—172.

The food requirements of yeast made by the aeration process as regards sugar, nitrogen, and phosphoric acid are considered, and the proportions of different cereals and inorganic materials which must be used to satisfy these requirements and yield yeast of good baking and keeping qualities estimated.—T. H. P.

Polypeptidases, carbohydrases, and esterases; Influence of substances obtained from yeast cells and organs on the time course of the fission of substrates by ——. E. Abderhalden and E. Wertheimer. Fermentforsch., 1922, 6, 1—26.

Substances extracted from yeast in various ways, and also certain optones, accelerate the fission of dipeptides by pancreas extract, but diastatic action is not appreciably affected by this means. The action of sucrase (invertase) is retarded by the substances extracted from yeast by treatment with alcohol. (*Cf.* J.C.S., Aug.)—T. H. P.

Bacteria; Culture of —— *on media with a basis of pyruvic acid. Degradation of pyruvic acid.* R. Cambier and E. Aubel. Comptes rend., 1922, 175, 71—73.

The authors have found it possible to grow *B. pyocyaneus*, *B. fluorescens*, and *B. coli* on a mineral medium containing sodium pyruvate as its sole source of carbon. Among the products of degradation of the pyruvic acid they have identified acetic, glycollic, and lactic acids.—W. G.

Trypsin. Kai. *See* XXIII.

Patents.

Yeast; Process of drying pressed ——. E. Klein. E.P. 175,623, 10.2.22. Conv., 15.2.21.

Yeast is dried by air currents until the water content is reduced to 50—60%. Starch or flour is then added to bring down the percentage of water to 30%, followed by substances protecting the fermentative activity of the yeast, *e.g.*, potassium phosphate, sugar, etc. Common salt is added during the drying process to facilitate the removal of water from the yeast cells.—A. G. P.

Yeast; Method for treating and preparing ——. C. A. Jensen. From R. L. Corby. E.P. (a) 181,076 and (b) 181,293, 28.2.21.

(a) Pressed yeast is frozen at about –4° C., to remove water from the cells, and then allowed to regain normal temperature. Corn (maize) meal is added and/or a suitable oil, and the whole thoroughly mixed. A small amount of water, *e.g.*, 35%, is added, and the whole desiccated, *e.g.*, in a current of air. (b) Previous to drying, yeast is treated with a solution of sugar (40—100 lb.), ammonium tartrate (1—3 lb.), calcium phosphate (½—2 lb.), and lactic acid (½ lb.), in water (200 gallons). This quantity is suitable for treating 100 lb. of yeast.—A. G. P.

Filter for wines. E.P. 180,935. *See* I.

XIXa.—FOODS.

Milk as a source of water-soluble vitamin. III. T. B. Osborne and L. B. Mendel. Biochem. J., 1922, 16, 363—367.

Cow's milk shows great variations in its content of vitamin B, apparently scarcely to be accounted for by differences in the diet of the cows, and in no case has a sample been found with a content

of vitamin B approaching that found by Hopkins in his original experiments. Human milk is not essentially richer than cow's milk in this vitamin.
—W. O. K.

Meats; Pickling of —— in brines containing potassium nitrate and sodium nitrite. L. Pollak. Z. angew. Chem., 1922, **35**, 229—232.

WHEN potassium nitrate is used in the pickling solution the process proceeds irregularly, and considerable quantities of nitrite are formed, whilst when sodium nitrite is added to the solution the pickling process progresses regularly, the nitrite content of the solution decreases gradually, and only small quantities are present at the end of the operation. Meat pickled with nitrite never contained more than 15 mg. of sodium nitrite per 100 g., but this quantity was usually exceeded when nitrate had been used.—W. P. S.

Meat; Use of potassium nitrate and sodium nitrite in the pickling of ——. F. Auerbach and G. Riess. Z. angew. Chem., 1922, **35**, 232—233.

THE authors consider that the formation of nitrite when nitrate is used in pickling meat, as recorded by Pollak (preceding abstract), is due to the temperature having been too high during Pollak's experiments. They find that at 4° C. the quantity of nitrite formed is very small. Further, when nitrite is employed, the quantity found in the finished meat varies proportionately with the amount in the brine solution.—W. P. S.

Lupin seeds; Removal of bitter substances from ——. [Determination of the efficiency of the treatment]. E. Beckmann and F. Lehmann. Chem.-Zeit., 1922, **46**, 473—474.

FIVE g. of the crushed seeds is digested for 20 mins. with 50 c.c. of water at 60° C.; the liquid is filtered, the filtrate cooled, and a small quantity treated with a few drops of iodine solution. If the seeds are free from bitter substances the mixture remains perfectly clear. The aqueous extract from untreated lupin seeds, or that from seeds from which the bitter substances have not been removed completely, gives a precipitate or turbidity when tested with iodine solution.—W. P. S.

Fat-soluble factor; Relation of —— to rickets and growth in pigs. II. J. Golding, S. S. Zilva, J. C. Drummond, and K. H. Coward. Biochem. J., 1922, **16**, 394—402.

PIGS fed on a diet deficient in vitamin A, or in calcium, or in both, show no definite picture of rickets, though they exhibit signs of diminished vitality.—W. O. K.

Antiscorbutic vitamin. I. A study of its solubility from desiccated orange juice. E. B. Hart, H. Steenbock, and S. Lepkovsky. J. Biol. Chem., 1922, **52**, 241—250.

THE antiscorbutic vitamin is soluble in 80%, 95%, and absolute alcohol, and also in methyl alcohol, but is insoluble in butyl alcohol, benzene, petroleum ether, acetone, ether, chloroform, and ethyl acetate. Its solubility is greater in dilute than in absolute alcohol.—E. S.

Muscle; Effect of cold storage on the carnosine content of ——. W. M. Clifford. Biochem. J., 1922, **16**, 341—343.

USING the colorimetric method previously described (J., 1921, 672 A), it has been found that the carnosine content of meat decreases during cold storage.
—W. O. K.

Coconut oil meal; Relative growth-promoting value of the protein of —— and of combinations of it with protein from various other feeding stuffs. L. A. Maynard and F. M. Fronda. Cornell Univ. Agr. Exp. Stat. Mem. 50, Dec., 1921, 621—633.

WHITE rats were fed on a diet, containing coconut oil meal, so arranged that the total amount of protein present was insufficient for normal growth, even when the diet was fed *ad libitum*. Comparison was made of various diets on the basis of gain per gram of protein eaten. The protein of coconut oil meal was superior to that of corn (maize) meal. Rice bran and wheat middlings were found to be efficient supplements to coconut oil meal. Results were not very satisfactory when coconut oil meal was supplemented with alfalfa (lucerne), and the addition of kaffir corn resulted in no improvement in the quality of the protein.
—A. G. P.

Volatile fatty acids [in silage]; Estimation of ——. G. Wiegner and J. Magasanik. Mitt. Geb. Lebensmittelunters. Hyg., 1919, **10**, 156—174. Biedermann's Zentr., 1922, **51**, 140—145.

FROM an equation showing the relationship between the relative amounts of water and acid in a distillation residue at the beginning and end of a distillation interval, a method is developed for the estimation of volatile fatty acids in aqueous extracts of silage. (*Cf.* J.C.S., July.)—G. W. R.

Starches; Digestibility of raw rice, arrowroot, canna, cassava, taro, tree-fern, and potato ——. C. F. Langworthy and H. J. Deuel, jun. J. Biol. Chem., 1922, **52**, 251—261.

THE digestibility of raw starches eaten, in some cases, in amounts as large as 250 g. a day was studied. Cassava, rice, and taro root starches were digested completely, tree-fern and arrowroot (*Maranta arundinacea*) starches nearly completely, and commercial arrowroot (*Zamia floridana*), potato, and canna starches incompletely. There appears to be a direct relationship between the size of the starch granules and its digestibility, the smaller granules being more readily digested.

Egg albumin, sugars, etc., as emulsifying agents. Clark and Mann. *See* XVII.

Trypsin. Kai. *See* XXIII.

PATENTS.

Dehydrators for fruits, vegetables and other foods. R. Rea. E.P. 180,806, 21.3.21.

THE material is conveyed in a series of trays on rollers through a drying tunnel, through which hot air is drawn by means of fans. Temperature and air supply are controlled by means of dampers. Trays are introduced at the cool end of the tunnel and withdrawn at the hot end. If necessary a pan of sulphur is placed at the air inlet to minimise oxidation and blackening of the material during drying.—A. G. P.

Fats; Treatment of edible ——. W. Douglas and Sons, Ltd., and J. S. Nicol. E.P. 181,077, 1.3.21.

THE colour, grain, and texture of lard or lard compounds are improved by forcing the fat in a tortuous path through a series of perforations and grooves in and spaces between two or more concentric hollow cylinders from the exterior of the outermost cylinder to the interior of the innermost cylinder, or *vice versâ*. One of the cylinders may be rotated to increase the rubbing effect on the fat. The cylinders may be provided with circumferential grooves, with which some of the perforations communicate, and the edges of some of the grooves may be serrated. The apparatus is provided with a by-pass controlled by a cock in such a way that when the fat is not being collected it is returned to the pump from the casing enclosing the cylinders without passing through the latter.—H. C. R.

*Bread; **Manufacture of** ——.* W. Watson, D. W. Kent-Jones, and Woodlands, Ltd. E.P. 181,397, 3.5.20.

A small quantity of a harmless hypochlorite or "chloro-hypochlorite" such as the sodium salt (*e.g.*, 0·005 to 0·01 pt. per 100 pts. of flour) or the calcium salt (*e.g.*, 0·045 pt. of bleaching powder per 100 pts. of flour) is incorporated with flour, and the treated flour made into a dough, which is baked. —J. R.

Yeast. E.P. 175,623, 181,076, and 181,293. *See* XVIII.

XIXb.—WATER PURIFICATION; SANITATION.

Equilibrium of bases in permutite. Günther-Schulze. *See* VII.

Patents.

Filtration of liquids. [*Sand filters.*] B. Bramwell. E.P. 181,044, 6.1.21.

The sand is removed layer by layer from a foul filter bed, cleansed, and re-deposited in a neighbouring bed by means of a suction apparatus which automatically travels in both horizontal directions. A reverse current wash may be applied to the foul bed while this is being discharged.—B. M. V.

Garbage reducer and distillator. P. L. Goodman. U.S.P. 1,419,135, 13.6.22. Appl., 6.11.20.

Refuse is distilled in a series of detachable retorts, having removable dome-shaped heads, from which the distillate is carried away to condensers. The carbonaceous residues can be used as fuel in the furnace.—A. G. P.

Metaldehyde; Burner for burning ——. Elektrizitätswerk Lonza, and A. Busch. E.P. 181,512, 23.3.21.

Metaldehyde moulded into the form of a candle is placed in a vertical cylindrical container and fed upwards as it burns by means of a spring under compression at the bottom of the holder. A guard is placed over the top of the material to prevent its ejection from the burner, and the top of the holder is manufactured from non-conducting material. —A. G.

Trade effluent and the like; Apparatus for separating the solid matter from ——. T. Waite and T. Boldy. E.P. 181,071, 26.2.21.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Toads; Poisonous substance of ——. H. Wieland and R. Alles. Ber., 1922, **55**, 1789—1798.

Further attempts to isolate the poisonous material from the skin of the toad have led to an unexpected result, since a more careful repetition of methods that were previously successful (Wieland and Weil, Ber., 1913, **46**, 3315) did not lead to the isolation of bufotalin. It appears that this is not present as such but is a product of the decomposition of the actual poison, bufotoxin, $C_{46}H_{62}O_{11}N_4$, m.p. 204°—205° C. The isolation of the latter from the extract of the skins and the secretions of the glands is described in detail. Bufotoxin is hydrolysed by dilute acids to bufotalein, $C_{24}H_{30}O_3$, and suberylarginine. (*Cf.* J.C.S., August.)—H. W.

Secale cornutum and so-called ergot substitutes. A. Tschirch. Schweiz. Apoth. Zeit., 1922, **60**, 1—6. Chem. Zentr., 1922, **93**, I., 1341.

The action of ergot substitutes, such as *Capsella*, is attributable to protein decomposition products. Since proteinogenous amines can be expected particularly in the extracts of fungi which are rich in protein, it is very probable that *Capsella* which has been attacked by the fungus *Cyclopus candidus* would be particularly active. Until, however, the conditions for the inception and course of the protein decomposition can be controlled, the extracts of all ergot substitutes are at best uncertain in their action and sometimes quite inert. The colouring matters of *Secale cornutum*, scleroxanthin and scelerythrin, have spectroscopically a certain relationship with red bacterial colouring matters, and in addition a third colouring matter is present which after extraction of the surface layer with alcoholic hydrogen chloride, alcoholic ammonia, and alcoholic sodium hydroxide is dissolved by concentrated sulphuric acid to a red solution, which shows a broad, faint band between $\lambda=540$ and $\lambda=570$. The solution in alcohol is yellow and shows only end absorption.—G. F. M.

Capsularin, a glucoside from jute leaf. H. Saha and K. N. Choudhury. Chem. Soc. Trans., 1922, 121, 1044—1046.

Matured leaves of *Corchorus capsularis* were extracted with boiling water, the extract clarified with lead acetate and concentrated to a small bulk. The glucoside was precipitated with tannic acid, and after liberation with barium hydroxide and recrystallisation it formed needle-shaped crystals, m.p. 175°—176° C. This glucoside, capsularin, is not identical with corchorin isolated by Kobert from the seeds of the same plant. It has the molecular formula $C_{22}H_{36}O_8$, $[\alpha]_D = -23{\cdot}6°$, and its penta-acetyl derivative melts at 194° C. It is very bitter to the taste, develops a red coloration with sulphuric acid, and on hydrolysis gives a mixture of *d*- and *l*-glucose. The second product of hydrolysis forms small needles, m.p. 185°, and gives with acetic anhydride, chloroform, and sulphuric acid a violet colour changing to green, a reaction characteristic of the alcohols of the $C_nH_{2n-6}O_4$ series.—G. F. M.

Castelin, a new glucoside from Castela Nicholsoni. L. P. Bosman. Chem. Soc. Trans., 1922, **121**, 969—972.

The active principle of *Castela Nicholsoni* (N.O. *Simarubaceæ*) is a hygroscopic, optically active glucoside, castelin, $C_{15}H_{22}O_8.3H_2O$, associated with a bitter principle, castelmarin. Castelin, white needles from water, m.p. 205° C. (anhydrous), $[\alpha]_D = +62{\cdot}9$ in aqueous solution, is soluble in water (1 in 85 pts. at room temperature, 1 in 25 pts. at 100° C.), ethyl alcohol, and cold concentrated hydrochloric acid, and gives a violet coloration with concentrated sulphuric acid. Castelagenin, $C_9H_{12}O_3$, its product of hydrolysis, m.p. 240°—241° C., $[\alpha]_D = +59°$ C., gives no coloration with sulphuric acid, and is lactonic in nature. The osazone of the sugar constituent is identical in appearance with glucosazone, and melts at 207°—209° C.—P. V. M.

Glucosides; New ——. R. de Fazi. Gazz. Chim. Ital., 1922, 52, I., 429—431.

The glucosides of 2-hydroxybenzylideneindene, 2-hydroxybenzylidenefluorene, and 2-hydroxybenzylideneacenaphthenone, prepared by condensation of helicin with indene, fluorene, and acenaphthenone, respectively, in presence of sodium ethoxide, are described. (*Cf.* J.C.S., Aug.)—T. H. P.

Amyrols; Isomeric ——. V. Paolini. Atti R. Accad. Lincei, 1922, 31, I., 374—377. (*Cf.* von Soden, J., 1900, 464; 1901, 64.)

Amyrol, the alcoholic terpene compound occurring in the essential oil of *Amyris balsamifera,* may be separated into *d*-amyrol, b.p. 302°, sp. gr. 0·982 at 15° C., $[\alpha]_D = +74°16'$, and *l*-amyrol, b.p. 295°, sp. gr. 0·980 at 15° C., $[\alpha]_D = -1°59'$. Both compounds are dense, oily liquids of unpleasant odour. (*Cf.* J.C.S., Aug.)—T. H. P.

Sulphonimides of the naphthoic acids; Isomeric —— : a contribution to the theory of dulcigenic groups. H. P. Kaufmann and H. Zobel. Ber., 1922, 55, 1499—1508.

The preparation of 2-naphthoic acid 1-sulphonimide, 1-naphthoic acid 2-sulphonimide, 2-naphthoic acid 3-sulphonimide and 1-naphthoic acid 8-sulphonimide is described. The constitution of these compounds is closely analagous to that of saccharin from which they differ by having the benzene nucleus of the latter replaced by naphthalene. In their chemical characteristics they are very nearly allied to saccharin, whereas they are distinguished physiologically by having a pronouncedly bitter taste, which is still more marked in their freely soluble sodium salts.—H. W.

Constitution and pharmacological action; Relationship between —— in the case of benzoic and tropic esters of alkylamines. J. von Braun, O. Braunsdorf, and K. Räth. Ber., 1922, 55, 1666—1680.

A series of alkylamines of the types,

$$R_2N\cdot[CH_2]_2\cdot OH,\ R_2N\cdot[CH_2]_3\cdot OH,$$
$$R{:}N\cdot[CH_2]_2\cdot OH \text{ and } R{:}N\cdot[CH_2]_3\cdot OH$$

have been prepared and the hydrogen atom of the hydroxy group has been replaced by the benzoyl and tropoyl residues. The benzoates of the γ-alkylamines are generally more active physiologically than those of the β-hydroxy bases, whereas the reverse is the case with the tropates. With regard to the influence of the number of the members of the nitrogen ring, it is shown that the six-membered ring is the most active both with respect to the anæsthetising action of the benzoates and the mydriatic and cardiac action of the tropates. The linking of carbon chains to the nitrogen ring increases the physiological action but only to a remarkably slight degree. The union of an aromatic ring with the monocyclic nitrogen ring diminishes the physiological action but an exact comparison is difficult in these cases and the effect is not very marked. (*Cf.* J.C.S., August.)—H. W.

Cholesterol; Some new colour reactions of ——. L. Kahlenberg. J. Biol. Chem., 1922, 52, 217—225.

Cholesterol dissolves in arsenic trichloride to a pink solution changing to cherry-red; isocholesterol yields a cobalt-blue solution changing through violet, purple, and dark red to dark green; phytosterol, however, dissolves to a colourless solution. The colours are discharged by the addition of solvents such as benzene, toluene, and chloroform. The colour reactions are also obtained with hot solutions of arsenious oxide in concentrated hydrochloric acid, but are not so permanent as with the anhydrous chloride. Coloured solutions, which are not, however, sufficiently characteristic to be used for distinguishing between the sterols, are also obtained with certain other acid chlorides. —E. S.

Proteins; The natural ——. *I. Behaviour of chlorine dioxide towards organic substances.* E. Schmidt and K. Braunsdorf. Ber., 1922, 55, 1529—1534.

The behaviour of substances closely allied to the natural proteins towards chlorine dioxide has been investigated by the method described previously (J., 1921, 764 A), except that the final addition of reagents to the solution under investigation is made in the sequence, 2*N* sulphuric acid (3 c.c.), 2*N* aqueous potassium iodide solution (1·5 c.c.), water (2—3 c.c.). The substances are considered as stable towards the reagent when the chlorine dioxide content of the solution is not diminished by more than 2% after periods of 24, 48, or 72 hours in the different instances. The following are stable:—Amino-acids and their derivatives (urethane, glycine, glycine hydrochloride, ethyl aminoacetate hydrochloride, aminoacetonitrile sulphate, glycineamide hydrochloride, phenylaminoacetic acid, hippuric acid, betaine, creatine, alanine, phenylalanine, valine, leucine, aspartic acid, asparagine, glutamic acid, serine, hydroxyproline, taurine, glycylglycine hydrochloride, leucylglycine, triglycine); amines and their derivatives (tetra- and penta-methylenediamine hydrochlorides, α-aminopropane-β-ol oxalate, guanidine hydrochloride, tetramethylammonium chloride, choline hydrochloride); amides and their derivatives (acetamide, chloroacetamide, propionamide, phenylacetamide, δ-dimethyloxamide, urea, biuret, hydantoin); imides (glutarimide, phthalimide); polyhydroxy alcohols (glycol, glycerol, mannitol, carbohydrates, inositol); mono- and poly-basic acids (acetic, chloroacetic, stearic, benzoic, oxalic, and adipic acids, trilaurin, tristearin, α-crotonic acid, maleic acid and its anhydride, fumaric acid); hydroxyacids, esters (ethyl lactate, tartaric, citric, and quinic acids); nitriles (acetonitrile, benzonitrile, ethylene dicyanide); cyclic compounds (benzene, naphthalene, cyclohexane, pyridine sulphate, quinoline hydrochloride, piperidine hydrochloride, β-nitroanethol). The following substances are attacked by chlorine dioxide:—Amino-acids and their derivatives (tyrosine, N-benzoyltyrosine, 3.4-dihydroxyphenylalanine, tryptophan, histidine hydrochloride, cystine); mono- and poly-hydroxyphenols; unsaturated carbon compounds (cyclohexene, allyl alcohol, anethol, cinnamyl alcohol, cinnamaldehyde, oleic acid, triolein, uric acid, furfural, indole, β-methylindole); carbon sulphur compounds (mercaptans, dialkyl disulphides, compounds such as thiourea). Histologically, a solution of chlorine dioxide in acetic acid is very useful for the removal of stains due to melanins from tissues, without in the least affecting their anatomical features.—H. W.

Neoarsphenamine [neosalvarsan]; Estimation of sulphate in ——. E. Elvove. J. Ind. Eng. Chem., 1922, 14, 624—626.

About 200 c.c. of distilled water is boiled down to about 150 c.c. and to the hot solution 0·2 g. of the sample is added, followed immediately by 10 c.c. of *N*/1 hydrochloric acid, or sufficient completely to dissolve the precipitate which first forms. The liquid is then boiled down to 50 c.c., diluted with water to 150 c.c., heated to boiling, and the sulphate precipitated by the addition of 15 c.c. of

0·05 molar barium chloride. The results obtained by this direct method are lower than the amounts found by the method of Raiziss and Falkov (J., 1921, 320 A), but it is considered that the latter are too high owing to oxidation occurring during the precipitation and filtration of the formaldehyde-sulphoxylic acid derivative which is involved in this method. The amounts of sulphate found calculated as Na_2SO_4 varied, in 34 samples from 10 different manufacturers, from 1·4 to 17·6%, averaging 1·76 to 5·82% for each series.—G. F. M.

Alcohol for use in the preparation of perfumes and cosmetics; Substances for denaturing ——. Reichsmonopolamt für Branntwein. Chem.-Zeit., 1922, **46**, 476.

The use of the following substances is allowed for the purpose of denaturing alcohol: diethyl phthalate, 2 l., turpentine oil, 1 l., or thymol, 1 kg., per 100 l. of alcohol.—W. P. S.

Allyl alcohol. Conversion to glyceryl chloro- and bromo-hydrins. J. Read and E. Hurst. Chem. Soc. Trans., 1922, **121**, 989—999.

GLYCERYL-β-MONOHALOGENO- and β-dihalogenohydrins, the former in predominating amount, are formed by the action of cold chlorine water and bromine water respectively on allyl alcohol. The monobromo-derivative is obtained in 60% yield by passing a current of air laden with bromine vapour into a mechanically stirred solution of allyl alcohol in water, neutralising the product with sodium carbonate, saturating with anhydrous sodium sulphate, and extracting with ether. The β-dibromohydrin is isolated simultaneously, representing about 44% of the final product, and is only separated by prolonged fractional distillation. A preferential formation of dibromohydrin amounting to 72·9% of a mixture representing 88% of total bromhydrin obtainable, is produced by treating allyl alcohol in its own weight of water with liquid bromine under the same conditions. The action between allyl alcohol and chlorine water is much more vigorous and hence more difficult to control. Only 11·2 and 10·8% of mono- and dichlorohydrins respectively can be isolated.—P. V. M.

Tertiary ethylenic alcohols (linalool type); Conversion of —— into primary ethylenic alcohols (geraniol type). R. Locquin and S. Wouseng. Comptes rend., 1922, **174**, 1711—1713.

DIALKYLVINYLCARBINOLS of the general type, $HO.CRR'.CH{:}CH_2$, readily undergo isomerisation when heated with glacial acetic acid at 100°—115° C. for 15 hours, giving $\gamma\gamma$-dialkylallyl alcohols of the type, $CRR'{:}CH.CH_2OH$, which by controlled oxidation give the corresponding $\beta\beta$-dialkylacraldehydes and on further oxidation the ketones R.CO.R'. (*Cf.* J.C.S., Aug.)—W. G.

Lactic acid; Method for the estimation of small amounts of ——. S. W. Clausen. J. Biol. Chem., 1922, **52**, 263—280.

The method of Von Fürth and Charnass (J., 1910, 903) is slightly modified. Lactic acid is decomposed either by acid permanganate at 95° C. or by 50% sulphuric acid at 140° C., the aldehyde produced being carried by a current of air into excess of sodium bisulphite. The excess bisulphite is removed by addition of iodine, the end-point being adjusted to a definite blue to starch. Saturated sodium bicarbonate is then added until the blue coloration is just discharged, and the sulphite of the aldehyde-bisulphite compound titrated with saturated iodine, the end-point being determined by a blank control. The errors which arise when the method is applied to blood or urine may be reduced, but not entirely eliminated, by first extracting the lactic acid from the protein-free filtrate by ether, using a special extraction apparatus.—E. S.

Oxalic acid; Oxidation of —— [by permanganate] in the absence of other acids. J. C. Witt. J. Phys. Chem., 1922, **26**, 435—446.

OXALIC acid may be titrated with potassium permanganate without the addition of another acid, the oxalic acid functioning both as reducing agent and acid,

$$2KMnO_4+8H_2C_2O_4 \rightarrow K_2C_2O_4+2MnC_2O_4+8H_2O+10CO_2.$$

The end-point is marked by the appearance of a turbidity, followed by a slight permanent precipitate, and is affected by the temperature of titration, the concentration, and the presence of electrolytes. (*Cf.* J.C.S., Aug.)—J. S. G. T.

Acetic anhydride; Analysis of ——. C. E. Sage. Perf. Essent. Oil Rec., 1922, **13**, 172.

In the method described by Reclaire (J., 1922, 519 A) for the estimation of acetic anhydride the phenolphthalein used as indicator seems with certain samples to be peculiarly insensitive. The actual cause of this is obscure, but the peculiarity seems to run parallel with the development of the iodoform reaction when the sample in question is tested with sodium hydroxide and iodine. The unknown impurity giving this reaction may be traced back to the original acetic acid from which the anhydride was prepared, and it seems to be associated with faults in odour which sometimes develop in products prepared from the anhydride, *e.g.*, aspirin and synthetic "acetyl" perfumes. This insensitiveness of phenolphthalein may be overcome and a sharp end-point obtained if the titration is made by adding an excess of *N*/2 potassium hydroxide, allowing to stand for some time in the cold, until hydrolysis is complete, then adding a known quantity of *N*/2 acid and finishing off the titration with more *N*/2 potassium hydroxide. By this procedure errors due to heating under a reflux condenser will also be eliminated.—G. F. M.

Photocatalysis. II. Photosynthesis of nitrogen compounds from nitrates and carbon dioxide. E. C. C. Baly, I. M. Heilbron and D. P. Hudson. Chem. Soc. Trans., 1922, **121**, 1078—1088.

ACTIVATED formaldehyde, such as is photosynthetically produced from carbon dioxide and water under the influence of ultraviolet light or visible light in presence of a photocatalyst, reacts rapidly with nitrites with the formation of formhydroxamic acid, the reaction taking precedence to the polymerisation of the formaldehyde to reducing sugars. Photochemically activated formaldehyde possibly has the constitution H.C.OH, and its union with potassium nitrite would take place as follows:—

$$H\cdot C\cdot OH+O{:}N\cdot OK = \begin{array}{c}H\cdot C\cdot OH\\ \|\\ O{:}N\cdot OK\end{array} \rightarrow \begin{array}{c}H\cdot C\cdot OH\\ \|\\ N\cdot OK\end{array} +O$$

Formhydroxamic acid marks the first step in synthesis of the nitrogen compounds found in the plant, and it reacts further in various ways with activated formaldehyde to give α-amino acids and nitrogen bases, these condensations taking second order of preference, all excess of activated formaldehyde polymerising to hexoses. The photosynthesis of the nitrogenous compounds from formhydroxamic acid is extraordinarily rapid and soon goes far beyond the formation of simple compounds, the amino acids, pyrrol and pyridine derivatives condensing further to xanthine bases and substances of an alkaloidal nature. Two different alkaloids were isolated in this way, one a volatile oil with an odour resembling tobacco, and the other a solid of low melting point and an odour of burnt feathers. Both formed crystalline salts and gave positive tests with alkaloidal reagents. Positive evidence was also obtained of the formation of at least one substituted amino acid resembling histidine in its reactions. The photosynthesis of proteins would represent one stage further in the process, although positive evidence of their formation *in vitro* has not been obtained.—G. F. M.

Urea; Synthesis of —— from ammonia and carbon dioxide. N. W. Krase and V. L. Gaddy. J. Ind. Eng. Chem., 1922, 14, 611—616.

Experiments were made on the synthesis of urea from ammonia and carbon dioxide using a small experimental plant. The process finally developed consisted in preparing an initial charge of ammonium carbamate by condensing a mixture of ammonia, carbon dioxide, and about 1% of water vapour in a condenser maintained at about 25° C. and provided with a rotating scraping blade. The carbamate charge is formed by pressure into briquettes of such size as to fit easily into the autoclave, which is kept continuously at 150° C. The density of packing of the charge in the autoclave was found to influence greatly the percentage conversion into urea, a density of 0·3—0·5 g. per c.c. being suitable. High temperatures also favourably influence the yield, but the great pressure generated sets a limit to the temperature which can in practice be employed; 150° C. involving pressures of 1200—1800 lb. per sq. inch, is therefore as high as can conveniently be utilised. Heating is continued for 4 hours. The liquid converted charge containing about 40% of urea is slowly released into a still, and the unconverted ammonium carbamate distilled off at about 55° C. in a current of carbon dioxide, and recondensed together with additional ammonia to form a new charge of carbamate.—G. F. M.

Water, alcohol, and ether; Specific gravities and refractive indices at 15° C. of mixtures of ——. A. Sanfourche and A. M. Boutin. Bull. Soc. Chim., 1922, 31, 546—551.

The specific gravities and refractive indices at 15° C. of a large number of mixtures of water, alcohol, and ether in varying proportions are tabulated and the results are also shown in triangular diagrams.—W. G.

Spirit of camphor; The system camphor-alcohol-water in relation to the titration of ——. K. Scheringa. Pharm. Weekblad, 1922, 59, 389—395.

From the results of tests in which solutions of camphor in alcohol were treated with water until a permanent separation occurred, and the increase of weight determined, it is shown that many different mixtures can be prepared to satisfy the requirements of the Dutch Pharmacopœia, and that in analysing camphor spirit as recommended by titration with water, the temperature must be kept between 20° and 25° C., and the amount of camphor which can be added and held in solution at 15° C. should be specified.—S. I. L.

Essential oil of Myrica Gale. M. Schoofs. J. Pharm. Belg., 1921, 3, 769—773. Chem. Zentr., 1922, 93, I., 1340—1341.

Two essential oils were isolated from *Myrica Gale* by steam distillation. The one which was insoluble in the aqueous distillate had the following constants: sp. gr. 0·9068 at 15° C., $[\alpha]_D = -8° 46'$, $n_D^{25} = 1·4820$, acid value 1·5, saponif. value 17·8, iodine value 168·84, combined alcohols $(C_{10}H_{18}O)$ 4·4%, linalyl acetate 5·6%, free alcohols 11·1%. The other oil was extracted from the distillate and had the following constants: sp. gr. 0·8956 at 15° C., $[\alpha]_D = -5·9°$, $n_D^{25} = 1·4656$, acid value 1·8, saponif. value 18·19, combined alcohols 4·5%, linalyl acetate 5·73%, free alcohols 7·06%, iodine value 56·70.
—G. F. M.

Lantana Camara; Essential oil of ——. K. L. Moudgill and P. N. Vridhachalam. Perf. Essent. Oil Rec., 1922, 13, 173—174.

The essential oil of *Lantana Camara*, a wild shrub growing on waste lands in Southern India, was isolated by steam distillation, with a yield of about 0·2%. It is a greenish-yellow, slightly fluorescent oil, having an odour recalling that of sage. It is soluble in 5 vols. of 97% alcohol, and has the following characters:—Sp. gr. 0·8842 at 30°/4° C., $[\alpha]_D^{30} = +14·7°$, n=1·4899, acid value 1·6, saponif. value 4·6, acetyl value 23·4, aldehyde content 2·4%. On repeated fractionation three fractions were finally obtained: 55°—75° C. at 12 mm., 12% by volume; 75°—125° C., 8%; and 125°—130° C. at 12 mm., 74%. The first fraction proved to be *l*-α-phellandrene. The second fraction contained the odoriferous principles of the oil, and from the constants these appear to be mainly an aldehyde and an alcohol. The third fraction was mainly a bicyclic sesquiterpene closely resembling caryophyllene, although the solid caryophyllenic alcohol could not be obtained. On distilling this fraction under ordinary pressure the distillate differed considerably, particularly in rotation, from the original. The change does not appear to be simply a racemisation.—G. F. M.

Patents.

Synthetic camphor; Manufacture of ——. L. and E. Darrasse and L. Dupont. E.P. 164,357, 6.6.21. Conv., 9.6.20.

A solvent such as chlorinated hydrocarbon, turpentine, and anhydrous oxalic acid are heated together to the boiling point of the mixture, whereby bornyl oxalate is produced, the reaction taking place rapidly in the absence of inorganic chlorides. The bornyl oxalate is rapidly saponified by an aqueous solution of soda. It can be separated from the small quantity of uncombined turpentine by distilling off the latter. The reaction takes place most rapidly in tetrachloroethane solution.—H. C. R.

Medicinal compound [reduced araroba extract] and method of producing the same. J. F. Schamberg and G. W. Raiziss, Assrs. to Dermatological Research Laboratories. U.S.P. 1,417,771, 30.5.22. Appl., 21.4.20.

The amorphous powdered extract of araroba is dissolved in acetic acid and treated at the boiling point with metallic tin and hydrogen chloride. The reaction being completed, the solution is filtered and cooled, after removal of the acetic acid. The product separates out in minute yellow crystals, m.p. 190° C.; it is slightly soluble in ether and methyl alcohol, more soluble in acetic acid, chloroform, benzene, and ethyl alcohol.—G. F. M.

Urea; Producing —— from cyanamide. E. Lie. U.S.P. 1,419,157, 13.6.22. Appl., 10.6.20.

See E.P. 170,329 of 1920; J., 1922, 391 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Light sensitivity; Interpretation of —— in photography. T. Svedberg. Phot. J., 1922, 62, 310—320.

The author discusses the application of Einstein's law of the photochemical equivalent to various photochemical reactions, and to the particular case of the photographic process. He draws a distinction between plate-sensitiveness, grain-sensitiveness, and sensitiveness of the silver halide material of the grain. A description follows of some of his previous statistical work on the occurrence and distribution of developable centres in the grains, and of experiments which prove that in the case of the small spherical grains of a slow emulsion these centres are distributed on the surface.—W. C.

[Photographic] reduction with ammonium persulphate; Action of soluble chlorides and bromides on ——. S. E. Sheppard. Phot. J., 1922, **62**, 321—333.

The characteristic differential reducing action of ammonium persulphate is not necessarily due to the presence of chloride ions. The presence of low concentration of silver ions and of acid reduce the maximum rate of reduction, but do not eliminate the differential action of low densities. Bromide has no greater effect than chloride. The experimental evidence seems to favour the "dispersoid" theory of Lüppo-Cramer rather than the "catalytic" theory. The results obtained on reduction with ammonium persulphate are compared with those obtained by Higson (J., 1922, 234 A) with potassium persulphate. The effect of acid concentration on the reaction velocity is discussed, together with the actual mechanism of the reaction. —W. C.

Patents.

[Photographic] negatives; Process for the manufacture of —— *from opaque originals.* M. Ullmann. E.P. 156,691, 7.1.21. Conv., 7.1.20.

In the manufacture of negatives for photolithography from originals that do not allow light to pass through them, the chromate colloid coating is rendered insoluble in and impervious to water, by treatment with salts or basic or acid dyestuffs, *e.g.*, by dyeing in a dilute solution of pentamethyl-*p*-rosaniline and then bathing in a dilute aqueous solution of diaminostilbene-disulpho acid diphenol. —W. C.

Gelatin printing plates; Process for the production of ——. H. Renck. E.P. 168,578, 1.3.21. Conv., 2.9.20.

A printing relief surface is produced by exposing a bichromated gelatin plate behind a negative, thus causing the exposed parts to become hardened or insoluble, then treating with water to swell the unexposed parts, and subsequently exposing to dry heat to evaporate the water absorbed by the unexposed parts, thus causing these parts to sink lower than the hardened exposed parts.—W. C.

Sensitive plates and films for X-ray photography. N. E. Luboshey. E.P. 181,087, 2.3.21.

A layer of intensifying screen material (*e.g.*, calcium tungstate) is enclosed between the sensitive emulsion and the glass or film support, and forms a permanent part of the photographic plate or film. The material may be of the "single" or "duplex" form. In the former the glass or film support is coated on one side with intensifying screen material, and on this the sensitive emulsion is laid. In the "duplex" form each surface of the support is coated with an intensifying screen coating, and to each of these coatings is applied a layer of sensitive emulsion. The X-ray plates or films thus prepared may be enclosed within light-proof envelopes of opaque material coated with intensifying screen material on one or both sides of one or both sheets of the envelope, the envelopes being removed before development. X-ray plates or films as described may have an additional screen or screens affixed to the actual emulsion surface or surfaces by means of adhesive substances which allow of the removal of the screen or screens without wetting. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2243 of 1915, and 125,490, and in pursuance of Sect. 8, Sub-sect. 2, to E.P. 163,903; J., 1916, 386; 1919, 389 A.)—W. C.

Sensitising [photographic] papers and other fabrics; Machines for ——. B. J. Hall. E.P. 181,460, 10.3.21.

The floor space occupied by the drying apparatus for sensitive papers and other fabrics after coating is reduced to a minimum by passing the paper after sensitising over a stationary heated body termed the radiator, the uncoated side of the paper being in direct contact with the heated radiator surface. In the event of sensitisers being used which would be injured or prevented from sliding by direct contact of the paper with the radiator, an endless revolving band of canvas or other material is interposed between the radiator and the paper.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Behaviour of —— *on heating with water under pressure.* A. Logothetis and G. Gregoropoulos. Z. ges. Schiess- u. Sprengstoffw., 1922, **17**, 89—90.

The stability of nitrocellulose can be increased by heating it in an autoclave with water. The maximum stability is usually reached after one or two treatments for 2 hrs. The pressure should not exceed 2 atm., or decomposition of the fibrous structure may result, together with loss of nitrogen and a lowering of the temperature of explosion. —H. C. R.

XXIII.—ANALYSIS.

Dialyser; A rapid ——. A. Gutbier, J. Huber, and W. Schieber. Ber., 1922, **55**, 1518—1523.

The apparatus consists of a wooden disc supporting a framework composed of glass rods in the form of a hollow cylinder. The membrane is passed over the framework and secured in its natural folds to the wooden disc. A stirrer is placed within the vessel, which is mounted in such a manner that the frame and stirrer can be rotated in opposite directions. The apparatus is placed in an inverted, tubulated bell-jar, through the tubulus of which water is admitted; the water can be heated or cooled by coils placed in the jar, and the level of the water and its discharge are governed by a lever arrangement. Comparative experiments show the dialyser to be much more rapid in its action than those of Graham or Zsigmondy and Heyer (J., 1910, 1249). In addition to rapidity of action, the following advantages are claimed: exclusion of external air from the internal liquid, from which, however, samples may be readily taken; small liability to change in volume, particularly to dilution of the internal liquid; great safety in action, [illegible] only a single piece of parchment is used; simple method of securing a continuous change of the external water; the possibility of dialysis at raised or lowered temperatures without complicated arrangements.—H. W.

Sampling horn: Kellogg's ——. J. W. Kellogg. J. Ind. Eng. Chem., 1922, **14**, 631.

A new type of horn for obtaining official samples of foodstuffs, fertilisers, etc., for analysis consists of a brass tube 31·5 inches long and 1$\frac{1}{16}$ inches internal diameter, which can be disjointed in the middle so as to be less cumbersome to carry about. The upper section has a four-inch handle, and the threaded end is protected with a screw-cap. The lower section has a bevelled, sharpened, knife-edge point, *which is protected with a cap. Slots run longitudinally down the tube, one edge of which is sharpened, which aids in forcing the sample into the horn. The slots are ¼ inch in width, and are designed especially to facilitate the removal of the sample with a spatula.—G. F. M.*

Micro-analysis; Furnace and burner for use in ——. E. Diepolder. Chem.-Zeit., 1922, **46**, 455.

A **burner** for use in micro-chemical combustions consists of a T-shaped tube; the gas is admitted through the vertical stem, which is provided with an air inlet and regulator, whilst the horizontal arm is perforated and constitutes the burner. The perforations may be closed separately so that the number of flames may be regulated at will.
—W. P. S.

Pycnometry. R. Saar. Chem.-Zeit., 1922, **46**, 433-435.

Tables and formulæ are given for calculating specific gravities determined at one temperature into similar values at another temperature.
—W. P. S.

Soxhlet apparatus; Extraction of small quantities of liquids in a ——. H. Handorf. Z. angew. Chem., 1922, **35**, 257—258.

The liquid to be extracted is placed in the inner tube (see Figs.). If the liquid is extracted by a solvent lighter than itself, the condensed solvent drops into the funnel (Fig. 1) and rises in drops from the rose through the liquid. If the liquid is extracted by a solvent heavier than itself, a short funnel ending in a capillary rests on the top of the tube (Fig. 2), and the condensed solvent falls through the liquid and rises in the inner tube. The apparatus is suited for the extraction of liquids containing colloidal substances.—H. [illegible]

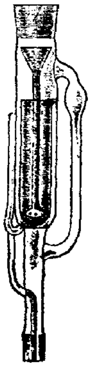

Fig. 1.

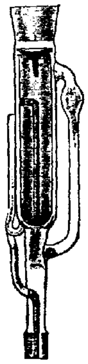

Fig. 2.

Aluminium and iron; Separation of —— by means of o-phenetidine. K. Chalupny and K. Breisch. Z. angew. Chem., 1922, **35**, 233—234.

Ferrous salts are not affected by *o*-phenetidine, whilst aluminium salts are precipitated completely by this reagent. To ensure reduction of any ferric salt present, the solution containing iron and aluminium salts is acidified slightly with hydrochloric acid and treated for 10 mins. with a current of hydrogen sulphide; carbon dioxide is then passed through the solution until all excess of hydrogen sulphide has been expelled. Ammonium carbonate is added until a precipitate forms; this is dissolved by adding a small quantity of dilute hydrochloric acid, and the mixture is treated with an excess of 5% alcoholic *o*-phenetidine solution. The flask is closed, the mixture heated at 60° C., and the precipitate collected, ignited, and weighed as Al_2O_3. To determine aluminium in the presence of copper and other metals, the copper must be separated electrolytically, the iron and aluminium then precipitated as basic acetates, the latter dissolved in dilute hydrochloric acid, and the aluminium precipitated from this solution as described.—W. P. S.

Manganese; Determination of ——. L. W. Winkler. Z. angew. Chem., 1922, **35**, 234—235.

The method described previously (J., 1921, 607 A, 751 A) for the determination of cadmium as phosphate may be applied to the determination of manganese; 1 mg. is deducted from the weight of the precipitate obtained when the latter weighs from 0·2 to 0·3 g. Sodium chloride must not be present in the solution, but potassium chloride does not interfere.—W. P. S.

Magnesium; Colorimetric method for the estimation of small amounts of ——. F. S. Hammett and E. T. Adams. J. Biol. Chem., 1922, **52**, 211—215.

The method is designed for application to urine, blood, and tissue extracts, and is a modification of Kramer and Tisdall's method (J. Biol. Chem., 1921, **48**, 223). The precipitate of ammonium magnesium phosphate obtained in the latter method is dissolved in $N/100$ hydrochloric acid and the phosphorus estimated colorimetrically by Bell and Doisy's method (J. Biol. Chem., 1920, **44**, 55). The amount of magnesium is then calculated from this result.—E. S.

Potassium ferrocyanide; Potentiometric titrations by means of ——. II. Potentiometric titration of zinc. I. M. Kolthoff. Rec. Trav. Chim., 1922, **41**, 425—437.

The results obtained in potentiometric titration of zinc by means of potassium ferrocyanide solution are reliable, and the method is convenient in practice. Although the method is applicable at ordinary temperatures, it is quicker at 70° C., and at the higher temperature the change in potential is more marked. As previously mentioned (J., 1922, 485 A), ferricyanide should be added to the ferrocyanide solution; the quantity recommended is 1 g. per litre. The molecular concentration of the ferrocyanide used was $\frac{1}{10}$. The best results are obtained in weak acid solution; 1 or 2 c.c. of $4N$ sulphuric acid is sufficient, and excess should be avoided, as the solubility of the precipitate of potassium zinc ferrocyanide is thereby increased, and this causes a decrease in the change of potential when the end-point is reached. Results obtained in neutral solution are from 1% to 1·5% too low. At ordinary temperatures the presence of a quantity of potassium sulphate or ammonium sulphate gives results which are usually about 0·5% too high. The latter salt at 70° C. introduces error in the opposite direction, as does ammonium chloride at ordinary temperatures. The titration of ferrocyanide by means of zinc may also be carried out with speed and accuracy by the potentiometric method.
—H. J. E.

Arsenic; Colorimetric determination of —— by means of quinine molybdate. D. Chouchak. Ann. Chim. Analyt., 1922, **4**, 138—142.

Quantities of arsenic as small as 0·00002 mg. yield a turbidity with quinine molybdate reagent. The arsenic solution under examination is treated with nitric acid, evaporated to dryness, and the residue treated with 0·5 c.c. of 17·5% nitric acid, 4·5 c.c. of water, and 20 c.c. of quinine molybdate reagent. The turbidity or opalescence produced is compared with that given by a known quantity of arsenic under similar conditions. The reagent, which is *saturated with quinine arsenomolybdate, is prepared by dissolving 0·5 g. of quinine hydrochloride in 10 c.c. of water, adding 5 c.c. of arsenic acid* solution (containing 0·01 mg. of arsenic per c.c.), 10 c.c. of 17·5% nitric acid, and 1 c.c. of sodium molybdate solution (3·5 g. of sodium carbonate and 9·5 g. of molybdic acid per 100 c.c.). After a few minutes the mixture is diluted to 120 c.c. and filtered through a filter-paper washed previously with dilute nitric acid and hot water. In the presence of heavy metals a preliminary separation of the arsenic by distillation with hydrochloric acid, potassium bromide, and hydrazine sulphate is necessary. The distillate is then oxidised with nitric acid, evaporated to dryness, and the test applied to the residue.—W. P. S.

Electrolysis; Rapid —— without rotating electrodes. G. Edgar and R. B. Purdum. J. Amer. Chem. Soc., 1922, **44**, 1267—1270.

Rapid electrolysis may be carried out without the use of rotating electrodes if the solution is stirred by means of a current of air. An apparatus is described for such analysis. The cathode is a platinum gauze cylinder in the centre of which is a spiral platinum electrode. The electrodes are contained in a glass tube, 31 mm. diam., to which are sealed three glass "air lifts" connected in a single tube at the bottom and entering symmetrically about halfway up the wide tube, the seals being made tangentially. When air is forced into the apparatus half filled with liquid, both vertical and rotational stirring is effected. Experiments on the electrolytic determination of copper, zinc, iron, and nickel are described which show that the results obtained with this apparatus are equally as good as those obtained with rotating electrodes.—J. F. S.

Adsorption of iron by precipitates of manganese dioxide. M. Geloso. Comptes rend., 1922, **174**, 1629—1631. (*Cf.* Nicolardot and others, J., 1920, 351 A.)

When manganese is precipitated as its dioxide by the addition of ammonium persulphate to an acid solution of manganese sulphate containing some iron salt, the amount of iron adsorbed by the precipitate varies directly as the concentrations of the iron and manganese and inversely as the acidity of the solution. The presence of ammonium sulphate does not affect the results. The iron adsorbed is mostly in the form of hydroxide.—W. G.

Permanganate; Oxidation of manganese to —— in alkaline solution. J. Heslinga. Chem. Weekblad, 1922, **19**, 274.

As little as 0·005 mg. of manganese may be detected by oxidising to permanganate in boiling solution in presence of bromine water, potassium hydroxide, and excess of copper sulphate. The coloration develops immediately. The reaction is not suitable for the colorimetric estimation of manganese. (*Cf.* J.C.S., August.)—S. I. L.

Radium; Direct determination of small quantities of —— by the penetrating rays. B. Szilard. Comptes rend., 1922, **174**, 1695—1698.

The electrometer previously described (*ibid.*, 1922, **174**, 1618) has been modified so as to provide a portable instrument working without either a high-tension battery or a projection mirror. By means of it rapid measurements can be made of the penetrating rays. The sensitiveness of the instrument corresponds to 10^{-4} U.E.S. Working with 500 g. of material containing 10^{-9} g. of radium per g. the results were accurate to within 2·5%.—W. G.

Cyanogen; Determination of ——. H. Yanagisawa. Yakugakuzasshi (J. Pharm. Soc. Japan), 1922, No. 483, 369—377.

The cyanogen compound is heated with dilute sul*phuric acid in a sealed tube at 200° C. for 4 hours, whereby cyanogen is converted into ammonia.* After cooling the resulting mixture is rendered alkaline with caustic soda, distilled into *N*/4 sulphuric acid, and the excess of acid titrated with *N*/4 ammonia as usual.—K. K.

Precipitates; Carrying down [of soluble salts] by ——. P. Dutoit and E. Grobet. J. Chim. Phys., 1922, **19**, 328—330.

The carrying down of soluble salts by precipitates is explained as due to the adsorption of these substances on the surface of the precipitate, whereby the soluble substance locally attains a value which exceeds its solubility product. This is prevented by stirring the solution very rapidly during the addition of the reagent, and in this way very good quantitative results may be obtained. (*Cf.* J. C. S., Aug.)—J. F. S.

Gases; Determination of suspended impurities in ——. W. W. Scott. J. Ind. Eng. Chem., 1922, **14**, 432—433.

Dust particles or liquid mist in gases can be detected by their visibility in a beam of solar or arc light. The observation is best made in a direction towards the source of light. A filter of loose dry asbestos, 2 in. thick, effectually removes liquid or solid matter. The estimation of liquid suspended in gases, for instance, sulphuric acid in contact process gases, may be carried out by aspirating the gas through a filter of blue Cape asbestos, extracting the asbestos with water, and titrating the solution with standard alkali; the gas is measured by a dry gas meter.—H. M.

Pyrogallol solutions for gas analysis; Oxygen absorption and concentration of ——. F. Hoffmann. Z. angew. Chem., 1922, **35**, 325—328.

Experiments to determine the absorptive powers for oxygen of solutions prepared with different proportions of pyrogallol and caustic potash were made by introducing successive quantities of 60 c.c. of air into a pipette containing 0·5 c.c. of the solution under test, the results being added together and tabulated in a Gibbs triangular diagram for the ternary system pyrogallol, caustic potash, and water. A line of maximum absorptions was found corresponding to mixtures containing pyrogallol and caustic potash in the proportion of 3 to 2. In the field to one side of this line, corresponding to a smaller proportion of caustic potash, the absorptive power falls sharply. From practical considerations the optimum proportion is stated as 20 pts. of pyrogallol, 20 pts. of potash, and 60 pts. of water, or 40 g. of pyrogallol in 90 c.c. of water with 70 g. of concentrated potash solution of sp. gr. 1·55.—H. M.

Oxygen; Method for the estimation of minute amounts of —— and its application to respiratory air. H. M. Sheaff. J. Biol. Chem., 1922, **52**, 35—50.

The method is intended mainly for use in following the oxygen consumption of plant and animal tissue under different conditions. By means of the apparatus, which is described and illustrated, it is stated that oxygen can be estimated in amounts as small as 1×10^{-7} g. The method depends upon the conversion of the oxygen, in the presence of nitric oxide and sodium hydroxide, into sodium nitrite, and the estimation of the latter colorimetrically by means of sulphanilic acid and α-naphthylamine.—E. S.

Organic compounds; Determination of chlorine in ——. J. Klimont. Chem.-Zeit., 1922, **46**, 521—522.

When monochloroacetic acid is neutralised, then boiled under a reflux condenser with alcoholic potassium hydroxide solution and the excess of the latter titrated subsequently, the saponification value thus obtained is a measure of the chlorine in the molecule, the substance being converted quantitatively into potassium acetate and potassium chloride. The method, however, yields unsatisfactory results when applied to the determination of chlorine in acetylene dichloride, monochlorohydrin, monochloroacetone, dichloroacetone, α-chloronaphthalene, bornyl chloride, pinene hydrochloride, trichloroethane, acetylene tetrachloride, and α-dibromohydrin, either because the molecule of the substance is incompletely hydrolysed or because secondary reactions occur.—W. P. S.

Trypsin; Method for the quantitative determination of ——. *A modification of Gross' method.* S. Kai. J. Biol. Chem., 1922, **52**, 133—136.

The relative strengths of trypsin preparations are estimated by measuring the time taken by equal amounts of each to digest 25 c.c. of a casein solution, the time of digestion being inversely proportional to the concentration of the trypsin. The end point of digestion is determined by adding a solution of sodium acetate and acetic acid to test portions withdrawn from time to time, no precipitate being produced when digestion is complete.—E. S.

Sulphur; Rapid estimation of ——. *I.* L. Losana. Giorn. Chim. Ind. Applic., 1922, **4**, 204—206.

When a sulphur compound is heated with powdered iron out of contact with the air and the mass thus obtained then treated with hydrochloric acid, the whole of the sulphur is liberated as hydrogen sulphide. The latter may be absorbed by zinc acetate solution and the sulphide so formed titrated with standard iodine solution. The amount of the substance taken for analysis is 1 g., 0·5 g., or 0·1 g., according as the percentage of sulphur present is 0—5, 5—10, or more than 10. A mixture of the substance with 2 g. of pure powdered iron and 0·5 g. of sodium hydrogen carbonate is introduced into a hard glass tube, covered with a layer of the iron several mm. in depth, and heated to incandescence for a few minutes. The treatment of the mass with acid is carried out in a small round-bottomed flask with a ground stopper sealed to the tube of a reflux condenser, the upper end of the tube being bent over to pass through the cork of a bulbed absorption tube charged with about 150 c.c. of 2·5% zinc acetate solution acidified slightly by acetic acid. A gas delivery tube dipping into a little water in the flask is sealed horizontally through the head of the ground stopper, and ends in a vertical cross-piece to form a T-piece. The top of the latter is connected with a source of carbon dioxide and the bottom with a rather long rubber tube joined to a tapped funnel. The hard glass tube containing the heated mixture is allowed to cool somewhat, and is dropped while still hot into the flask and thus broken by the cold water. A rapid current of carbon dioxide, washed by permanganate solution and then by water, is passed through the flask, and hydrochloric acid introduced through the funnel. When the reaction slackens the flask is heated gently, and when evolution of gas ceases carbon dioxide is passed briskly through the apparatus for about five minutes. The liquid from the absorption bulbs is transferred to a beaker, diluted to 300—400 c.c., mixed with a known volume in excess of standard iodine solution, allowed to settle, and titrated with thiosulphate solution, the sulphur being calculated from the equation, $ZnS+I_2=ZnI_2+S$. The content of sulphur in the reagents used is determined by a blank experiment. Tests made on flowers of sulphur and on copper, lead, barium, and cobalt sulphates gave virtually theoretical results. The estimation may be completed in about 40 minutes. When the estimation is to be made on an organic compound, this is first mixed with copper oxide or lead chromate and the mixture heated in a porcelain crucible, or, if the compound is volatile, in a narrow glass tube in which it is covered with a deep layer of the oxidising material. —T. H. P.

Oxidation by means of sulphuric acid and chromates. L. J. Simon. Comptes rend., 1922, **174**, 1706—1708.

For the wet combustion of organic compounds by means of chromic acid the most satisfactory results are obtained by the use of a mixture of concentrated sulphuric acid and silver chromate, using about 15 c.c. of the acid and 12 g. of the chromate for about 0·1 g. of substance. This oxidising mixture completely oxidises acetates or acetyl compounds, whereas chromic anhydride and sulphuric acid together do not.—W. G.

COMPLETE SPECIFICATIONS ACCEPTED.

35,975 (1920). Brutzkus. Effecting chemical reaction in the interior of compressors. (155,776.) July 19.

786 (1921). Lilienfeld. Manufacture of colloidally soluble substances and suspensions or emulsions. (156,725.) July 26.

2003 (1921). Wade (Schneible). *See* XVIII.

6746 (1921). Gardner. Mixing and/or disintegrating machines. (182,850.) July 26.

9677 (1921). Dine and Sieff. Preparation for removing scale from boilers and preventing its formation. (182,545.) July 19.

12,600 and 14,501 (1921). Heenan and Froude, and Walker. Concentration of brine etc. used as circulating medium in refrigerating apparatus. (182,982.) July 26.

19,114 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Preparation of colloids and colloidal solutions. (182,696.) July 19.

6090 (1922). Marx. Dehydrating plastic and other materials. (183,097.) July 26.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Auld. 19,974. *See* III.

Batchelor. Production of artificial light. 19,505. July 15.

Bitumen Products, Ltd., and Illemann. Solid oil fuel. 19,074. July 12.

Burls. Treatment of carbonaceous substances. 19,978. July 20.

Calder and Lennox. Inflammable vaporisable liquid fuels. 20,068. July 21.

Calder and Lennox. Gas-producing plant. 20,0[illegible]. July 21.

Carbic, Ltd., and Them. 20,060. *See* VII.

Chown. Carbonising and distilling carbonaceous material. 18,925. July 10.

Coppée et Cie. Concentrating etc. carbonaceous slimes. 19,730. July 18. (Belg., 19.7.21.)

Duffield. Pulverising coal etc. 19,410. July 14.

Fabry. Coke manufacture. 19,346. July 14.

Harris and Rose. Gaseous fuel. 19,161. July 12.

Hood, and Oil Refining Improvements Co. Purification of oils. 20,129. July 22.

Kern. Obtaining mineral oils from bituminous rocks. 20,024. July 21. (Ger., 27.7.21.)

Ormandy. Manufacture of fuel briquettes. 20,046. July 21.

Quinan. Pyrolytic distillation. 20,052. July 21. (S. Africa, 6.8.21.)

Remfry. Treatment of hydrocarbons. 20,151. July 22.

Remfry. Treatment of cracked spirit. 20,152. July 22.

Simon-Carves, Ltd. Treating coal etc. slimes. 19,877. July 20.

Walker and White. Gas generators. 19,248. July 13.

COMPLETE SPECIFICATIONS ACCEPTED.

365 (1921). Freyn, Brassert, et Cie. Apparatus for washing gas. (156,490.) July 19.

1230 (1921). Polysius. Low-temperature carbonisation. (157,318.) July 26.

1785–6 (1921). Mather. Distillation of crude oil and other liquids. (182,827–8.) July 26.

7160 (1921). Plauson and Vielle. Manufacture of hydrocarbons from coal etc. or its distillation products. (182,852.) July 26.

7407 (1921). McDonald. Process for making gas. (159,886.) July 26.

9646 (1921). Bonnard. Carbonising furnaces and retorts. (182,542.) July 19.

10,303 (1921). Igranic Electric Co. *See* XXIII.

10,409 (1921). Bowen. Production of artificial fuel. (182,578.) July 19.

11,041 (1921). Wood. Gas retorts. (161,918.) July 26.

11,838 (1921). Salerni. Apparatus for distilling carbonaceous materials. (182,601.) July 19.

15,203 (1921). Maclaurin. Enriched water-gas plant. (182,648.) July 19.

19,402 and 19,994 (1921). Warden. Coking-retort ovens. (182,697 and 182,702.) July 19.

22,878 (1921). Holland. Recovery of coal from water etc. (171,670.) July 26.

34,654 (1921). L'Air Liquide. *See* VII.

10,079 (1922). Polysius. Low-temperature carbonisation. (178,126.) July 26.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Auld. Treatment of hydrocarbons. 19,974. July 20.

Insulators, Ltd., and Winfield. Treatment of tar, pitch, etc. 19,257. July 13.

Murphy. 19,041. *See* IX.

Remfry. 20,151. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

4557 (1921). Atack. Oxidation of hydrocarbons. (182,843.) July 26.

9361 (1921). Blumner. Distillation of tars or oils. (182,868.) July 26.

10,603 (1921). Koppers Co. Purification of phenol-contaminated liquors. (161,976.) July 26.

12,974 (1921). Bismarckhütte. Separation of water from coal tar. (163,011.) July 19.

20,417 (1921). British Dyestuffs Corp., Green, and Green. Manufacture of phthalimide. (183,044.) July 26.

30,471 (1921). Barrett Co. Purification of naphthalene. (172,937.) July 19.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATIONS ACCEPTED.

688 (1921). Plauson and Vielle. *See* XIII.

13,624 (1921). Bayer u. Co. Manufacture of copper compounds of substantive azo dyestuffs. (165,083.) July 19.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Briggs, Palmer, and British Cellulose and Chem. Manuf. Co. Manufacture or treatment of artificial silk, films, etc. 19,488. July 15.

Caldecott, Horrocks, Rushworth, and Rushworth and Co. Treatment of fibres for brooms etc. 20,007. July 21.

Cook, and Cook and Co. Treatment of cotton etc. 19,647. July 18.

Dreyfus. Manufacture of compositions with cellulose derivatives. 19,255–6. July 13.

Kämpf. Manufacture of artificial threads etc. of viscose. 20,003–4. July 21. (Ger., 6.8.21.)

Little Inc. Cellulose derivative and process of preparing same. 18,934. July 10. (U.S., 10.4.20.)

N. V. Hollandsche Kunstzijde Ind. Manufacture of artificial silk threads etc. from viscose. 19,953. July 20. (Ger., 20.7.21.)

Wickel. Manufacture of metal-coated paper. 19,589. July 17. (Ger., 15.7.21.)

COMPLETE SPECIFICATIONS ACCEPTED.

36,001 (1920). Köln-Rottweil A.-G. Manufacture of cellulose material. (156,095.) July 19.

753 (1921). Ehrenthal. Manufacture of cotton substitutes. (156,709.) July 19.

1911 and 22,980 (1921). Clavel. Treatment of cellulose acetate or products made therewith. (182,830.) July 26.

20,703 (1921). Granton (Niessen). Manufacture of bristles for brooms, brushes, etc. from bamboo, madagascar, pepper, and similar reeds. (183,049.) July 26.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Bleachers' Assoc., Ltd., and Kenworthy. Bleaching etc. kiers. 19,541. July 17.

Farrar, Lepine, and Whitehead. Dyeing-machines. 19,455. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

4638 and 29,734 (1921). Clavel. Treatment of union or mixed fabrics. (182,844.) July 26.

10,331 (1921). Brandwood, Brandwood, and Brandwood. Dyeing, bleaching, etc. of textile fibres. (182,575.) July 19.

28,921 (1921). Bloxam (A.-G. f. Anilinfabr.). Dyeing skins, hairs, etc. (183,078.) July 26.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Ashworth. Apparatus for producing bisulphites etc. 19,661. July 18.

Bäckström and Cederberg. Apparatus for catalytic oxidation of ammonia. 19,405. July 14.

Blattner (Grouchkine). Manufacture of caustic alkali. 19,615 and 20,663. July 17 and 21.

Blumenfeld and Weizmann. Titanium compounds. 19,154–6. July 12.

British Oxygen Co., and Houseman. Manufacture of sulphur dioxide. 19,820–1. July 19.

Carbic, Ltd., and Them. Manufacture of calcium carbide cakes. 20,060. July 21.

Charlesworth and Johnson. Machine for drying and neutralising sulphate of ammonia etc. 19,546. July 17.

Cochran and Marsh. 19,738. *See* X.

Farrell. Caustic soda recovery apparatus. 20,100. July 22.

Mond (Chem. Fabr. Griesheim-Elektron). Manufacture of alumina. 19,700. July 18.

Soc. l'Air Liquide. 20,130. *See* I.

COMPLETE SPECIFICATIONS ACCEPTED.

1911 (1921). Helbronner and Pipereaut. Manufacture of sulphuric acid. (157,281.) July 26.

6801 (1921). Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Manufacture of ammonia. (159,878.) July 19.

7533 and 23,759 (1921). Broadbridge, Edser, and Sellers. Treatment of caliche. (182,859.) July 26.

7597 (1921). Goldschmidt. Manufacture of magnesium chloride. (161,165.) July 26.

9832 (1921). L'Air Liquide. Synthesis of ammonia. (160,811.) July 19.

10,771 (1921). Chem. Fabr. Griesheim-Elektron. Production of stable compounds of calcium hypochlorite. (182,927.) July 26.

16,164 (1921). Courtaulds, Ltd., and Jones. Manufacture of caustic soda. (182,661.) July 19.

32,216 (1921). Weyman. Neutralising and drying sulphate of ammonia. (183,089.) July 26.

34,654 (1921). L'Air Liquide. Manufacture of hydrogen. (175,605.) July 19.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Boulton, Ltd., and Johnson. Cloth for filter presses for treating potters' clay etc. 19,535. July 17.

Bundy. Glass etching. 19,783. July 19.

Damard Lacquer Co., Lloyd, Potter, and Robinson. Pottery etc. 19,366. July 14.

COMPLETE SPECIFICATIONS ACCEPTED.

9749 (1921). Mathys (Bicheroux, Lambotte et Cie.). Manufacture of raw plate glass. (182,551.) July 19.

10,168 (1921). Clark. Electro-fining glass furnace. (161,192.) July 19.

19,329 (1921). Ges. f. Tuff- u. Ton-Technik. Production of ceramic materials, glass, and glazings. (166,558.) July 19.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Bühler. Manufacture of Portland cement. 20,005. July 21. (Switz., 15.10.21.)

Davies. Oxychloride cement coverings. 19,553. July 17.

Lanhoffer. Roasting or calcining cement. 19,149. July 12. (Fr., 3.4.22.)

Murphy. Soluble tar, bituminous etc. compound for roads etc. 19,041. July 11.

Samuel. 19,174. *See* XI.

COMPLETE SPECIFICATION ACCEPTED.

3950 (1921). Lyon. Artificial maturing or seasoning of wood. (182,504.) July 19.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Ashcroft. Treatment of sulphide ores etc. 19,422. July 14.

Ashcroft. Recovering tin from tinplates, alloys, etc. 19,483. July 15.

Ashcroft. Separating metals from fused melts of zinc and/or lead chloride. 19,616. July 17.

Beardmore and Co., and Neilson. Cleaning out open-hearth furnaces. 18,849. July 10.

Cochran and Marsh. Reclaiming spent pickling solution. 19,738. July 18. (U.S., 3.8.21.)

Craig, Pearson, and Durelco, Ltd. Manufacture of tungsten. 19,197. July 12.

Hansgirg. 18,928. *See* XI.

Imray (Dietzsch and Prain). Treatment of copper ores. 18,897. July 10.

Levoz. Side-blast converter furnaces. 19,051. July 11. (Fr., 9.8.21.)

Maynard. Vanning-table for concentrating gold, silver, tin, etc. 20,105. July 22.

N. V. Philips' Gloeilampenfabr. Manufacture of tungsten powder. 19,430. July 14. (Holland, 29.7.21.)

Rodriguez. Production of alloys. 19,054. July 11.

Complete Specifications Accepted.

64 (1921). Parr, Mawer, and Painton. Annealing and hardening high and low carbon steels etc. (182,825.) July 26.

9163 (1921). Goskar and Hitch. Composition for case-hardening iron and steel. (182,527.) July 19.

11,066 (1921). Chem. Fabr. Griesheim-Elektron, and Beielstein. Recovery of light metals from scrap. (182,948.) July 26.

1[illegible],129 (1921). Burgess. Reduction of aluminium oxide. (182,609.) July 19.

12,260 (1921). Usines Metallurgiques de la Basse-Loire. Production of basic steel. (163,693.) July 26.

13,235 (1921). Brunskill. Treatment to obviate rusting or oxidation of iron or steel surfaces. (182,988.) July 26.

19,474 (1921). British Thomson-Houston Co. (General Electric Co.). Manufacture of bodies of tungsten alloys. (182,699.) July 19.

XI.—ELECTRO-CHEMISTRY.

Applications.

Casale. Apparatus for electrolysis of water. 19,617. July 17.

David and Dutt. Primary batteries. 19,979. July 20.

David and Dutt. Storage batteries. 20,023. July 21.

F. I. A. T. Electric furnaces. 19,344. July 14. (Ital., 23.12.21.)

Felten u. Guilleaume Carlswerk. 19,739. *See* XIII.

Hansgirg. Electrolysis of zinciferous materials. 18,928. July 10.

Reichenstein. Stabilising detector and reinforcing effect of electrolytic cells. 19,581. July 17. (Ger., 19.7.21.)

Samuel. Electrical and thermal insulator. 19,174. July 12. (Fr., 1.8.21.)

Complete Specifications Accepted.

14,571 (1921). Heap, and Chloride Electrical Storage Co. Secondary batteries. (183,012.) July 26.

19,744 (1921). Hooker Electrochemical Co. Electrolysis of solutions. (167,469.) July 26.

1253 (1922). Frick. Electric-induction furnaces. (174,084.) July 19.

XII.—FATS; OILS; WAXES.

Applications.

Benson. Obtaining oil products. 19,039. July 11.

Zipser. Extraction of fatty etc. matters by means of volatile solvents. 20,059. July 21. (Austria, 27.7.21.)

Complete Specification Accepted.

9434 (1921). Webster. Treating the vapours and gases formed by heating fatty oils, gums, resins, etc. (182,869.) July 26.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Baggaley. Manufacture of invisible pencils, printers' and writing inks, etc. 19,803. July 19.

Felten u. Guilleaume Carlswerk. Protective covering for submarine cables. 19,739. July 18. (Ger., 18.7.21.)

Fletcher, West, and Titanine, Ltd. Manufacture of dopes, varnishes, or paints. 20,142. July 22.

Complete Specifications Accepted.

688 (1921). Plauson and Vielle. Manufacture of resins and oil-soluble dyestuffs. (182,497.) July 19.

9434 (1921). Webster. *See* XII.

10,214 (1921). Dehn (Satow). Manufacture of insoluble condensation products from phenol and formaldehyde. (182,886.) July 26.

18,949 (1921). Hetherington and Allsebrook. Manufacture of lead chromate pigments. (182,693.) July 19.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Barnes (Miller Rubber Co.). Manufacture of hard rubber articles. 19,071. July 12.

Barnes (Miller Rubber Co.). Manufacture of vulcanised rubber articles. 19,481–2. July 15.

Draemann. Manufacture of rubber filaments or threads. 19,744–5. July 18.

Naugatuck Chemical Co. Vulcanising rubber. 19,203. July 12. (U.S., 15.5.22.)

Complete Specifications Accepted.

1769 and 1782 (1921). Hopkinson. Treatment of rubber containing latex. (157,975 and 157,978.) July 19 and 26.

4950 (1922). Hug. Improving and regenerating indiarubber. (177,495.) July 26.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Ampt and Lansdown. Utilising cork, leather, etc. for manufacture of leather substitute. 19,015. July 11.

Complete Specifications Accepted.

54 (1921). Croad, Knowles, and McArthur and Co. Manufacture of tanning agents. (182,823.) July 26.

55 (1921). Croad, and McArthur and Co. Manufacture of tanning agents. (182,824.) July 26.

666 (1921). Chem. Fabr. Worms. Process for tanning hides. (156,670.) July 26.

1595 (1921). Reubig. Treating and finishing leathers. (157,864.) July 26.

XVI.—SOILS; FERTILISERS.

Application.

Kreiss. Phosphatic fertilisers. 19,747. July 18. (U.S. 13.9.21.)

Complete Specification Accepted.

15,694 (1921). Desmond and Tisdall. Fertilisers. (182,654.) July 19.

XVII.—SUGARS; STARCHES; GUMS.

Application.

Soc. Anon Etabl. Olier. Apparatus for extracting sugar from raw materials. 20,056. July 21. (Fr., 6.8.21.)

Complete Specifications Accepted.

1800 (1921). Campbell. Manufacture of starch. (182,829.) July 26.

7024 (1921). Corn Products Refining Co. Separation of gluten from starch. (159,838.) July 26.

7456 (1921). Mauss. Treatment of sugar juice. (182,855.) July 26.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Distillers Co., and Meyer. Treatment of yeast. 19,633. July 17.

Guthrie, and McEwan and Co. 19,069. *See* XIX.

Complete Specification Accepted.

2003 (1921). Wade (Schneible). Distilling alcoholic and other liquids. (182,832.) July 26.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Elektrizitätswerk Lonza. 19,703. *See* XX.

Guthrie, and McEwan and Co. Manufacture of food products from yeast. 19,069. July 12.

Jackson (Deuts. Ges. f. Schädlingsbekämpfung). Insecticides. 20,026. July 21.

Maclachlan Reduction Process Co. Treatment of sewage sludge. 19,185. July 12. (U.S., 12.4.22.)

Marks (Royal Baking Powder Co.). Effervescent mixtures. 19,048. July 11.

Morison. Degassing boiler feed water. 19,386. July 14.

Silver Springs Bleaching and Dyeing Co. Treating waste liquors. 20,000. July 21.

Complete Specifications Accepted.

7024 (1921). Corn Products Refining Co. *See* XVII.

10,603 (1921). Koppers Co. *See* III.

12,189 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Dissolving dried or concentrated milk. (182,612.) July 19.

XX.—ORGANIC SUBSTANCES; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Boehringer u. Söhne. Preparation of anthranilic acid derivatives. 19,511. July 15. (Ger., 20.7.21.)

Elektrizitätswerk Lonza, and Johnson. Production of metaldehyde and obtaining combustible substances therefrom. 19,703. July 18. (Ger., 9.3.22.)

Complete Specifications Accepted.

1627 (1921). Elektrochem. Werke, Bosshard, and Strauss. Production of sulphonated condensation products. (158,512.) July 26.

1628 (1921). Elektrochem. Werke, Bosshard, and Strauss. Production of a condensation product for naphthalene and glycollic acid. (171,956.) July 26.

13,004 (1921). Howards and Sons, Blagden, and Nierenstein. Manufacture of amino derivatives of hydrogenated cinchona alkaloids and their derivatives. (182,986.) July 26.

389 (1922). Lowe. Manufacture of saccharin. (174,913.) July 26.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Complete Specification Accepted.

7788 (1921). Kelley. Treating and dyeing photographic images. (160,137.) July 26.

XXII.—EXPLOSIVES; MATCHES.

Application.

Friederich and Rathsburg. Manufacture of priming compositions. 19,428. July 14. (Ger., 27.3.22.)

XXIII.—ANALYSIS.

Complete Specifications Accepted.

7162 (1921). König. Method and apparatus for measuring the density of gases. (159,845.) July 26.

I.—GENERAL; PLANT; MACHINERY.

Fractionating columns; Efficiency and capacity of ——. W. A. Peters, jun. J. Ind. Eng. Chem., 1922, 14, 476—479.

Using the definition given by Lewis of a theoretically perfect plate, the following formula showing the relation existing between the composition of the vapour rising from one plate, the liquid flowing back from the plate above, and the heat balance in the theoretical column is given, viz., $X_{n+1}=Y_n-Y_c(1-\rho)/\rho$, where X_{n+1} is the equivalent latent heat fraction of low boiling point material in the liquid on the (n+1)th plate; Y_n is the equivalent latent heat fraction of the low boiling point material vaporising from the *n*th plate; Y_c is the equivalent latent heat fraction of low boiling point material in the distillate; and ρ is the ratio of heat required to volatilise the reflux liquid divided by the total latent heat in vapour passing up through any horizontal cross section of the column. Knowing ρ, Y_n, and Y_c, X_{n+1} can be found, and thus the composition of the liquid and vapour at every point in the theoretical column can be fixed. In practice ρ, Y_n, and Y_c, are measured experimentally from columns working on known mixtures, and then the number of plates in a theoretical column which will give similar values is calculated. By dividing the calculated number of plates by the actual number of plates employed the efficiency factor, K, is found. With filled columns a measure of the efficiency can be obtained by dividing the calculated number of plates in the theoretical column by the height of the filled column in any chosen units. The reciprocal of this efficiency the author terms the height of the equivalent theoretical plates. Testing a sieve-type column, using a mixture of acetic acid and water, the author obtained values of K from 0·538 to 0·500, when ρ varied from 0·82 to 0·87, and found that for acetic acid and water mixtures in this type of column, with 1 in. of liquid on the plates, K is independent of ρ within the limits 0·8 to 1·0. Another series of tests was made on a Badger bubbler cap plate column, using alcohol and water mixtures, and it was found that with mixtures containing less than 90% by weight of alcohol K=0·70, but with mixtures richer in alcohol K had a smaller value. To determine whether the different values of K obtained from these two sets of experiments were due to the type of column, or to the difference in behaviour of the two mixtures, tests were made on a bubbler cap plate column using both mixtures under exactly similar conditions. The results indicated that there is no difference in the efficiency between plate columns of the sieve type and those of the bubbler type, provided that the immersion and diameter of perforations are comparable, but that there is a marked difference in efficiency of the same column for different mixtures. It is predicted that K will be less for materials of high molecular weight, and that for materials of equal molecular weight those mixtures in which there is less attraction between the unlike than between the like molecules will show a higher value of K. With packed columns it was found that the reciprocal of the efficiency varies nearly directly with the mean diameter of the filling pieces, and hence, to effect a given separation, columns may be of very short length when filled with very small pieces. The relative costs of the plate and filled columns are discussed, and it is concluded that with fillings 0·25 in. in diam., costing $30 per cubic foot, the filled column would be the cheaper.

—S. G. U.

Wood as a chemical engineering material. C. S. Robinson. J. Ind. Eng. Chem., 1922, 14, 607—610.

The advantages and disadvantages of chemical plant made of wood are discussed and the action of common chemicals on eleven usual kinds of wood given. The extent of the contamination of liquids with colouring matter from the wood is also given. The order of the popularity of woods for chemical work is as follows:—Cypress, yellow or hard pine, Californian redwood, white pine, Douglas fir, hard maple, yellow poplar, white oak, tamarack, spruce, Norway pine. The methods of construction of wooden tanks and pipes are illustrated.

—H. C. R.

Patents.

Filter presses. H. O. Traun's Forschungslaboratorium, Ges. m. b. H. E.P. (a) 155,834 and (b) 181,023, 24.12.20. Conv., 5.7.18.

(a) A filter press for working at pressures of 100 atm. or more consists of a cylinder fitted internally with three equidistant ribs to keep the filtering medium in position. The recesses thus formed act as passages for the filtrate, which is discharged through a valve mounted on the side of the cylinder at the lowest point. The filtering medium may be made of annuli of wire gauze, perforated cores wound round with wire of suitable thickness, or thin perforated concentric cylinders. The wire gauze annuli can be pressed together by screwing up the nut which forms the upper end of the containing cylinder. Inside the filtering medium revolves a worm, the lower end of which rotates in a boss formed in the base of the cylindrical casing. The upper end of the worm passes into another cylinder which is screwed into the nut forming the cover of the casing. On the top of this cylinder is a stuffing-box and gland through which passes the spindle for driving the worm. The material to be filtered is forced into the press through a valve mounted on the side of this worm cylinder. The liquid flows radially outwards through the filtering medium, and the worm forces the solid matter deposited on the inner surface of the filtering medium down to the base of the press and out through a valve mounted on the bottom of the containing cylinder directly in line with the worm. In another type of press the worm and filtering medium are housed in a telescopic casing. The worm at its lower end works inside a conical discharge pipe fitted in a flange through which pressure can be applied to the filtering medium. Special provision is made for taking up the end thrust in the worm shaft and to prevent leakage at the stuffing-box on the worm shaft. The outlet of this press is fitted with a plug valve held in position by a lever with weight or spring control to regulate the pressure of discharge. Sometimes a thin perforated metal cylinder is fitted in the press to prevent the nets or coils becoming too closely compressed and fouling the worm. (b) In a press of the type described above, to be used to filter colloidal precipitates, the coarser meshes of the filtering medium are filled with a permeable medium such as gypsum or cement paste. This is done by filtering a suspension of the substance, and, after the filter bed has been properly permeated, allowing the cement or the like to set before the filtration of the colloid is undertaken.—S. G. U.

Filters; Rotary ——. H. A. Valles. E.P. 181,879, 6.4.21.

In a non-continuous rotary vacuum filter, with a discharge channel for the filter-cake in the bottom of the casing, the outlet for the cake is midway of the length of the filter, and a worm conveyor leads thereto from each end. The filtrate is removed by means of a hollow shaft, which may also be used to admit pressure water or air for discharging, and which may work in conjunction with external sluicing jets. Means are provided whereby the thickness of the cake is shown on an indicator outside the casing.—B. M. V.

Evaporating apparatus. E. Barbet et Fils et Cie. E.P. 158,569, 27.1.21. Conv., 27.1.20.

The liquid is discharged from a tubular heater into a separator at a level not higher than the level of liquid maintained in the separator, and a pump receiving liquid from the separator delivers it to the heater. A diaphragm with a restricted orifice is arranged in the path of the liquid passing from the heater to the separator to secure a higher pressure in the heater than in the separator, thus ensuring superheating in the heater and vaporisation in the separator. A regulator is provided for maintaining a constant level of liquid in the heater and a valve for controlling the flow of liquid from the separator to the heater. The tubes may be closely arranged in the heater, a fan being used to increase the speed of circulation of the heating steam. Liquids readily deteriorated by heat, *e.g.*, milk, grape juice, gelatin, etc., are heated by circulation of hot water, which is heated by steam. For saline solutions the lower part of the separator in which the salts precipitate is conical.—H. H.

(A) *Evaporation; Method of ——.* (B) *Centrifugal separator and evaporator.* (C) *Process of treating liquid substances to change the condition thereof by evaporation.* (D) *and* (F) *Art of treating liquid substances.* (E) *Evaporating apparatus.* (G) *Apparatus for treating substances.* (H) *Multiple-effect apparatus.* (J) *Device for the evaporation of liquids and in the drying of substances.* (K) *Centrifugal dryer.* C. R. Mabee. U.S.P. 1,420,641—50, 27.6.22. Appl., (A) 18.2.19, (B) 31.8.12, (C) 23.12.12, (D) 24.10.13, (E) 9.12.13, (F) 19.7.15, (G) 12.2.16, (H) 23.10.15, (J) 15.12.13, (K) 15.12.13. Renewed (D) 12.7.16, (J) 18.3.20, and (K) 1.3.19.

The liquid to be evaporated, condensed, or dried to a powder, is spread circumferentially in a thin layer on the inside of a heated cylindrical container and at the same time moved from end to end either by slow speed spreaders or by centrifugal force. Either a portion or the whole of the container surface may be heated; in the former case the material is fed to the unheated portion, allowed to form the thin layer, and then passed to the heated portion. A large free space is left for vapours along the axis of the machine, and these are removed by a vacuum, or a fan, or merely by their own slight pressure. In the multiple-effect apparatus claimed in (H), the container has several compartments, the vapour from one section heating the next. The apparatus described in (J) has a vertical axis, the material being retained on the cylindrical walls by ridges or fins; in the other cases the axis of the apparatus is horizontal.

Crystallisation; Process of —— and apparatus therefor. Soc. Gén. d'Evaporation Proc. Prache et Bouillon. E.P. 159,815, 21.2.21. Conv., 5.3.20.

The solution is circulated between a reservoir and the tubes of an evaporator at such a speed that the crystals in suspension scratch the surfaces of the tubes and thus prevent the adhesion thereto of crystals in formation and remove any deposit formed. Crystals not circulated accumulate in the conical bottom of the reservoir.—H. H.

Filling columns, towers, etc., or the like through which gas is passed in an opposite direction to liquid; Bodies for ——. G. Petzel. E.P. (A) 160,180 and (B) 175,273, 16.3.21. Conv., 17.3.20.

(A) The packing is made by bending rectangular strips of sheet metal to form pieces having the shapes shown in cross-section in Fig. 1. The object of the invention is to provide a cheaply constructed filling having great contact area and which does not greatly reduce the passage-way. Perforated or non-perforated plates may be used in the construction of either type of packing. (B) The packing is made of any suitable material such as iron, porcelain, glass, terra-cotta, or unglazed brick, and is of the shapes shown in cross-section in Fig. 2. It is claimed that these packings provide a large number of baffling and contact surfaces which promote intimate contact between the gas and liquid.
—S. G. U.

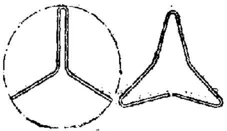

Fig. 1.

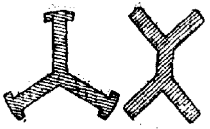

Fig. 2.

Waste heat; Utilisation of ——. Metallbank u. Metallurgische Ges. A.-G., and W. Gensecke. E.P. 181,787, 12.3.21.

The heat of waste steam, vapours, etc. from technical processes, such as drying processes or the chilling or granulating of hot slag in water, is used for generating steam. The heat is transferred by direct contact to a liquid medium, such as water, which is then separated from the waste steam, etc. and allowed partially to evaporate to generate steam for power or heating. The partial evaporation may be effected by injecting the liquid in a finely divided state into a vessel provided with an outlet for the steam generated. In the application to the chilling of slag, the water retained by the granulated slag may be continuously replaced by condensed water from a turbine or like plant. Drying apparatus may be heated by the waste steam from the high-pressure stage of a reaction engine of which the low-pressure stage is operated by the steam generated in the evaporator by the heat of the waste steam or vapour produced in the drying process.—H. H.

Mixing, reducing, or grinding and like machines. J. McIntyre. E.P. 181,877, 6.4.21.

A number of flexible blades are mounted on the rotating part of the machine so that their flat surfaces exert a rubbing action against the fixed outer part of the machine. Alternatively the blades may be fixed and the casing of the machine rotated.
—B. M. V.

Mixing machines. F. E. and G. H. Adams and T. D. M. Linkie. E.P. 181,920, 7.5.21.

Fixed blades co-operate with rotating blades within a container adapted to be tilted. The upper portion of the container is divided longitudinally into two parts, each hinged to the lower portion, and means are provided for retaining the two parts in the closed position.—H. H.

Disintegrators. J. K. Blum. E.P. 181,974, 20.6.21.

The aim of the invention is to provide a simple means of disintegrating the material, and separating particles of the desired fineness from the coarser particles. Disintegration is effected by means of a hammer cylinder rotating inside a

casing. The inlet and discharge openings of the machine are both situated in the top portion of the casing and on the same side of the vertical centre line of the machine. These openings are separated inside the casing by a breaker plate, which projects to a point in substantial proximity to the path of the rotor, thus preventing the short-circuiting of the air current between the intake and the discharge pipe. The under surface of this plate acts as the roof of the separating chamber, and is designed to give a swirling motion to the air discharged from the rotor before the air enters the discharge pipe. The rotor, by centrifugal action, throws the crushed material across the separating chamber in such a manner that it impinges on the breaker plate. The air currents are thus able to take up the fines in suspension and carry them away to the discharge pipe, whilst the coarse material drops back into the rotor chamber. The upper surface of the breaker plate is arranged so as to deliver the material fed to the machine tangentially to the rotor which also functions as a centrifugal blower. An auxiliary fan or blower may be used to provide a supplementary means of regulating the strength of the air current.
—S. G. U.

Crusher and pulveriser. M. F. Williams, Assr. to Williams' Patent Crusher and Pulveriser Co. U.S.P. 1,420,354, 20.6.22. Appl., 28.10.21.

The casing of the machine contains a series of segmental plates, each having a number of ridges, gradually diminishing in depth and parallel to the axis of the rotor. The bottoms of these ridges are rounded so as to form a continuous surface between the short face of one ridge and the long face of the ridge immediately above. The shorter face of each ridge is normal to the cylindrical surface swept out by the rotor arms at the point where its projection would intersect this surface. Provision is made for adjusting the distance between the rotor and the two upper segments, and the axis of the rotor is placed relatively to that of the casing, so as to provide a gradually diminishing space between the rotor and the plates. The machine is fed from the op, the feed hopper being placed on the side of he vertical centre line near the greatest opening between rotor and pates.—S. G. U.

Drying machine for coal or other granular material; Centrifugal ——. R. F. F. Fabry. E.P. 182,006, 23.7.21.

The machine consists of a conical shell, at or near the smaller end of which the material to be dried is continuously delivered by an inclined shoot. Fastened to the larger end of the shell, but separated from it by a continuous annular slit, is a short cylindrical extension. Sludge or water which has been removed escapes through this slit, while the dried material travels outward to the larger end and into a receiver. A jet of compressed air may be employed to prevent clogging of the slit by the granular material.—A. R. M.

Drying kiln. R. Thelen. U.S.P. 1,420,296, 20.6.22. Appl., 2.3.21.

A drying chamber is fitted with doors at either end and with a set of rails raised above the floor. The material to be dried is stacked on trucks which run on the rails. The drying medium is admitted at the base of the chamber near the exit end for the material, and is so baffled that it passes upwards through the material on the truck nearest the exit door, downwards through the material on the next truck, and so on until on rising through the material on the truck nearest the inlet door it is discharged by a fan placed on the roof of the chamber at the charging end. After every downward pass through the material the drying medium is reconditioned by suitable appliances mounted on the floor of the chamber.—S. G. U.

Dehydrating; Process and apparatus for ——. O. Q. Beckworth and O. J. Hobson, Assrs. to Anhydrous Food Products Co. U.S.P. 1,420,679, 27.6.22. Appl., 27.1.19.

The plant consists of two chambers placed back to back and suitably fitted internally to hold the articles to be dried. Along the back wall of each chamber is a radiator to supply radiant heat to the articles in the chamber. The front walls of each chamber are hollow and contain radiators to condition the medium, which is circulated through the chamber. In starting the process a vapour of high density and temperature enters the apparatus at the bottom, and passing upwards and across the goods to be dried, leaves the chamber through a valve placed in the roof. This medium is used to warm and moisten the goods, and suitable valves and piping are provided whereby this medium can be reheated and returned to the chamber. When the warming and moistening of the goods is completed this medium can be drawn off and replaced by a less dense medium, also at a high temperature, which can also be circulated through the reconditioner and chamber. Means are provided for circulating vapour and air through the chamber and for cooling the goods after dehydration has been completed.—S. G. U.

Drying machine. G. Stone, Assr. to M. T. Stevens and Sons Co. U.S.P. 1,421,856, 4.7.22. Appl., 15.12.21.

Superposed horizontal rows of conveying rollers conduct the material in a sinuous course through the machine, the rollers of each row being separated by air spaces. Heated air is delivered beneath each row through independent conduits, and is exhausted and discharged upwards through the spaces between the rollers, thus serving both to dry and to lift the material in transit on the rolls.—H. H.

Air, gas, or vapour; Apparatus for purifying ——. P. Graefe. E.P. 182,201, 29.3.21.

The gas or air under treatment is passed between a series of parallel units which are built up as follows:—Each unit consists of two parallel plates, namely, the back plate and the scale plate, which are joined together round the edges to form a narrow chamber. This chamber is sub-divided into a number of parallel chambers by distance strips or similar contrivances, which slope at such an angle that any liquid or dust immediately slides down and is deposited at the bottom of the unit. The scale plate of each unit has a series of openings round which are scales or wedge-shaped projections which are placed in rows and so arranged that the gas flowing from one row will impinge on the projections of the next row at right angles to the projecting surfaces. Any foreign matter travelling with the gas is thus deposited on the projections, and falls therefrom into the space between the plates and so to the bottom of the unit. In forming a plant the units may be placed with the back plate of No. 2 unit touching the scale tips of No. 1 unit; or with the tips of the scales of No. 2 unit touching the scale plate of No. 1 unit and the tips of the scales of No. 1 unit touching the scale plate of No. 2 and the back plate of No. 2 touching the back plate of No. 3 unit; or with the tips of the scales of No. 1 touching the tips of the scales of No. 2 and the back plate of No. 2 touching the back plate of No. 3 unit. The gas after passing through the spaces between the units is discharged into a separate chamber from that connected with the spaces between the plates forming the units. Plants can be designed for working with either a horizontal or vertical gas flow.—S. G. U.

Removing suspended matter from gases; Apparatus for ——. J. P. Fisher, Assr. to Doherty Research Co. U.S.P. 1,420,986, 27.6.22. Appl., 29.8.19.

The gases pass from end to end of a separating chamber fitted near the inlet with a fan adapted to throw material centrifugally to the walls of the chamber, and near the outlet with a second fan adapted to create a smaller centrifugal effect than the inlet fan. The outlet fan is arranged to cause gases to pass directly through it to the outlet. The length of the chamber is made substantially greater than the combined width of the fans in order to enable the suspended matter to settle out of the gases whilst they are passing from one fan to the other.—H. H.

Removing a liquid from the surface of molten metal; Method of ——. Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and J. S. Morgan. E.P. 182,302, 7.6.21.

In the distillation of liquids or similar processes of heat treatment by means of a bath of molten metal, the residual liquid is removed from the surface of the molten metal, *e.g.*, lead, by means of a disc or drum dipping into the metal and a scraper which removes the liquid from the drum. The drum or disc has a surface of non-metallic material, preferably silica.—B. M. V.

Catalyser and method of producing the same. W. D. Richardson, Assr. to Swift and Co. U.S.P. 1,419,986, 20.6.22. Appl., 9.3.20.

A catalyst is produced by abrading a suitable metal in the presence of water.—B. M. V.

Volatilising, distilling, or separating absorbed vapours; Method of ——. C. L. Voress and V. C. Canter, Assrs. to Gasoline Recovery Corp. U.S.P. 1,420,613, 20.6.22. Appl., 9.12.21.

Vapour mixtures are recovered or removed from gas mixtures by absorption in a solid absorbent, from which they are subsequently distilled by heated distillation vapours. The distillation vapours are passed into intimate contact with the charged absorbent for a time sufficient only to volatilise the major portion of the absorbed vapours, and substantially denuded gas is then passed through the absorbent for the displacement of condensed products from the distillation vapours.—H. H.

Roasting, calcining, etc. materials containing oxygen or carbon dioxide; Process of ——. A. Helfenstein. G.P. 352,241, 24.4.21.

The material, previously dried as far as possible, and reduced to a finely granular or powdered condition, is fed downwards in a thin layer along the heated walls of a shaft furnace, the material collecting at the bottom of the shaft being then raised to a higher temperature, and, if desired, sintered, by heat radiated from the walls of the shaft. The material collecting at the bottom of the shaft may also be submitted to the action of a gaseous cooling medium, which is subsequently employed to preheat or dry the material to be roasted. The shaft tapers from the top downwards for about two-thirds of its length and then becomes wider again. It is closed at the lower end by hollow crushing rollers in which a gaseous cooling medium circulates.
—J. S. G. T.

Air or other gaseous mixtures; Process of recovering constituents of ——. R. Wucherer and F. Pollitzer, Assrs. to The Linde Air Products Co. U.S.P. 1,420,802, 27.6.22. Appl., 24.8.17.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Gases; Ignition of —— by sudden compression. H. T. Tizard and D. R. Pye. Phil. Mag., 1922, 44, 79—121.

The tendency to detonation in internal combustion engines is closely related to the delay which occurs in the ignition of mixtures of combustible gases and air by compression. This delay in ignition is dependent on (1) the compression temperature, (2) the temperature coefficient of the reaction, and (3) the rate of loss of heat to the walls. The relationships among these three factors have been examined theoretically and experimentally for mixtures of heptane, ether, and carbon bisulphide with air. The apparatus designed by Ricardo was employed in the experimental work. The rise in absolute temperature which is necessary to treble the reaction velocity is 4% in the case of carbon bisulphide and 7% in the case of ether and heptane. This is in agreement with the relative tendencies of these substances to detonate in an interna combustion engine. Carbon bisulphide has muc less tendency to detonate than heptane, althoug its ignition temperature is considerably lower. Th rate of reaction on sudden compression appear within wide limits to be independent of the con centration of the combustible gas, and depends onl on the amount of oxygen present. The effect o turbulence is studied.—W. E. G.

Carburettor adjustments by gas analysis. A. C Fieldner and G. W. Jones. J. Ind. Eng. Chem 1922, 14, 594—600.

The proportion of carbon dioxide in the exhau gases bears a direct relationship to the com pleteness of combustion and the air-fuel rati

The air-fuel ratio for motor spirit as used at the present time, for maximum power at full load, extends from about 11:1 to 15:1. The relative mileage which may be obtained from a given quantity of fuel is measured by its thermal efficiency. Maximum thermal efficiency is obtained at an air:fuel ratio of 16·5 to 17·5:1. Power must be sacrificed to some degree to secure the greatest mileage. The relation of the air-fuel ratio to the percentage of carbon dioxide in the exhaust gases is shown by a curve obtained from laboratory tests, and another obtained from road tests on 101 different motor vehicles using different brands of spirit agrees closely with it. To adjust a carburettor by gas analysis, tests should be made on the road under the different conditions under which the machine is to be driven. The machine is run until thoroughly warmed up and then tested at a given speed on the level by taking samples of the exhaust gases and analysing for carbon dioxide content. The air-fuel ratio can then be read off from the curve given. Should the percentage of carbon dioxide be low the carburettor is given a slightly "leaner" adjustment and again tested, and a record kept of the carbon dioxide content and carburettor adjustment for each test. When the highest carbon dioxide percentage consistent with flexible working has been obtained, the machine is tested at other speeds. Then, by plotting the carbon dioxide percentages at the different speeds, the carburettor setting giving the highest average carbon dioxide percentage at the different speeds, and also flexible working, should be chosen as the best adjustment. A carbon dioxide indicator for adjusting carburettors on the road is described and illustrated. Two min. is required to sample and analyse the gas. The indicator is accurate to 0·2% with carbon dioxide contents of 14%. Tables are given showing the gain in mileage which can be obtained by proper carburettor adjustment.

Petroleum; Surface tension of ——. C. K. Francis and H. T. Bennett. J. Ind. Eng. Chem., 1922, **14**, 626—628.

THE surface tension of petroleum from various parts of the United States was determined, and was found to increase with the specific gravity. The small quantity of fatty acids and wax commonly found in petroleum products does not appear to influence the surface tension. The presence of high-boiling fractions and products of high viscosity tends to raise the surface tension of the lighter petroleum products. The surface tension decreases with rise in temperature by about 0·05 dyne per sq. cm. per 1° F. The connexion between viscosity and surface tension appears to be very slight, as an increase in Saybolt viscosity from 51 to 1160 is only accompanied by an increase in surface tension from 34·4 to 37·3.—H. C. R.

Coking chambers for gas generators. Bismarckhütte. E.P. 163,012, 6.5.21. Conv., 6.5.20.

A COKING chamber for use in conjunction with a gas producer is provided with a horizontal plate, spaced below the open end of the chamber so as to provide a peripheral discharge opening for the coked material, and forming a support for the material being coked. At the top of the chamber there is a concentric rotary feed hopper into which coal is continuously fed from bunkers and from which it passes into the chamber through openings at the lower end. The hopper extends downwards into the chamber so as to form an annular gas-collecting space, into which dust cannot readily pass, at the top of the chamber. Attached to the bottom of the hopper there is a vertical shaft carrying a stirrer and an ejector spaced just above the horizontal plate.—H. Hg.

Vertical [*gas*] *retorts.* F. J. Collin, A.-G. zur Verwertung von Brennstoffen und Metallen. E.P. 165,744, 30.6.21. Conv., 2.7.20.

A PERFORATED pipe is laid in a channel cut in the base of the wall of a vertical retort provided with a water-seal, and is used alternatively for supplying water to the seal and steam to the retort for the generation of water-gas.—H. Hg.

[*Gas*] *retorts.* Low Temperature Carbonisation, Ltd., and T. M. Davidson. E.P. 181,894, 18.4.21.

VERTICAL retorts suitable for low-temperature carbonisation are constructed of cast iron or other metal, and the inner and outer surfaces are protected by firebrick slabs. The retorts are provided with external horizontal and internal vertical ribs of a dovetail shape in order to secure the slabs to the retort surfaces.—H. Hg.

[*Coal*] *gas; Method of and apparatus for manufacturing* ——. A. F. Kersting, Assr. to L. C. Hamlink. U.S.P. 1,420,041, 20.6.22. Appl., 2.5.19.

A NUMBER of retorts are charged in sequence with coal and, by means of suitable gas connexions between the retorts, the gas from a freshly charged retort is, during the earlier stage of carbonisation, passed through a retort containing more completely carbonised coal to an off-take.—H. Hg.

Gas producers [*; Stirrer and fuel-feeding device for* ——]. Dowson and Mason Gas Plant Co., Ltd., and E. Wilson. E.P. 182,053, 19.11.21.

IN a producer of the type provided with mechanical stirrers and automatic fuel feed, horizontal arms are supported in such a manner as to be capable of rocking on their axes. Fingers or stirrers depend from the arms and sink into the fuel to an extent regulated by the resistance offered by the fuel bed. Varying leverage may be exerted on the arms by means of weighted box-castings on the ends of the arms, and the depth of the fingers in the fuel bed thus varied. Each arm with its depending fingers may be made to act independently so far as its oscillatory movement is concerned. Means are provided for obtaining relative rotary movement between the fuel bed and the oscillating stirrer arms, and for providing water cooling for the latter and the depending fingers. The drive and means for feeding and distributing the coal are controlled from the stirrer arms, which, by acting as the spokes of a wheel, may transmit the drive from a circumferential rack. The coal or other fuel is fed from a revolving drum into a continuously revolving spreader and thence distributed evenly over the area of the producer, both the drum and the spreader working in unison from the same drive.—A. R. M.

Petroleum oils; Still for fractionally distilling ——. E. C. R. Marks. From Shell Co. E.P. 182,247, 20.4.21.

The still is particularly designed for the re-fractionation of gasoline-kerosene fractions. The fraction is heated by means of the hot residues from which it was originally distilled. A long horizontal still is divided by vertical partitions and heated by tubes through which the residuum flows. The gasoline-kerosene fractions flow along this still and steam is admitted into each portion. Each section is provided with its own vapour exit.—T. A. S.

A mixture of a petroleum distillate, an alcohol, and an aromatic hydrocarbon is blended with a phenol. —A. G.

Fuel for internal combustion engines. M. C. Whitaker, Assr. to U.S. Industrial Alcohol Co. U.S.P. (A) 1,420,006 and (B) 1,420,007, 20.6.22. Appl., 12.11.19.

The fuel is composed of (A) a light hydrocarbon, an alcohol, a diethyl ketone, and an ester, or (B) 35—50% of an alcohol, 25—35% of an aromatic hydrocarbon, and 20—40% of an ester.—A. G.

Oils; Process for cracking ——. R. D. George. U.S.P. 1,420,832, 27.6.22. Appl., 14.9.21.

The process consists in heating to cracking temperature heavy hydrocarbon oils in continuous flow through an upright still. The heated oil is delivered from the top of the still to a separating chamber wherein is maintained a pool of hot oil above the level of the still. In the separator the volatile portions are removed and condensed. The residual oil is freed from carbon in a separator and returned to the bottom of the still. The amount of free carbon in the cleaned oil is kept below 1%.—T. A. S.

Oil-bearing shale; Apparatus for treating ——. G. A. Heimbucher. U.S.P. 1,421,228, 27.6.22. Appl., 3.9.18.

An apparatus for treating oil-bearing shale consists of a furnace, in which several vertical retorts are arranged above a combustion chamber; a wall having helical flues surrounds the lower end of each retort, and is spaced from the outer wall of the furnace, and segmental walls meeting at their ends, and spaced from the outer wall of the furnace, partly surround the upper portion of each of the retorts, the space enclosed by these segmental walls forming a heating chamber, connected with the combustion chamber by the helical flues, and also with a chimney stack. Each retort may be fitted with a mechanically operated rotating grate and with a tapered perforated pipe, which projects upwards from the centre of each grate. Outside each pipe is a device for agitating the shale in the retort when the grate is rotated.—A. B. S.

Hydrocarbon oils; Treatment of ——. D. T. Day. U.S.P. 1,422,038, 4.7.22. Appl., 17.6.19.

Hydrocarbon oils of low boiling point are produced from those of high boiling point by vaporising part of the oil to be treated and compressing the vapour immediately in a cylinder by means of a piston, which moves "substantially instantaneously" to generate sufficient heat and pressure to convert the vapour into the desired product. —A. B. S.

Coal; Method of cleaning ——. *Process of purifying materials;* [*coal*]. W. E. Trent, Assr. to Trent Process Corp. U.S.P. 1,420,163 and 1,420,165, 20.6.22. Appl., 9.7.19 and 25.2.20.

IV.—COLOURING MATTERS AND DYES.

2.3.2′.3′-*Naphthindigo.* H. E. Fierz and R. Tobler. Helv. Chim. Acta, 1922, 5, 557—560.

The conversion of 2.3-hydroxynaphthoic acid into 2.3-aminonaphthoic acid is effected by heating with ammonium chloride and ammoniacal zinc chloride in a current of ammonia at 180°—190° C. for 36 hours. The yield is 68—70% when zinc chloride of good quality is used, and the unchanged 2.3-hydroxynaphthoic acid can be recovered. The presence of zinc oxychloride causes side reactions with the formation of β-naphthylamine and dinaphthacridone. Condensation of the 2.3-aminonaphthoic acid with chloroacetic acid is quantitative, with the formation of 2.3-naphthylglycinecarboxylic acid, crystallising from alcohol in yellow needles, m.p. 240° C. The conversion of the glycine into 2.3.2′.3′-naphthindigo gives very poor yields by any of the usual methods. The pure dye crystallises from nitrobenzene in nearly black tablets. It dyes greenish-blue shades from the hydrosulphite vat; the brominated dye is green. The dye takes up three atoms of bromine, but is not thereby rendered fast to chlorine. The shade is purer than that of Ciba Green G, however, and it is equally fast to light. —E. H. R.

peri-*Naphthindigo; Attempts to prepare* —— *and the behaviour of azo dyes from naphthylglycines.* H. E. Fierz and R. Sallmann. Helv. Chim. Acta, 1922, 5, 560—566.

Attempts to prepare peri-naphthindigo from 1.8-naphthylglycinecarboxylic acid failed, owing to the unstable character of the naphthylglycine. The maximum yield of naphthostyril obtained by oxidation of naphthalimide with sodium hypochlorite was 50%. By condensing naphthostyril with chloroacetic acid, naphthostyrylacetic acid, m.p. 256° C., was obtained, which, by boiling with sodium ethoxide, gave disodium 1.8-naphthylglycinecarboxylate, a white powder. The following naphthylglycinesulphonic acids were prepared by condensing the corresponding naphthylaminesulphonic acids with chloroacetic acid:—1.8-acid, colourless needles containing $1H_2O$; 1.4-acid, yellow crystals with $1H_2O$, having a strong blue fluorescence in alkaline solution; 1.5-acid, anhydrous colourless leaflets or needles, with green fluorescence in alkaline solution; 2.1-acid, colourless fan-shaped needle aggregates, with $2H_2O$. The azo dyes from all these naphthylglycinesulphonic acids are decomposed by boiling water. Azo dyes were made by coupling diazobenzene and *p*-nitrodiazobenzene with β-naphthylglycine ethyl ester; the m.ps. were 135° and 156° C. (decomp.) respectively. The latter dye, when decomposed with boiling acetic acid, gave as identifiable products αβ-naphthyl-(*p*-nitrophenyl)-dihydrotriazinecarboxylic ester, naphthimidazole, and *p*-nitraniline. (*Cf.* J.C.S., Sept.)—E. H. R.

Patents.

Acridine dyestuffs; Manufacture of new halogen derivatives of basic ——. Durand & Huguenin A.-G. E.P. 165,721, 14.6.21. Appl., 30.6.20.

Halogenated dyestuffs containing several halogen atoms in the molecule are obtained by direct treatment of basic acridine dyestuffs or their leuco-derivatives with halogen, or with an agent capable of liberating halogen. These products will dye red-orange to pure red shades on leather and on tannin-mordanted cotton, and can also be applied to dyeing natural or artificial silk. They are fast against the action of chlorine. *Example:* 20 pts. of Acridine Orange sulphate and 36 pts. of sodium bromide are slowly stirred into 400 pts. of concentrated sulphuric acid at 0° C. After some hours the temperature is slowly raised to 50° C. until a sample dissolves in water with a vivid red colour. The product is then poured on to ice, salted out, filtered, washed with brine, and dried at 60° C. The substance is a dibromo-derivative, and dyes pure red shades on tannin-mordanted cotton.—G. F. M.

Soluble acid colouring matters; Manufacture of a new series of —— *and of intermediate compounds for the manufacture thereof.* A. G. Green, K. H. Saunders, and British Dyestuffs Corp., Ltd. E.P. 181,750, 18.12.20 and 16.8.21.

A new series of dyestuffs of the benzene and naphthalene series is described which dye wool and silk from an acid bath, and which owe their solubility and acid character to the presence of an alcoholic sulphuric acid group, $-CH_2.O.SO_3H$, attached to nitrogen. This $-SO_4H$ group is termed a sulphato group, and it may be introduced in a variety of ways either into the structure of dyestuffs or into their intermediates. For example, an N-oxyalkyl derivative may be prepared from either an intermediate or a dyestuff by the action of ethylenechlorohydrin, and this, on treatment with concentrated sulphuric acid, or fuming sulphuric acid, chlorosulphonic acid, etc., under such conditions as would normally convert ethyl alcohol into the hydrogen sulphate, yields the sulphato compound. Another method consists in reacting in neutral or alkaline solution with chloroethyl hydrogen sulphate, prepared by dissolving ethylenechlorohydrin in sulphuric acid, on a dyestuff or its component or intermediate, containing a primary or secondary amino group. In this way the ethyl sulphato group is introduced at one step. The method is not limited to the ethyl group, as propylene, butylene, or glycerol chlorohydrins may be used in the same way as ethylenechlorohydrin. A large number of examples are given of the preparation ofsulphato acids of intermediates and of azo dyestuffs, triarylmethane dyestuffs, and of oxazine, azine, and thiazine colouring matters of the benzene and naphthalene series.—G. F. M.

Colouring matters [hydroxyethyl, hydroxypropyl, etc. derivatives of oxazine, azine, and thiazine dyestuffs]; Manufacture of ——. British Dyestuffs Corp., Ltd., A. G. Green, K. H. Saunders, and E. B. Adams. E.P. 182,031, 30.8.21.

Dyestuffs possessing a quinoneimide structure, and containing one or more hydroxyalkyl groups attached to nitrogen, are obtained by applying the standard reactions for the preparation of oxazines, azines, or thiazines to intermediates containing such hydroxyalkyl groups. Thus oxazine dyestuffs are obtained by condensing a nitroso derivative of a hydroxyalkylarylamine with a phenolic compound. For example, violet to blue dyestuffs of the gallocyanine type are obtained by using gallic acid, gallamide, etc. in the above reaction. If a nitroso derivative of a *m*-hydroxyoxyalkylarylamine is condensed with an alkylarylamine or an oxyalkylarylamine, oxazine dyestuffs are also produced, whilst if the arylamine is naphthylamine or its derivatives blue dyestuffs of the Nile Blue type, but of greatly increased solubility are obtained. Oxyalkylthiazine dyestuffs are produced by converting a nitroso derivative of an oxyalkylarylamine into the corresponding *p*-diaminethiosulphonic acid by treatment with thiosulphate, or by converting a *p*-nitroso-alkylarylamine into the *p*-diaminethiosulphonic acid, and oxidising this together with an oxyalkylarylamine. In the preparation of azine dyestuffs a nitroso derivative of an oxyalkylarylamine may be condensed with an oxyalkyl- or other N-substituted *m*-diamine, or a nitroso-derivative of an alkylarylamine may be condensed with an oxyalkyl-*m*-diamine. In each case the intermediate indamine is converted into the azine in the usual way. Azine dyestuffs of this class may also be obtained by the oxidation of a mixture of a *p*-diamine with two arylamines, one of which is primary, whilst oxyalkyl groups may replace one or more hydrogen atoms in the amino groups of the second arylamine or of the *p*-diamine. Lastly, the oxyalkyl group may be introduced into oxazine dyestuffs, particularly those of the gallocyanine type, by subsequent condensation with components such as oxyalkyldiamines which contain this group attached to one nitrogen, whilst the other amino group is unsubstituted.—G. F. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

[Wool] fleece of the Blackface lamb; Micrological study of the ——. F. A. E. Crew and J. S. S. Blyth. J. Text. Inst., 1922, **13**, 149—156.

In the examination of the fleeces of Blackface lambs which were either still-born or had died shortly after birth, three types of fibres were found. One, in its proximal portion, had the characters of typical hair, at its tip the characters of typical wool, and the middle portion had a structure intermediate between hair and wool. The second type of fibre had the structure of wool near its tip, but its proximal portion resembled the middle portion of the first type. The third type of fibre resembled wool from root to tip. Those fibres which resembled wool constituted more than half of the fleece and compared very favourably with wool of recognised commercial value.—A. J. H.

Wool; Sorption of neutral soap by —— *and its bearing on scouring and milling processes.* British Research Assoc. for the Woollen and Worsted Ind. J. Text. Inst., 1922, **13**, 127—142.

The wool used in the experiments was purified by scouring it with potash-olive oil soap and sodium carbonate, and afterwards extracting it three times with absolute alcohol. The soap was prepared from sodium carbonate and pure oleic acid and was afterwards purified by extraction with hot alcohol; it finally contained a slight excess of fatty acid. The wool was immersed in a soap solution for a definite time at a definite temperature and the loss of alkali and fatty acid by the soap solution was then determined. The alkali portion of soap is sorbed much more than the fatty acid, so that the soap solution becomes charged with an excess of fatty acid. The loss of fatty acid by the soap solution is due to sorption of actual soap and to precipitation on the wool fibre of some of the fatty acid liberated as the result of the preferential sorption of caustic soda. In the case of dilute solutions, this precipitation is the main cause of the loss of fatty acid by the solution. This precipitaton of fatty acid decreases with increase of concentration of the soap solution owing to the "protective colloid" action of the soap, so that with strong solutions the loss of fatty acid is chiefly due to sorption of actual soap. The sorption of soap by wool proceeds for several hours without sign of equilibrium, and is greatly accelerated by rise of temperature. During the initial stages of the contact between wool and a soap solution the rate of loss of alkali is very much greater than the rate of loss of fatty acid, but this difference lessens with time, and after prolonged contact the two rates become roughly equal. With mixtures of soaps of oleic and palmitic acids there is a preferential sorption of the oleic acid by wool, but potassium and sodium oleates do not differ essentially with respect to the absorption of either alkali or fatty acid. The sorption of alkali by wool from a chemically neutral soap solution is equal to that from a solution of caustic alkali of very much smaller concentration, and this suggests a method of measuring the "effective alkalinity" of neutral soaps and other salts such as sodium carbonate and borax which are alkaline in aqueous solution. Comparison of the alkali absorption by wool from caustic soda solutions and from soap solutions under identical conditions showed that the ratio of the concentration of caustic soda to that of the soap solution giving equal sorption, increases with increase of dilution. In the treatment of wool with alkaline soap liquors, the known advantage of having free alkali (carbonate) present may be due to its physical action in increasing emulsification, and also to its action in opposing the liberation of fatty acid. In soap-milling processes it is probable that the alkali of the soap is the real milling agent and that the liberated fatty acid exerts only secondary functions in controlling the extent of the sorption of caustic soda from the soap, in preserving the handle of the wool, and in acting as a lubricant.—A. J. H.

Wool; Standard method for the estimation of soap in ——. British Research Assoc. for the Woollen Worsted Ind. J. Text. Inst., 1922, **13**, 143—149.

The sample of wool is extracted twelve times (this is usually sufficient) with absolute alcohol in a Soxhlet extractor lagged with asbestos tape or cord and having ground-in joints (corks are not satisfactory). The hot solution is then filtered through thin Swedish filter paper No. 1 F, the bulk of the alcohol is evaporated, the residue is evaporated to dryness in a wide-necked glass flask on a water-bath, and is afterwards dried first in a water oven and then to constant weight *in vacuo*. The dried residue is boiled with a known excess of *N*/10

sulphuric acid, allowed to cool, shaken out three times with neutral ether, and the ethereal layer then separated and washed with water, the washings being added to the aqueous layer. The residue containing total oil and fatty acid, obtained by evaporating the ethereal extract, is dissolved in absolute alcohol and titrated with $N/10$ caustic soda or potash and phenolphthalein, whereby the fatty acid content is determined. The soap is determined by back titration of the aqueous extract with $N/10$ caustic potash, the difference between the acid originally added and that remaining being calculated to sodium oleate. This method of back titration is necessary, since the whole of the soap is decomposed only on boiling with excess of acid. The calcium soaps extracted may be determined by estimating calcium by the usual methods in the above aqueous extract, which has been titrated for soap. It frequently happens that a persistent emulsion forms when shaking out with ether, and it is then advisable to separate as much ether as possible, evaporate the acid liquor to dryness, and wash the residue with ether to remove fatty acid or oil. The amount of fatty matter in such an emulsion may amount to 0·03% on the weight of the wool. Although alcohol is a satisfactory solvent for soap, it is not possible to recover from wool the same amount of soap as is placed in it, since there is distinct evidence that some of the alkali of the soap combines with or becomes absorbed by the wool substance itself, leaving free fatty acid on the fibre. Atmospheric carbon dioxide is able to decompose soap into an "acid soap" and an alkali carbonate, and this affects the process of analysis.
—A. J. H.

Lignin of fir wood; Constitution of the ——. P. Klason. Svensk Kem. Tidskr., 1922, 34, 4—17. Chem. Zentr., 1922, 93, III., 55—56.

The calcium salt of α-ligninsulphonic acid was prepared by treating sulphite-cellulose waste liquors with calcium chloride. Waste liquor was also precipitated in three separate fractions with sodium chloride and the β-naphthylamine salts were prepared from the three fractions and from the residual liquor. All these preparations were substantially identical, corresponding with the formula $C_{20}H_{20}O_6+H_2SO_3+C_{10}H_7NH_2$; hence it is inferred that α-ligninsulphonic acid is a uniform substance. β-Naphthylamine salts have been prepared from several derivatives of the calcium α-ligninsulphonate, *e.g.*, from compounds with hydroxylamine, semicarbazide and ammonia, also from the product of acetylation with acetic anhydride at 50°—100° C. for twelve days. α-Naphthylamine salts of the α-lignosulphonic acid itself, of its methylated derivative, and of the carboxylic acid formed by oxidation with hydrogen peroxide at the ordinary temperature for forty-five days are also described. It is concluded that α-lignin is a definite uniform substance containing a coniferyl aldehyde nucleus, the presence of which throws light on the chemistry of the bisulphite process; it also contains a flavone or coumarone ring, whereby it is related to the catechins, flavones, etc. but differs from them in that it is characterised by an acrolein complex which is combined like an acetal with the carbohydrates of the wood.—J. F. B.

Patents.

Textile and other fabrics, thread, yarn, and the like; Process of treating —— [to remove starches, gums, and other impurities]. J. Takamine and J. Takamine, jun. U.S.P. 1,421,613, 4.7.22. Appl., 8.10.20.

Textiles, threads, yarns and the like are treated in a bath containing proteolytic and diastatic enzymes, to dissolve and remove starchy matter, gums, and other impurities, and are then washed with water.—D. J. N.

[Nitrocellulose composition;] Compound sheet material [from ——]. Manufacture of waterproof material. C. Claessen. E.P. (A) 174,317, 8.7.21, and (B) 174,588, 12.1.22. Conv., 21.1.21, 28.1.21. Addns. to 155,778 (J., 1922, 459 A).

(A) A compound sheet material resembling wax cloth is made by interposing a supporting fabric between two thin skins of the nitrocellulose composition described in the original patent, and uniting the three layers by pressing or rolling. (B) A strong waterproof material, suitable for packing joints, for chair seats and other purposes, is made by cementing together, by heat and pressure, alternate layers of the nitrocellulose composition and fibrous materials such as vulcanised fibre, cardboard, or paper, and allowing the mass to cool under pressure.—D. J. N.

Artificial silk and the like; Manufacture of ——. W. P. Dreaper. E.P. 181,758, 19.1.21.

Skeins of artificial silk, during the final drying process, are supported in a drying chamber in such a manner that they occupy the major portion of the cross-section of the chamber, and a blast of heated air, travelling at the rate of 3—5 m. per sec., is driven along the chamber through the skeins to keep the individual filaments in relative movement to one another during the drying process, the arrangement of the skeins being such that entanglement is prevented. This method of drying prevents the cohesion of the filaments and gives a bulky thread of high covering power.—J. F. B.

Cellulose [viscose]; Manufacture of threads, filaments, strips or films of ——. Courtaulds, Ltd., and M. T. Callimachi. E.P. 181,900, 23.4.21.

Starch is dried at a moderate temperature, preferably under reduced pressure, until it contains not more than 5% of moisture. 58 pts. of the dried starch is added rapidly, with continuous stirring, to 100 pts. of 62% sulphuric acid cooled below 0° C. When a homogeneous paste is obtained the mixture is allowed to warm up spontaneously, whilst the starch goes into solution. The resulting liquid is diluted with 540 pts. of water, and is used for the preparation of acid saline coagulating baths for the spinning of viscose threads etc.—J. F. B.

Cellulose [viscose]; Manufacture of threads, filaments and the like of ——. Courtaulds, Ltd., and H. J. Hegan. E.P. 181,901, 23.4.21.

The tendency for filaments to break at the jet orifice during spinning is counteracted by the addition to the viscose of a substance capable of lowering the surface tension of the viscose relatively to the coagulating bath. For viscose prepared from cotton the addition of 2 pts. of sodium oleate per 10,000 pts. of viscose is suitable.—J. F. B.

Cellulose [viscose]; Manufacture of coloured threads, filament strips or films of ——. Courtaulds, Ltd., and L. J. Wilson (legal representative of L. P. Wilson). E.P. 181,902, 23.4.21.

Coloured filaments etc. are produced from viscose by incorporating with the viscose a leuco-compound of a vat or sulphur dyestuff, and spinning and coagulating the coloured viscose in the usual manner. The alkaline solution of the dyestuff, reduced by sodium hydrosulphite, is either added directly to the viscose or is mixed with the caustic soda solution employed for dissolving the cellulose xanthate.—J. F. B.

Cellulose derivatives; Manufacture of artificial silk and the like from ——. H. Dreyfus. E.P. 182,166, 21.3.21.

In spinning artificial silk by the dry method of projecting solutions of cellulose esters or the like in volatile organic solvents into heated air, the rate of solidification is controlled by the addition of limited quantities of solvents of high boiling point to the cellulose solution, thereby enabling it to be drawn down to extremely fine filaments before solidification. For example: 100 pts. of cellulose acetate is dissolved in 400 pts. of acetone, and 25—50 pts. of diacetonealcohol (b.p. 163°—165° C.) is added to control solidification. Other suitable solvents of high boiling point are: acetonealcohol (acetylcarbinol), acetylacetone, cyclopentanone.—J. F. B.

Cellulose ester products [*and artificial silk of standardised dyeing speed*]; *Method of preparing* ——. H. S. Mork and O. F. Coffin, jun., Assrs. to The Lustron Co. U.S.P. (A) 1,421,288, (B) 1,421,289, and (C) 1,421,290, 27.6.22. Appl., (A) 12.3.21, (B, C) 16.11.21.

Cellulose ester products of standardised dyeing speed are made by: (A) blending together in presence of a solvent such quantities of several previously prepared batches of ester as will give a homogeneous product having the desired dyeing speed; or (B) equalising the dyeing speeds of a number of batches of the ester by suitably treating those batches which have the slower dyeing speed, and subsequently uniting all the batches in a solvent. (C) Several lots of artificial silk are prepared, and their dyeing speeds are substantially equalised by suitably treating those lots which show the slower dyeing speed.—D. J. N.

Paper product and process of making the same. E. G. Acheson. U.S.P. 1,419,951, 20.6.22. Appl., 15.7.20.

In a process of making filled papers, a step consists in incorporating with the pulp a filling material in a deflocculated state.—L. A. C.

Paper; Method of removing ink from printed ——. H. R. Eyrich and J. A. Schreiber, Assrs. to The Paper De-Inking Co. U.S.P. 1,421,195, 27.6.22. Appl., 27.4.21.

Ink is removed from paper by applying an alkaline solution of bentonite.—A. B. S.

Cotton substitutes; Manufacture of ——. B. Possanner von Ehrenthal. E.P. 156,709, 7.1.21. Conv., 7.8.19.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Modified steam oven [*for lecture experiments on steaming of cotton fabrics*]. A. G. Perkin. J. Soc. Dyers and Col., 1922, 38, 186—187.

An adaptation of the ordinary laboratory water oven suitable for the development of colour on cotton fabrics by steaming in lecture experiments. A short upright pipe terminating in a funnel-shaped opening for the purpose of charging the oven with water and having a tap fixed just below the funnel, is fixed to the usual steam exit. To this tube at a point just below the tap is connected another metal pipe which also has a tap and which is led into the interior of the oven through the usual central thermometer opening which is closed with a perforated cap. A small tube having a tap is connected to the steam jacket of the oven and serves as a safety device. The oven can thus be used in the usual manner or the steam generated in the jacket can be directed into the interior of the oven and escape through the perforated cap. The door of the oven may be provided with a jacket filled with asbestos powder so that the steam within the oven remains dry. A hollow saddle through which hot water circulates and on which fabrics may be dried is also attached to the water jacket of the oven. The oven is provided with hinged supports. —A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid concentration; Thermal considerations in ——. F. C. Zeisberg. Chem. and Met. Eng., 1922, 27, 22—26.

The data available as to the specific heat, boiling point, partial pressure, heat of dilution, and heat of vaporisation of solutions of sulphuric acid in water are summarised. When a solution of sulphuric acid has been raised to its boiling point the heat necessary to carry on concentration is the sum of the heat of vaporisation of water (added to that of sulphuric acid if the latter is not negligible), the heat of dehydration (equivalent to the heat of dilution), and the heat necessary to maintain ebullition or the summation of the increments of heat necessary to raise the temperature of the acid to new and continually higher boiling points. These quantities are calculated and shown graphically. The curve of the total heat necessary is almost a straight line from 65% to 98% H_2SO_4 and over this range there is less than 2% error in assuming that 23·3 B.Th.U is required per lb. of H_2SO_4 per 1% difference. From these curves the thermal efficiencies of concentrators can be calculated, that of the Gilchrist surface evaporator (J., 1922, 585 A) on the data given, being 86·3%.—C. I.

Sulphur trioxide; Physical properties of ——. A. Berthoud. Helv. Chim. Acta, 1922, 5, 513—532.

Sulphur trioxide is supposed to exist in two solid modifications, α and β. Experiments show that the silky form, β, is probably a hydrated form; it owes its formation to the presence of water, but cannot contain more than 1 mol. of water per 1000 mols. of sulphur trioxide. The following constants of sulphur trioxide were measured with the greatest care: m.p. 16·85° C.; b.p. 44·52° C. (760 mm.); critical temp., 218·3° C.; critical pressure, 83·8 atm.; critical density, 0·633; molecular heat of vaporisation, 10,300 cals.; van der Waals' constants, $a = 0{\cdot}01629$, $b = 0{\cdot}002684$. (*Cf.* J.C.S., Sept.) —E. H. R.

***Hydrofluoric acid; Apparatus of transparent bakelite for measuring* ——.** L. J. Curtman. J. Ind. Eng. Chem., 1922, 14, 610.

Hydrofluoric acid (48%) is without appreciable action on transparent bakelite, and 10 c.c. graduated vessels made from this material have been successfully used in analytical work. They were made slightly conical in shape to facilitate pouring from the wax containers. They are less brittle than glass, non-inflammable, do not soften or become distorted, and can be readily cleaned with hot water. A medicine dropper of the same material can be used with advantage in testing for silica. —H. C. R.

[*Ammonium nitrate; Preparation of* ——]. *The equilibrium of double decomposition between soluble salts and some of its applications. II.* E. Rengade. Chim. et Ind., 1922, 7, 1090—1098.

The preparation of ammonium nitrate by double decomposition between sodium nitrate and ammonium chloride is not possible by methods similar to those by which potassium nitrate is obtained, as ammonium nitrate is at all temperatures the most soluble of the salts in equilibrium. The amount of nitrate and ammonium ions, expressed arbitrarily as ammonium nitrate left in the solution, after the crystallisation of sodium chloride, is 63·6% of the total salts at 80° C., and 81% at 108° C. From this mixture it is possible to obtain only small quantities of pure ammonium nitrate by extraction of the sodium chloride with cold water, *e.g.*, 9·7% at 0° C., and the process is therefore useless technically. The principal points of the equilibrium diagram of the system at 20° C. were determined. The double decomposition between sodium nitrate and ammonium sulphate in presence of alcohol gave more promising results, and in fact, if the mixed salts, containing an excess of sodium nitrate just sufficient always to maintain some of this salt in the solid phase, are treated with alcohol the decomposition will be complete. The excess of nitrate required will be equal to the amount dissolving in the alcohol. To prevent the formation of two layers the alcoholic strength must be at least 97% at the boiling temperature, or 78% if the operation is conducted at ordinary temperatures (25° C.). It is therefore preferable to work at 25° C., and a rapid equilibrium is attained by the following procedure: Sufficient 92% alcohol and water to make 360 pts. of 78% alcohol are taken, 102·5 pts. of sodium nitrate is dissolved in the water, with the aid of heat, 66 pts. of ammonium sulphate added, and then the 92% alcohol, and the whole is allowed to cool. The solution strained off from the insoluble sodium sulphate contains 22·2% of ammonium nitrate and 4·8% of sodium nitrate. The alcohol is recovered and rectified up to 92% for re-use, and the crude salt is freed from sodium salts by extraction with 6·7 parts of cold water for every 4·8 parts of sodium nitrate it contains. This will also dissolve 11·0 pts. of ammonium nitrate, leaving a net yield of pure salt of 51%. The solution is returned to the process, and the total yield is therefore 100% theoretically.—G. F. M.

Ammonium chloride; Preparation of —— *at low temperatures.* P. Mondain-Monval. Comptes rend., 1922, 175, 162—164.

The conditions governing the crystallisation of ammonium chloride, at 0° C., from solutions containing in addition one or more of the salts, sodium chloride, sodium carbonate, and ammonium carbonate, were studied in a similar manner to that previously described for 15° C. (J., 1922, 369 A), and a Le Chatelier diagram is given showing the surfaces of saturation. The zone of crystallisation of sodium carbonate shows two distinct areas, one corresponding to the crystallisation of $Na_2CO_3,10H_2O$, and the other to that of a hydrate of the formula, $2Na_2CO_3,5H_2O$, the existence of which, although disputed by Wegscheider (J., 1912, 69), is now confirmed.—G. F. M.

Aluminium nitride; Heat of formation of ——. F. Fichter and E. Jenny. Helv. Chim. Acta, 1922, 5, 448—454.

Aluminium nitride prepared from aluminium bronze contained about 91% AlN and 0·5% Si, the remainder being alumina. The heat of combustion as measured in a bomb calorimeter, the nitride being mixed with a proportion of benzoic acid to facilitate combustion, was

$$2AlN+3O=Al_2O_3+N_2+258{\cdot}2 \text{ Cals.}$$

Subtracting this from $2Al+3O=Al_2O_3+380{\cdot}2$ Cals. the heat of formation of aluminium nitride is $Al+N=AlN+61{\cdot}0$ Cals. If the silicon present in the nitride is in the elementary form, a correction is necessary and the final result is 62·7 Cals. —E. H. R.

Boron nitride; Reaction between —— *and various metallic oxides with production of nitric oxide.* U. Sborgi and A. G. Nasini. Gazz. Chim. Ital., 1922, 52, I., 369—387.

Measurements have been made of the yields of nitric oxide obtained when air is passed over mixtures of boron nitride with various metallic oxides heated at different temperatures. The highest yields of nitric oxide were obtained with ferric oxide (66·57—71·86% of the theoretical quantity, at 850°—970° C.), nickel oxide, Ni_2O_3 63·66—65·86%, at 800°—880° C.), cobalt oxide, Co_2O_3 (60·26—72·08%, at 820°—920° C.), manganese dioxide (59·88—71·60%, at 800°—840° C.), and manganese oxide, Mn_3O_4 (50·85—71·72%, at 700°—790° C.). The residue, after the reaction, contains a considerable proportion of the oxide uncombined and can be used for decomposing further quantities of boron nitride. The reactivity of the boron nitride diminishes on keeping; the above results were obtained with a nitride (85·84% BN) prepared from boron trioxide and ammonia at about 1100° C., and preserved *in vacuo*.—T. H. P.

Sodium sulphide; Analysis of commercial ——. *Committee on limeyard control. V.* W. R. Atkin. J. Soc. Leather Trades' Chem., 1922, 6, 239—243.

8—10 g. of the sample is dissolved in distilled water to make 1 litre, and 50 c.c. of the solution titrated in a comparator to $p_H=10$, using phenolphthalein or thymolphthalein as indicator. 10 c.c. of neutral formaldehyde is added and the mixture titrated with $N/10$ hydrochloric acid to neutrality. The second titration measures the amount of sulphide. 1 c.c. $N/10$ HCl=0·0078 g. of Na_2S.—D. W.

Reagents free from arsenic; Preparation of ——. G. Lockemann. Z. angew. Chem., 1922, 35, 357—360.

The preparation of arsenic-free reagents for, *e.g.*, determinations of small traces of arsenic for toxicological purposes may be conveniently divided into three groups: (1) neutral salts, alkalis and ammonia, (2) acids, and (3) hydrogen. The purification of reagents comprised in the first class is based on the adsorption of arsenic by freshly-precipitated ferric hydroxide, prepared as follows:—Ferric ammonium sulphate is freed from arsenic by repeated crystallisation and the purified salt is dissolved in water to a concentration of 225 g.p.l. (corresponding to 50 g.p.l. of ferric hydroxide or 1·404 N); the freedom from arsenic of this solution is checked by testing 20 c.c., acidified with 20% sulphuric acid, in a Marsh's apparatus.

The ammonia solution used for precipitation of the ferric hydroxide is prepared by diluting 240 c.c. of a 10% solution of ammonia to 1 litre, and adjusting its strength, by titration, until equivalent in normality to the iron solution; a portion is tested, after acidification, in a Marsh's apparatus, and the solution freed from arsenic, if present, by treatment with freshly-precipitated ferric hydroxide. For this purpose 100 c.c. of the ammonia solution is mixed with 100 c.c. of the purified ferric ammonium sulphate solution, and after stirring well, the ferric hydroxide is filtered off, washed with cold water, transferred to a litre flask, shaken up with the bulk of the ammonia solution to be purified, the residue allowed to subside and the supernatant layer, after its freedom from arsenic has been ascertained, adjusted to the before-mentioned strength. The two solutions described are employed for freeing from arsensic, all neutral water-soluble reagents which do not react with either iron or ammonia. For this purpose the reagent in question is dissolved to about a litre volume of solution not quite saturated at 0° C., cooled with ice, and 10 c.c. of iron solution added. 3 c.c. of the ammonia solution is next added, and the mixture stirred, allowed to stand for 15 mins., treated with a further 7 c.c. of ammonia solution to precipitate the iron completely, allowed to stand for 4 hrs., and filtered. The author claims a more complete adsorption by such fractional precipitation. 10 c.c. of the iron solution corresponds to 0·5 g. of $Fe(OH)_3$, and this quantity is sufficient to remove the following quantities of arsenic from a litre of solution: at 0° C. 40 mg., 20° C. 30 mg., 40° C. about 15 mg., and 80° C. about 9 mg. The accompanying adsorption of non-arsenical salts must be taken into consideration when calculating the quantity of iron adsorbent necessary for purification. The effectiveness of the adsorption of arsenic and the quantity adsorbed are tested by thoroughly washing the ferric hydroxide precipitate with cold water until free from the reagent originally to be purified, dissolving in 4*N* sulphuric acid and testing in a Marsh's apparatus. By a second trial adsorption of the purified solution with 3 c.c. of iron solution and 1+2 c.c. of ammonia solution, and testing of the precipitate, the completeness of the first adsorption is determined. The ammonium sulphate formed as a secondary product of the ferric hydroxide precipitation may be removed by recrystallisation, or its presence avoided by adsorbing the arsenic on to previously precipitated ferric hydroxide, but owing to the lower efficiency in such cases a much larger amount, *e.g.*, 10—25 g., of ferric hydroxide per litre must be employed. Arsenic-free nitric and hydrochloric acids are prepared by the interaction of arsenic-free sulphuric acid and alkali nitrate and chloride respectively, freed from arsenic by the treatment with ferric hydroxide already described. Arsenic-free sulphuric acid is prepared by leading a current of hydrochloric and hydrobromic acid gases, obtained by the action of sulphuric acid on a solution of 3 g. of potassium bromide in 10 c.c. of water to which has been added 50 g. of potassium chloride, through 600 c.c. of sulphuric acid maintained at 150° C., the reduced and volatilised arsenious chloride being distilled over and the last traces removed by raising the temperature of the sulphuric acid to 200° C. and displacing the arsenious chloride by carbon dioxide. Any accompanying sulphurous acid must be removed by subsequently oxidising with potassium permanganate and distilling in a porcelain retort. The original paper contains details of the apparatus and its manipulation by which it is claimed that 600 c.c. of acid may be freed from arsenic in 2¼ hrs. Arsenic-free hydrogen is most conveniently generated by the action of arsenic-free hydrochloric acid on an alloy consisting of 9 pts. of zinc to 1 pt. of copper, which retains the whole of the arsenic, unlike zinc of low copper content (0·1—0·2%), which evolves its arsenic along with the hydrogen.—A. de W.

Arsenic and antimony; Volatilisation of —— by methyl alcohol. L. Duparc and L. Ramadier. Helv. Chim. Acta, 1922, 5, 552—556.

By passing a current of air through a solution of arsenious or antimonious oxide in concentrated hydrochloric acid containing a suitable proportion of methyl alcohol, the whole of the arsenic can be carried over into an absorbing solution. In this way 0·1 g. of As_2O_3 dissolved in concentrated hydrochloric acid can be volatilised in 1 hr. at 55° C. after addition of 45 c.c. of methyl alcohol saturated with dry hydrogen chloride. In the case of Sb_2O_3 not more than 59% can be volatilised under similar conditions, and volatilisation can be entirely prevented by diluting the hydrochloric acid with an equal volume of water. The method may be applicable for separating arsenic and antimony from other metals or from each other.—E. H. R.

Positive rays; Analysis by —— of the heavier constituents of the atmosphere, of the gases in a vessel in which radium chloride had been stored for 13 *years, and of gases given off by deflagrated metals.* J. J. Thomson. Proc. Roy. Soc., 1922, **A 101**, 290—299.

The residues from many thousands of tons of liquid air have been examined by the positive ray method of analysis for the presence of molecules heavier than krypton and xenon. Two new constituents of the atmosphere were found with molecular weights 163 and 260. The lighter of these is the more abundant, but the quantity in the air is very small compared with xenon. No place in the periodic table can be found for a new element with atomic weight 163, and it is possible that the two new substances are diatomic molecules of krypton and xenon. The gases from radium stored in an evacuated vessel for about 13 years, showed the presence of helium and hydrogen, but no xenon nor H_3 was found. Evidence was obtained of the existence of a compound of hydrogen and helium. The gases from the deflagration of fine wires of tungsten, gold, or copper by powerful electric currents did not yield any helium, although H_3 was detected. In gases which had stood over radium for a considerable time the presence of doubly, triply and quadruply charged atoms of oxygen and nitrogen, and doubly and triply charged carbon atoms was indicated by the positive ray method of analysis. A compound OH_2, carrying a double charge, was also noted.—W. E. G.

Urea from ammonia. Matignon and Fréjacques. *See* XX.

PATENTS.

Sulphuric acid manufacture; Recovery of oxides of nitrogen in ——. A. M. Fairlie. U.S.P. 1,420,477, 20.6.22. Appl., 19.5.20.

The normal quantity of sulphur dioxide contained in the exit gases is removed, the lower nitrogen oxides are oxidised to higher oxides, and these are absorbed.—H. R. D.

Sulphur burner. A. G. Hinzke. U.S.P. 1,421,232, 27.6.22. Appl., 17.6.21.

A sulphur burner comprises a shell, on the top of which is a melting vessel, with feed supply orifices and valve-controlled means for regulating the flow of molten sulphur into the shell; a central duct extends through the melting vessel and shell, and has a discharge pipe at its upper end. Means are provided for causing the molten sulphur to follow a serpentine course to the lower end of the central duct, up which the resulting hot gases pass.

—A. B. S.

[Sludge] acids; Method of treating ——. I. Hechenbleikner and T. C. Oliver, Assrs. to Chemical Construction Co. U.S.P. 1,421,688, 4.7.22. Appl., 16.6.21.

Sludge acid is concentrated in two stages, the first being checked before the charring point is reached. —C. I.

(A) *Hydrochloric acid and carbon monoxide; Process of manufacturing* ——. (B) *Apparatus for use in effecting chemical reactions.* (C) *Apparatus for effecting chemical reactions [by means of amalgams].* (D) *Method of and apparatus for electrolytic reduction and oxidation.* (E) *Manufacture of [metal] oxalate.* H. W. Paulus, Assr. to Royal Baking Powder Co. U.S.P. 1,420,209—13, 20.6.22. Appl., (A) 19.7.20, (B—E) 26.7.20.

(A) A mixture of hydrochloric acid and carbon monoxide is prepared by passing a mixture of chlorine and steam in the correct proportions through an incandescent mass of carbon contained in a vessel sealed from the atmosphere, sufficient air being introduced with the mixed gases to maintain the carbon at the temperature necessary to effect the desired chemical reactions. (B) An apparatus for use in effecting chemical reactions comprises a horizontal, jacketed, cylindrical drum provided with a shaft supported in jacketed heads at the ends of the drum. Spiders are mounted on the shaft at each end of the drum, and adjustable scrapers, supported in staggered relation from the spiders, are provided to keep the interior surface of the drum clean. A relatively large inlet is provided for admitting gases into the drum, while waste gases are withdrawn through a number of relatively small outlets. Means are also provided for heating or cooling the drum, to maintain the contents at a desired temperature. (C) An apparatus for effecting chemical reactions by means of amalgams comprises an electrolytic cell in which the amalgam is formed, a reaction chamber, and a cooling trough between the cell and the chamber. The electrolytic cell is divided into a series of longitudinal channels to facilitate the passage of mercury through the apparatus, while the bottom of the cooling trough is provided with a series of transverse depressions for the same purpose. The reaction chamber is divided into a series of channels, some of which receive mercury from the trough, while the mercury in others passes back to the cell, the mercury in the channels being impelled in one or the other direction by two sets of paddles. Means are provided for returning the mercury from the chamber to the cell. (D) An apparatus for electrolytic reduction and oxidation comprises a cell for containing the electrolyte, a stationary plate electrode in the cell, and means for imparting a rotary motion, relative to the surface of the electrode, to the electrolyte admitted to the cell. (E) Metal oxalates are prepared by dropping finely divided, dry metal formates into a descending stream of inert gases maintained at 360°—440° C.—L. A. C.

Halogen compounds [hydrochloric acid and methyl chloride]; Preparation of ——. W. O. Snelling. U.S.P. 1,421,733, 4.7.22. Appl., 4.6.20.

Methane and chlorine are allowed to interact, and the gas mixture scrubbed successively with solvents for methyl chloride and for hydrogen chloride. —C. I.

Hydrogen and ammonia; Preparation of ——. The Nitrogen Corp., Assees. of J. C. Clancy. E.P. 163,323, 17.5.21. Conv. 14.5.20.

Sulphur vapour is subjected to direct contact with superheated steam, at about 800° C., in a refractory tube furnace. The exit gases, consisting chiefly of sulphur dioxide, hydrogen, and excess of steam, may be separated in various ways. Hydrogen may be used for the synthesis of ammonia, and the latter used for absorbing the sulphur dioxide, whereby ammonium sulphite is formed and can be oxidised to ammonium sulphate.—H. R. D.

Ammonia; Oxidation of ——. *Catalyst. Manufacture of sulphuric acid.* (A) C. H. MacDowell, H. H. Meyers, and W. B. Pattison, (B, C) C. H. MacDowell and H. H. Meyers, Assrs. to Armour Fertiliser Works. U.S.P. (A) 1,420,201, (B) 1,420,203, and (C) 1,420,202, 20.6.22. Appl., (A) 3.12.18, (B, C) 20.1.19.

(A) A mixture of ammonia and an oxidising gas is brought, at a high temperature, in contact with a composite catalyst composed of vanadium oxide and porous alumina made from alunite. (B) A composite catalyst comprises a compound of vanadium and a compound of aluminium in which each compound contributes to the catalytic activity. (C) A mixture of gases containing sulphur dioxide and oxygen, at a temperature suitable for the catalytic production of sulphur trioxide, is brought in contact with the composite catalyst described in (B).—L. A. C.

Sulphate of ammonia; Manufacture of dry neutral ——. Ebbw Vale Steel, Iron and Coal Co., Ltd., and D. Thickins. E.P. 181,884, 9.4.21.

The process of neutralisation and drying is carried out in a form of tower by an ascending current of hot air and ammonia gas. The tower is provided with a central rotating shaft fitted in the upper part with brush arms which sweep the salt across sieves, and in the lower part with scrapers which work over slotted or perforated plates. The exit gases are passed into an absorbent for pyridine. —C. I.

Aluminium chloride; Method of manufacturing ——. Aluminium Co. of America, Assees. of F. C. Frary. E.P. 163,975, 30.12.20. Conv., 26.5.20.

See U.S.P. 1,354,818 of 1920; J., 1920, 749 A. A mixture of alumina and metallic aluminium may be used in place of aluminium dross.

Titanium dioxide from bauxite; Process for preparation of ——. E. E. and P. C. Dutt. E.P. 181,775, 18.2.21.

One pt. of finely powdered bauxite (containing 7—10% TiO_2) is mixed with 5 pts. of ammonium sulphate, and the mixture heated to about 350°—400° C. After the reaction is complete, the product is treated with water. The double sulphates of alumina and iron with ammonia pass into solution, whilst titanium dioxide remains in the liquid in the form of a very fine suspension, which can be decanted off from any residue. The titanium dioxide is then separated by filtration, washed, and dried.—H. R. D.

Sulphur, metallic sulphides and the like; Recovery of —— *from a condition of emulsion without filtration or evaporation.* B. Hunt. E.P. 181,984, 16.3.22.

An emulsion of sulphur and gangue in water is heated above the melting point of sulphur in an autoclave, with agitation. The earthy matter remains in suspension, while liquid sulphur may be run off from the bottom. Certain metallic sulphides if mixed with sulphur and treated as above are removed with the molten sulphur.—C. I.

Sodium carbonate; Separation of ——, *from liquors or solutions containing caustic soda.* Courtaulds, Ltd., and R. O. Jones. E.P. 182,411, 11.6.21.

100 pts. of liquor containing about 19% of caustic soda and 7% of sodium carbonate, is treated at 20°—30° C., with 10 pts. of finely divided calcium

carbonate, and allowed to stand, stirring at intervals, whereupon the double carbonate of calcium and sodium is precipitated.—H. R. D.

Sodium carbonate and the like; Process of purifying ——. F. H. Merrill. U.S.P. 1,419,463, 13.6.22. Appl., 30.4.21.

SODIUM carbonate is freed from carbonaceous matter by heating with sodium nitrate.—J. B. F.

Sodium carbonate from common salt; Electrolytic process of manufacture of ——, *employing a diaphragm cell.* Chem. Fabrik Griesheim-Elektron. G.P. 352,002, 19.8.19.

A SOLUTION of potassium bicarbonate, potassium chloride, and sodium chloride is used in the cathode compartment of the cell and is electrolysed until the bicarbonate is neutralised. The supply of sodium chloride is then replenished and the solution treated with carbon dioxide.—J. S. G. T.

Vanadium solutions; Process of removing phosphorus from ——. A. N. Erickson, Assr. to Union Carbide and Carbon Research Laboratories, Inc. U.S.P. 1,421,191, 27.6.22. Appl., 5.10.21.

PHOSPHORUS is removed from vanadium solutions by adjusting the hydrogen ion concentration to about that of very dilute acetic acid, and then precipitating the phosphorus as phosphate.—A. B. S.

Bleaching powder. E. T. Ladd and E. C. Speiden, Assrs. to Isco Chemical Co., Inc. U.S.P. 1,421,503, 4.7.22. Appl., 7.2.22.

THE claim is for screened chlorinated calcium hydroxide, from which a substantial proportion of the smaller sized particles has been removed before chlorination.—H. R. D.

Alumina; Process of obtaining ——. R. S. Sherwin, Assr. to Aluminium Co. of America. U.S.P. 1,422,004, 4.7.22. Appl., 16.1.14. Renewed 3.4.19.

A SINTERED unfused alumina-silica-lime-soda mixture is heated with an alkaline solution of a sodium compound to a temperature not above 200° F. (93° C.) preparatory to leaching.—H. R. D.

Arsenic trichloride; Process of making ——. L. H. Milligan, Assr. to N. D. Baker. U.S.P. 1,421,978, 4.7.22. Appl., 12.6.20.

A PROCESS of making arsenic trichloride comprises heating an arsenic compound with chlorine and a reducing agent.—H. S. H.

Lead oxide; Apparatus for production of —— *by oxidising molten lead.* L. Kübler. G.P. 351,328, 16.11.20.

THE molten lead is contained in a large tall vessel preferably provided with a heat-insulating jacket. Two oppositely directed pipes for admission of compressed air are provided in the lower part of the vessel, and another similar pipe below a perforated false floor in the vessel.—J. S. G. T.

Colloidal iron solution having a neutral or feebly alkaline reaction; Production of ——. H. Timpe. G.P. 351,384, 23.12.20.

A VERY dilute solution of a ferric salt is added in equivalent proportion to a solution of an alkaline pyrophosphate of definite strength. The ferric pyrophosphate produced is filtered off, purified, mixed with water, and treated with the equivalent quantity of a solution of an alkali carbonate; a protective colloid may be added to the resulting colloidal solution.—J. S. G. T.

Continuous process of lixivating salts, more especially crude potassium salts. Fellner u. Ziegler, and M. König. G.P. 351,533, 26.7.19.

THE material is supplied to a casing in which it is mixed with leaching fluid by stirring gear rotating within the casing and provided with heating tubes. The material is carried through the upper layers of the leaching fluid on lifts disposed on the circumference of the stirring gear and then falls back into the trough of the apparatus. Adjustable sliding plates are disposed along the circumferential walls of the stirring chamber, and may be inclined so that material falling upon them from the walls of the chamber moves either in a forward or backward direction, and the transportation of the material through the apparatus is thus either accelerated or retarded.—J. S. G. T.

Sodium sulphide, sodium bisulphate, etc.; Process of atomising fused masses of ——. V. Zieren. G.P. 351,581, 11.3.19.

THE fused mass is atomised and simultaneously cooled by currents of air impinging at an angle so as to produce turbulence. For example, three air streams, one incident upon the fused mass from below, the others impinging upon the sides, may be used.—J. S. G. T.

Sulphate; Manufacture of —— *by the Hargreaves process.* F. Siemens. G.P. 352,115, 20.3.20. Addn. to 339,818.

IN a process carried out in accordance with G.P. 339,818 (J., 1921, 813 A), sulphur compounds, such as kieserite or sulphur ores, are mixed with the charge. When reduced substances decomposed with difficulty, *e.g.*, calcium sulphide, are formed, they are decomposed with carbon dioxide, acid, or steam, and made available for further use. Oxy-salts, such as gypsum, which are difficult to decompose, are mixed prior to the briquetting process, with easily decomposed chlorine compounds, *e.g.*, waste lyes from the potash industry. Coal rich in sulphur may be used for the purpose of recovering their sulphur in the form of sulphates by the Hargreaves process.—J. S. G. T.

Calcium bisulphite lye and sulphur; Process for the simultaneous production of ——. Rhenania Verein Chem. Fabr. A.-G., Zweigniederlassung Mannheim. G.P. 352,126, 11.6.20.

CALCIUM sulphide is added to a solution of calcium bisulphite into which sulphur dioxide is passed. Alternatively, a concentrated aqueous solution of sulphur dioxide into which sulphur dioxide is constantly passed is treated with calcium sulphide. —J. S. G. T.

Graphite; Process of producing ——. T. F. Baily. U.S.P. 1,420,512, 20.6.22. Appl., 31.1.22.

A BATH of superheated molten iron is saturated with carbon, and poured into a closed cooling chamber wherein it is cooled sufficiently to cause the separation of the surplus carbon in the form of graphite. —H. R. D.

Air; Liquefaction of ——. H. N. Davis, Assr. to Research Corp. U.S.P. 1,420,625, 27.6.22. Appl., 24.4.20.

IN a process for effecting heat exchange in the liquefaction of air, one gaseous stream flows in counter-current heat-exchanging relation with a second colder gaseous stream, and in order to equalise, as far as possible, the effective heat-transferring capacities of the two streams, a portion of the gas is withdrawn from the warmer stream, cooled, and then returned to counter-current heat-exchanging relation with the colder stream at a point colder than its point of withdrawal.—H. H.

Sulphur; Contact furnace for producing —— from hydrogen sulphide or gases containing it. Rhenania Verein Chem. Fabr. A.-G., and F. Projahn. G.P. 352,178, 18.10.18. Addn. to 298,844.

In a process operated in accordance with the earlier patent (J., 1920, 749 A) the gas is supplied through a number of nozzles, and a number of tubes closed below to serve as pockets for thermometers are arranged in the furnace between the door and the grate. The furnace is suitable for carrying out the Claus process.—J. S. G. T.

Ammonia; Synthesis of ——. Nitrogen Corp., Assees. of J. C. Clancy. E.P. 155,592, 20.12.20. Conv., 20.12.19.

See U.S.P. 1,363,392 of 1920; J., 1921, 469 A.

Chromic oxide and sodium sulphide; Process for the manufacture of —— from sodium chromate. C. J. Head. U.S.P. 1,422,703, 11.7.22. Appl., 14.1.21.

See E.P. 166,289 of 1920; J., 1921, 623 A.

Electrochemical reactions. E.P. 181,848–9. *See* XI.

VIII.—GLASS; CERAMICS.

Lamination [in clay]; Discussion of cause and cure of ——. J. J. F. Brand. J. Amer. Ceram. Soc., 1922, 5, 355—375.

Laminations are divided into two classes, viz., differential lamination caused by the differential flow of the clay through the die etc., and interfacial lamination due to the imperfect union of formed masses of clay. Neither the character of the clays studied nor the kind of machines used accounted for the difficulties attending the moulding and drying of the clay wares. The effect of pugging and of working upon the character of the clays was studied, and it is concluded that the presence of air in the clay caused the difficulties in moulding. It is suggested that the air should be removed from the clays prior to and during the tempering and pugging process.—H. S. H.

Clay briquettes; Simplified method of determining the dry volume of ——. J. L. Crawford. J. Amer. Ceram. Soc., 1922, 5, 394—396.

The dry volume of a clay briquette is obtained by dividing its dry weight by its bulk specific gravity, determined on a separate test-piece. This method eliminates the drying of oil-saturated test-pieces when determining the change of volume of a clay briquette after various heat treatments.—H. S. H.

Ceramic products; Firing —— in electrically heated furnaces. A. Granger. Comptes rend., 1922, 175, 98—100.

A comparison of the different types of porcelain obtained by firing in electrically heated furnaces as compared with the same materials fired in industrial furnaces. The results with the electrically heated furnaces are quite satisfactory, and it is shown that the reducing action in furnaces may be due to carbon in the form of carbon monoxide, which is oxidised to carbon dioxide and deposits carbon, and not necessarily to flames too rich in carbon.—W. G.

Terra-cotta; Firecracking of ——. E. C. Hill. J. Amer. Ceram. Soc., 1922, 5, 299—310.

Large pieces of terra-cotta made from various clays and grogs were fired and cooled at different rates. The absorption, porosity, and transverse strength of the various bodies were determined and their tendency to firecrack after weathering was noted. All bodies similar to those used in practice showed a tendency to firecrack when cooled rapidly and all were free from cracks when cooled slowly, the rate of cooling having a much greater effect on the tendency to firecrack than the composition or physical properties of the body. Owing to the difference in the expansion of sand and clay, sandy clays were more liable to produce firecracks than non-sandy, vitrifying clays. The tendency of a body to develop firecracks depended much more upon the character of the clay itself, regardless of the impurities it contained, than upon the absorption, porosity, or transverse strength of the body. No relation was found to exist between the porosity and transverse strength of a body and its tendency to firecrack. The greatest tendency to firecracking was found in a body with all the grog finer than 40-mesh, but a body with all the grog coarser than 40-mesh did not appear to have much less tendency to firecrack. Increase of grog reduced the tendency to firecrack. The kind of grog used had less effect on the tendency to firecrack than the size and the amount, the kind of grog being of much less importance than the kind of clay used.—H. S. H.

Porcelain; Tensile strength of ——. F. H. Riddle and J. S. Laird. J. Amer. Ceram. Soc., 1922, 5, 385—393.

The tensile strength of porcelain test-pieces was determined in a small tensile testing machine as used in the testing of Portland cement. Different strengths were shown by specimens prepared in different ways. Good triaxial porcelain had a strength of 3000 to 6000 lb. per sq. in., while special high-temperature porcelains showed strengths up to 10,000 to 12,000 lb. per sq. in. The ratio of tensile to compressive strength was 5·9 for the special porcelains studied, and for triaxial porcelains had an average of 7·6. The tensile strength tests showed a little more variation than the compressive strength tests. The tensile strength gave more reliable indications of the impact resistance of porcelain than did the compressive strength.—H. S. H.

Glazes; The field of porcelain —— maturing between cones 17 *and* 20. R. Twells, jun. J. Amer. Ceram. Soc. 1922, 5, 430—439.

Porcelain glazes were prepared based on the formula $(0{\cdot}3K_2O,0{\cdot}7CuO),xAl_2O_3,ySiO_2$, where RO was kept constant, x varied between 0·8 and 1·6, and y varied from 6·0 to 1·6. The glazes were applied on green porcelain discs which were air-dried but which were dipped in water before dipping in the glaze. The body chosen was vitreous from cone 17—19, but was overfired at cone 20 if the firing period was long. The test-pieces were fired in commercial kilns to cones 17¾, 18, 19, and 20. It was found that fine crazing due to a relatively high flint content could be corrected by firing to a higher temperature, though it was better to decrease the flint content. Coarse crazing in glazes of high flux content seemed to be caused or accelerated by an increased firing temperature and could be remedied by increasing both the flint and clay content, the latter to a lesser extent than the former. The best glazes for temperatures between cones 17 and 20 have ranges of composition as follows:—clay 21·9 to 27·2%, flint 40·8 to 51·8%, felspar 17·2 to 23·6%, whiting 7·2 to 10·0%.—H. S. H.

Enamel reactions; Microscopic study of ground coat and cover coat ——. E. E. Geisinger. J. Amer. Ceram. Soc., 1922, 5, 322—337.

Ground coat and cover coat enamels were applied to steel pieces and the cross-sections of the enamel examined under the microscope after correct firing in an oxidising atmosphere and also after overfiring and after firing in a reducing atmosphere.

Excessive intermingling of ground coat and cover coat was observed due to their flowing temperatures being too close to one another, and also to the interaction between ingredients. The formation of large bubbles, with a resulting weak structure, was noted with enamels of high viscosity which did not allow the ready escape of occluded air and gases. Enamels of low viscosity formed a dense glass-like structure. The tendency to excessive gasification in the enamel on the ware at high temperatures could be seen. An enamel which was heterogeneous, showing some unmelted matrix, did not exhibit fish-scaling or shivering as did a dense glass-like enamel. An enamel showing excessive bubbling would often shiver, but one which contained small, uniformly dispersed bubbles was generally free from shivering and fish-scaling.
—H. S. H.

Glaze and enamel calculations; A modification of the empirical formula in ——. J. E. Hansen. J. Amer. Ceram. Soc., 1922, 5, 338—345.

The disadvantages of the usual type of molecular formula for enamels and glazes are reviewed and it is shown by calculation back to the batch mixture how the molecular formula may be misinterpreted. The following type of empirical formula is proposed:—(Na_2O, Na_2F_2, K_2O, CaO, CaF_2, BaO, ZnO, PbO), (Al_2O_3, Al_2F_6), SiO_2, SiF_4, B_2O_3, Sb_2O_3). It is claimed that this formula presents its data in a simple and graphic manner, and indicates the mineralogical and physical condition in which most of the important constituents are introduced into the batch. There is little danger of obtaining the wrong batch mixture upon calculating back to the raw materials, and the conclusions to be drawn from the formula are fixed and definite.—H. S. H.

Patents.

Glass; Manufacture of ——. Westinghouse Lamp Co., Assees. of A. H. Compton. E.P. 170,563, 15.9.21. Conv., 16.10.20.

A glass resistant to the chemical action of vapours of the metals of the sodium group contains no silica and is made by fusing at least 50% of boron oxide with one or more of the oxides (or substances which yield the oxide) of sodium, potassium, lithium, rubidium, cæsium, aluminium, calcium, barium, strontium, and magnesium. If the glass contains only boron oxide and one or more of the alkali metals it is soluble in water, but this can be avoided by adding one or more of the oxides of aluminium, calcium, barium, strontium, and magnesium.
—H. S. H.

Glass; Gathering of ——. H. Blanc. E.P. 182,011, 27.7.21.

A helical coil of piping through which cold water is flowing is lowered into the molten glass in the furnace. Within this coil is placed a similar but smaller coil which constitutes the gatherer. The local chilling of the glass produces a crust of glass between the convolutions of the gathering coil. The gathering coil is then raised and the glass removed is dropped into a receptacle placed at a higher point within the furnace and subjected to the hot furnace gases. The reheated glass is allowed to flow from this receptacle as required.—H. S. H.

Glass; Method and apparatus for the manufacture of ——. *Manufacture of glass.* R. Good, Assr. to Hazel Atlas Glass Co. U.S.P. (A) 1,421,210 and (B) 1,421,211, 27.6.22. Appl., 1.12.19.

(A) The batch is fed vertically downward into the glass-melting tank through one or more tapering pipes, wherein, by reason of the lessening diameter, the material is subjected to a progressively increasing temperature, until fusion is effected and the material flows into the tank. (B) The batch is heated in a vertical conical receptacle until it becomes semi-molten and flows into a tank, in which it is further heated by a heating medium out of contact with the batch until it is thoroughly molten and refined, and provides a continuous supply of glass ready for use.—A. B. S.

Glass; Method of producing non-shatterable ——. O. S. Marckworth. U.S.P. 1,421,974, 4.7.22. Appl., 26.3.19.

A method of producing non-shatterable glass comprises immersing the assembled glass and celluloid laminæ in a solution of fusel oil, camphor, and methyl salicylate at a temperature of 24°—35° C. and subsequently raising the temperature of the solution, applying pressure to the laminæ, and subjecting the parts to a progressively increasing temperature, during the application of pressure.
—H. S. H.

Sheet glass; Method and apparatus for producing ——. J. P. Crowley and C. A. Rowley, Assrs. to The Libbey-Owens Sheet Glass Co. U.S.P. 1,422,036, 4.7.22. Appl., 17.1.21.

Sheet glass is produced continuously by allowing a stream of molten glass to flow downward into a space between a pair of horizontal cylindrical metallic rollers, having their faces tinned. The rollers are cooled internally and are rotated in opposite directions in a heated chamber, the lower portions of the rollers dipping into receptacles containing molten tin. The thickness of the sheet of glass is regulated by varying the distance between the rollers. The sheet of glass is cooled as it emerges from the heated chamber enclosing the rollers.—A. B. S.

Kilns [*for burning ceramic wares*]. W. G. de Steigner. E.P. 181,502, 16.3.21.

A continuous kiln consisting of a heating chamber having a horizontal middle portion and downwardly inclined end portions is so heated as to be progressively cooler from the middle portion to the ends. Means are provided for moving a series of articles step by step through the kiln. The articles are maintained in an upright position throughout their passage through the heating chamber, the carriers being moved horizontally and vertically step by step.—H. S. H.

Clay; Process for weatherproofing ——. W. H. Allen. U.S.P. 1,421,888, 4.7.22. Appl., 6.9.21.

A coating of a weather-resisting medium is applied after calcium silicate has been deposited by chemical action in the surface pores of the unbaked clay.
—H. S. H.

Glass; Apparatus for forming window —— *by the lifting process.* W. G. Clark. E.P. 160,806, 29.3.21. Conv., 29.3.20.

Glass; Manufacture of raw plate —— *and method and apparatus for use therein.* A. W. Mathys. From Bicheroux Lambotte et Cie. E.P. 182,551, 1.4.21.

Refractory silica brick and process of manufacture. O. Rebuffat, Assr. to Pomilio Bros. Corp. U.S.P. 1,420,284, 20.6.22. Appl., 5.12.21.

See E.P. 159,865 of 1921; J., 1922, 464 A.

IX.—BUILDING MATERIALS.

Stucco and flooring; New developments in oxychloride ——. J. B. Shaw and G. A. Bole. J. Amer. Ceram. Soc., 1922, 5, 311-321.

A Californian magnesite was calcined at 1000° C. and a dolomitic limestone at 650°—700° C. and at 770°—800° C., about 18% of free lime being present after the latter calcination. Cements were prepared from these substances with calcium or magnesium chloride solutions, sawdust being used as a filler. The time of setting, shrinkage and tendency to crack on drying, specific gravity, and tensile strength were determined. It was found that magnesite must be diluted with some coarse aggregate to give a satisfactory cement with magnesium chloride. Cements made from dolomite were as satisfactory as those made from magnesite with an equal magnesia content, but free lime resulting from overburning the dolomite was injurious. Both dolomite and magnesite gave cements of higher tensile strength than Portland cement. Calcium chloride can be substituted for magnesium chloride only under special conditions, *e.g.*, the solution should be more dilute and less filler should be used. Mixtures of the two chlorides did not give as good cements as either separately. The effect of fineness of grinding, temperature and humidity of the atmosphere during setting, strength of the chloride solution, the addition of different kinds of coarse aggregate, expansion, and weathering on cements prepared from various dolomites was examined.—H. S. H.

Cement; Effect of low temperatures on the hardening of ——. H. Kreuger. Beton u. Eisen, 1922, **21**, 74—78. Chem. Zentr., 1922, **93**, IV., 32.

The objectionable action of frost on the setting of cement is prevented if the temperature is kept at 4—6° C. for 2 days before exposure to frost. Moist cement-mortar and concrete when exposed alternately to heat and frost attain a lower strength than under normal conditions. On keeping cement in air at temperatures between 0° and 16° C., the hardening proceeds more slowly the lower the temperature, but considerable hardening takes place even at 2° C.—A. B. S.

Yellow pine crude oil; Toxicity of Western —— *to Lenzites Saepiaria, Fries. Studies in wood decay.* H. Schmitz. J. Ind. Eng. Chem., 1922, **14**, 617—618. (*Cf.* J., 1921, 660 A.)

The low toxicity and high rate of evaporation of the crude oil from the distillation of Western yellow pine make it of little value as a general wood preservative. It may, however, be adapted to special uses, as in the manufacture of shingle stains and preservative paints. The toxicity was determined with sawdust from three species of wood as culture media. The toxicity point varies slightly with the species of wood used. It is suggested that an ideal way to determine the toxicity of wood preservatives to wood-destroying fungi would be to set up such a culture series as was used in this work, and to determine the actual decomposition of the wood as indicated by the loss in weight of the flasks. The disadvantage would be that at least three months would be necessary, during which a volatile preservative would evaporate considerably. The Petri dish method was also used in this investigation.

—H. C. R.

Patents.

Cement manufacture [and low-temperature carbonisation.] Merz and McLellan, and E. G. Weeks. E.P. 181,811, 17.3.21.

A cement kiln is worked in conjunction with a low-temperature carbonisation plant in such manner that the coke residue from the latter, with or without other fuel, is used to heat the kiln, and the exhaust gases from the kiln (with or without the sensible heat and/or heat of combustion of gas from the carbonisation plant) are used to raise steam for use in the carbonisation process.—A. B. S.

Stone; Process and composition for coating natural and artificial ——. W. Schneider. E.P. 182,213, 30.3.21.

Natural or artificial stone is coated with a mixture of a cementitious material (15 kg. of sulphur, 4 kg. of graphite or sandstone, and 1 kg. of small shot, melted together and afterwards ground and mixed with about half its weight of Portland cement or plaster of Paris), and a metal or metals, such as tin or lead, or an alloy melting at a low temperature. A hot iron is subsequently passed over the material to produce a smooth, continuous metal surface. A sheet of metal may be applied to the coating, whilst the metallic portions thereof are in a molten condition, and a portion of the coating may be cut away, so as to leave a raised design or inscription in metal.—A. B. S.

Insulating cement or mortar. A. S. Elsenbast and W. L. Jordan. U.S.P. 1,421,192, 27.6.22. Appl., 19.3.21.

An insulating cement is made of powdered diatomaceous earth, clay, and starch.—A. B. S.

Cement kilns; Method of utilising waste-heat gases of ——. J. E. Bell. U.S.P. 1,421,386, 4.7.22. Appl., 26.9.19.

A plant comprising a cement kiln, a waste-heat flue leading therefrom, and an element for utilising the heat of the gases in the flue is so operated that the waste gases in the flue contain a considerable amount of free oxygen. The temperature and heat efficiency of the gases in the waste-heat flue and heat-utilising element are increased by feeding finely divided fuel into the flue in such quantity that it combines with the free oxygen in the waste gases and raises the temperature of the whole body of gas.—H. S. H.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Boiler plates; Strength and elasticity of —— *at elevated temperatures.* H. J. French. Chem. and Met. Eng., 1922, **26**, 1207—1209.

In all grades of plates the tensile strength decreased at a temperature of about 95° C., increased to a maximum at about 290° C., and at 400° C. again approximated to the value at atmospheric temperature. The limit of proportionality increased to a maximum at about 150° C., firebox plate showing a more distinct change than the marine grade. Variation in the value of the proportional limit was not so marked at the higher temperatures. Elongation showed only a slight decrease until 95° C. was exceeded, after which a maximum value was obtained at 245° C., which temperature also marked a minimum value for the reduction in area. The maximum tensile strength did not coincide with the minimum value for the reduction in area or the maximum proportional limit.—C. A. K.

Manganese in steels, alloys, and ores; Colorimetric estimation of ——. J. Heslinga. Chem. Weekblad, 1922, **19**, 302—303.

Oxidation to manganate or permanganate is not suitable for colorimetric estimation if iron be present. The compound, H_2MnO_3, gives a brown colour in alkaline solution very suitable for the estimation. Trivalent metals and copper are precipitated from the solution of the sample by shaking for a few minutes with powdered zinc oxide. The filtered solution is added to a mixture of 3% hydrogen peroxide and 10% potassium hydroxide, and the colour produced compared with that given by a standard manganese solution. Lead does not interfere if excess of alkali be used; if nickel or cobalt be present potassium cyanide is added. 0·02 mg. of manganese is easily detected.—S. I. L.

Nickel; Structure of electrolytically deposited ——. V. Kohlschütter and H. Schödl. Helv. Chim. Acta, 1922, 5, 490—512.

It was shown by Kohlschütter and Vuillemier (Z. Elektrochem., 1918, **24**, 300) that, according to the conditions under which it is deposited, electrolytic nickel shows a linear contraction to a greater or less extent, and a method was devised for measuring this contraction. It was later found by Stäger (J., 1920, 787 A) that this contraction could be more or less eliminated by the use of depolarisers or by superposing on the direct current an alternating current. Comparisons have now been made of the micro-structures of different deposits, some of which showed contraction on deposition and some of which did not. Although the surfaces of the deposits differed in appearance their internal structures were practically indistinguishable. It is concluded that the phenomenon is purely a surface one involving aggregation of particles originally deposited in a highly disperse form. Deposits obtained with direct current were brittle, those obtained with a superposed alternating current were more flexible. There is no apparent relation between brittleness and the contraction effect. The brittleness is probably due to the presence of hydrogen in the metal. (*Cf.* J.C.S., Sept.) —E. H. R.

Nickel; Influence of superposed alternating current on the deposition and solution potential of ——. V. Kohlschütter and H. Schödl. Helv. Chim. Acta, 1922, 5, 593—609.

In this paper are recorded potential measurements made in the course of the investigation previously described (*cf. supra*). The superposition of an alternating current causes a lowering of the cathode potential more or less parallel with the lessening of the contraction effect in the metallic deposit. The relation, however, between the structure and contraction of the metal on the one hand, and the deposition potential on the other, may not be so close as at first appears to be the case. It is impossible to observe the structure of the deposit formed at an abnormally high cathode potential, since contraction, probably accompanied by a modification of structure, is almost instantaneous. Undoubtedly hydrogen is the dominant factor in these phenomena.—E. H. R.

Metals; Apparatus for the deposition of —— *on large surfaces by cathodic projection.* P. Lambert and A. Andant. Comptes rend., 1922, 175, 154—156.

The apparatus consists of two large concentric glass bell jars. The outer stands on a glass or enamelled plate, the joint being made by means of a rubber ring. The inner jar stands in a slot, cut in the plate, and filled with mercury. The vacuum is made by means of a Gaede mercury pump, combined with a preparatory pump. The inner jar and the annular space between it and the outer jar are simultaneously exhausted, the former through an iron pipe passing through the plate and forming at the same time the anode, and the latter through the neck which is provided with a ground-in stopper. The slight difference in pressure between the inner and outer bell jars does not cause the mercury in the slot to rise more than 1—2 cm. When the desired vacuum has been reached in the inner jar it is automatically cut off from the pump by a small mercury manometer, whilst the connexion is still maintained for the lower vacuum in the outer jar. The cathode is carried by an iron rod joined to a platinum wire which passes through the stoppers of the two bell jars. The cathode itself consists of an iron disc to which is attached a thin leaf of the metal to be projected.—G. F. M.

Liquid metals; Precipitation [segregation] in ——. W. Kroll. Metall u. Erz, 1922, **19**, 317—324.

In the liquation of metallic residues containing large proportions of tin, lead, and copper with smaller amounts of arsenic and antimony and a little iron, nickel, bismuth, and precious metals, the first runnings consist of the tin-lead eutectic containing most of the precious metals, whilst the iron and about half the arsenic, antimony, and copper remain in the portion still solid at 800° C. The remainder of the copper and antimony is distributed throughout the several fractions that have liquated at different temperatures. Addition of zinc or cadmium to the metal before liquating causes the antimony to go into the tin fractions and the copper to remain in the residue. Aluminium, on the other hand, holds the antimony, arsenic, and copper with itself in the residue. Experiments on the purification of lead, tin, and copper containing other metal impurities showed that antimony, arsenic, bismuth, sulphur, selenium, and tellurium may be precipitated, or caused to segregate, from the molten metal by addition of alkali or alkaline-earth metals, such as sodium or calcium, which form difficultly fusible compounds with these elements and in most cases do not remain themselves in the metal undergoing purification. Zinc, cadmium, and the precious metals are not affected by this treatment. Results of a number of tests carried out on antimonial lead, lead-bismuth, copper-antimony, and tin-antimony alloys are tabulated.—A. R. P.

Alloys; Analysis of —— *by the aid of specific heats.* K. Zahlbruckner. Chem.-Zeit., 1922, **46**, 637—638.

The proportion of two metals, of known specific heat, in an alloy may be found by determining the specific heat of the alloy by means of the usual water calorimeter, the value found being equal to the sum of the products of the percentage of each constituent present and its specific heat. In the case of a ternary alloy the proportion of one constituent must be found by chemical analysis, *or*, assuming that the specific gravity of the constituents is also known, by determining the specific gravity of the alloy and plotting two equations. In order to obtain results to 1% by this method the temperature measurements must be made in hundredths of a degree. Examples and graphs showing the application of the method are given. —A. R. P.

Gases from deflagrated metals. Thomson. *See* VII.

Patents.

Magnetic alloy sheets; Manufacture of ——. A. F. White. From The Valley Holding Corp. E.P. 181,401, 8.12.20.

In order to control the grain size of the metal the pressure and temperature are carefully regulated during the final rolling. The ingot is reduced in stages by heating the metal slowly to 1200° F. (650° C.), and then raising the temperature and rolling into sheets. The temperature of the metal before the final pass under controlled pressure is such that the finished sheet leaves the rolls at about the recalescence point of the metal. The heating processes are conducted so that the sheets are kept out of contact with the flame.—C. A. K.

Iron or steel articles; Process for coating —— *with lead with or without other metals.* W. J. Mellersh-Jackson. From Leadizing Co. E.P. 181,781, 19.2.21.

See U.S.P. 1,405,167 of 1922; J., 1922, 221 A. The solution may contain 40—50% by wt. of lead acetate and 5% or more of acetic acid; it is used at a temperature of about 70°—80° C.

Alloy steel; Process of making ——. J. McConnell, Assr. to Interstate Iron and Steel Co. U.S.P. 1,420,328, 20.6.22. Appl., 5.6.20.

A charge of crushed alloying metal and aluminium shot is added to molten open-hearth steel as it flows from the furnace into the ladle.—C. A. K.

Alloy steel. C. M. Johnson. U.S.P. 1,420,707–8, 27.6.22. Appl., (A) 6.8.20, (B) 28.3.21.

The steel contains (A) 10—20% Cr, 9—25% Ni, and 1—10% Si, or (B) 6—18% Cr, 12—36% Ni (the nickel being at least double the chromium content), 1—10% Si, and at least 50% Fe.—A. R. P.

Internal members of the human body; Material [steel] for artificial ——. F. Hauptmeyer. U.S.P. 1,421,776, 4.7.22. Appl., 3.9.20.

Chromium-nickel steel containing 18—23% Cr, 5—10% Ni, and 0·1—0·4% C is used for the manufacture of artificial internal members for the human body.—C. A. K.

Ferromanganese; Melting ——. J. H. Hall and R. D. Jordan, Assrs. to Taylor-Wharton Iron and Steel Co. U.S.P. 1,421,218, 27.6.22. Appl., 15.7.20.

Successive layers of ferromanganese and coke are charged into a cupola, together with a substance capable of neutralising the oxides produced during melting. The cupola is worked at its full capacity, and the molten ferromanganese is tapped off at frequent intervals.—C. A. K.

Alloys [e.g. aluminium-silicon alloy]; Method of producing ——. A. Pacz. E.P. 160,426, 18.3.21. Conv., 18.3.20.

A mixture of sodium silicofluoride and the requisite amount of aluminium powder to liberate the contained silicon is pressed into any suitable shape and introduced into a bath of molten aluminium at a temperature just above its melting point. The heat of the reaction may be utilised to introduce further quantities of silicon or other metal into the alloy, by adding the powdered metal to the mixture from which the briquette is made. A similar process may be used for alloying a metal of high melting point with one of a lower melting point, *e.g.* a mixture of aluminium and sodium zirconofluoride is added to molten iron, whereby an iron-zirconium alloy is obtained.—A. R. P.

Furnaces of the crucible type; Gas or oil heated ——. The Stockport Furnaces, Ltd., E. Duckworth, and A. Mead. E.P. 181,452, 9.3.21.

Cold gases for combustion are conveyed upwards through a spiral pipe fitted in an annular chamber in the walls of a crucible furnace and then downwards through a pipe to the burner. The spiral piping is of such a diameter as to extend from side to side of the annular chamber, and so forms a spiral flue for the products of combustion, which escape through an exit in the lower part of the wall of the furnace.—C. A. K.

Furnace for metallurgical and analogous purposes. Wellman Smith Owen Engineering Corp., Ltd., and A. V. Kemp. E.P. 181,863, 1.4.21.

In furnaces having superimposed arches or crowns, leaving a passage in which the air required for combustion is preheated, and a passage above for the waste gases from the furnace, the arch bricks are allowed to project into the passage-ways so as to provide a baffle arrangement.—C. A. K.

Melting furnace. A. J. Grindle, Assr. to Grindle Fuel Equipment Co. U.S.P. 1,420,312, 20.6.22. Appl., 3.3.22.

Combustion of pulverised fuel is effected in a combustion chamber at one end of a furnace, the floor of the combustion chamber being at a higher level than, and draining into, the hearth of the melting chamber.—C. A. K.

Metallic powders; Manufacture of ——. W. M. Gillespie and P. Buckley. E.P. 181,831, 21.3.21.

A solution of the required metal is electrolysed between an anode, consisting preferably of scrap metal, and a suitable cathode, the current density at the latter being such that the metal is deposited on it as a loose non-coherent powder which is continually removed by passing the electrolyte rapidly between the electrodes. The electrolyte is circulated through the cells by means of a pump, and the suspended metal is filtered off before the liquid is returned to the pump.—A. R. P.

Oxides of tungsten or molybdenum; Process for the reduction of ——. R. E. Pearson, E. N. Craig, and Durelco, Ltd. E.P. 181,837, 22.3.21.

Moist molybdenum or tungsten oxide or hydrated oxide is mixed to a paste with sulphuric acid, and the mixture is introduced into a porous pot surrounding a cathode consisting of a bundle of nickel-chromium alloy rods. The anode of the cell consists of a lead plate embedded in a mass of scrap molybdenum (or other easily oxidisable material) contained in a porous pot. On passing a direct current through the cell and agitating the paste surrounding the cathode, the oxide contained therein is reduced to a lower oxide from which, by suitable washing, impurities such as iron, calcium, and sodium salts may be more readily removed than from the original trioxide. At the same time the waste metal surrounding the anode is oxidised to trioxide, which is used to make further quantities of the reduced oxide. The latter, after washing and drying, is reduced to a metallic powder by heating in a current of hydrogen in known manner. —A. R. P.

Ores; Method of and apparatus for smelting ——. V. P. Y. Sacio. U.S.P. 1,419,764, 13.6.22. Appl., 26.4.19.

The bottom of a blast furnace discharges into a container of crucible shape detached from the furnace. The crucible is contained in an enclosed chamber, and an outlet allows the slag to fall down a vertical granulating column in which it preheats the air for the blast furnace.—C. A. K.

Tempering and annealing; Apparatus for ——. D. S. Lavaud, B. F. Clark, and C. W. Baines, Assrs. to The Metallurgical Plant Construction Co., Ltd. U.S.P. 1,420,379, 20.6.22. Appl., 2.3.22.

After treatment in a heating chamber, the heated articles are transferred to a cooling chamber in which a steam generator takes up the heat evolved from the heated material.—C. A. K.

Alloy of refractory metals [for filaments] and process of forming same. J. A. Yunck. U.S.P. 1,422,019, 4.7.22. Appl., 17.1.13. Renewed 14.7.21.

An alloy suitable for the manufacture of metal filaments consists of at least 95% of tungsten and the rest pure thorium.—A. R. P.

Metallurgical furnaces. H. D. Hibbard. E.P. 162,624, 29.4.21.

Nickel. Kohlschütter and Schödl. *See* X.

Patents.

Electrochemical reactions [oxidation of hydrocarbons to fatty acids, production of nitrates, hydrogenation, etc.]; Processes for carrying out —— and apparatus for use therein. G. Plauson. E.P. (A) 181,848 and (B) 181,849, 24.3.21.

(A) Electrochemical reactions are carried out in an electrolytic cell provided with an anode, the superficial area of which is very small compared with that of the cathode, and which is heated to a high temperature by the current. The electrolytes employed contain substances to be acted upon by nascent oxygen or its equivalent evolved at the anode, or if desired such substances are brought into the reaction zone at the anode in the form of solutions in organic solvents or as gases. Thus the substance may be introduced into the anode region through a tube, the end of which, projecting into the electrolyte, forms the anode. The gas evolved at the anode momentarily interrupts the current, so that the action is intermittent, whereby the breaking up of products formed during the electrolysis is hindered or prevented. The process is applicable to the production of substances of the nature of fatty acids, by the electrolysis of a solution of an alkali bisulphate with or without persulphate, and containing a hydrocarbon oil preferably in the form of an emulsion. Nitrates may be produced by the electrolysis of a salt of aluminium, magnesium, calcium, etc. while air or nitrogen is introduced at the anode. (B) The area of the cathode of an electrolytic cell is small compared with that of the anode and the electrolyte employed is such that an alkali metal is liberated at the cathode. The current density of the cathode is adjusted so that the temperature of the cathode exceeds 120° C. Substances such as oils, hydrocarbons, etc. are introduced into the immediate region of the cathode and undergo cracking, hydrogenation, polymerisation, etc. By suitable control of the temperature of the cathode, hydrogen and the alkali metal are produced, the former effecting hydrogenation of the added organic substance under the catalytic action of the alkali metal. If desired, salts of platinum, palladium, nickel, etc. may be added to the electrolyte, the catalytic action being accelerated by the liberation of these metals at the cathode.—J. S. G. T.

Electric furnace. K. Leander, Assr. to Ludlum Electric Furnace Corp. U.S.P. 1,420,561, 20.6.22. Appl., 19.5.20.

The furnace roof is supported in a frame so that it can be adjusted vertically, and the independent furnace body is moved into and out of position beneath the roof. Electrodes supported by the frame pass through the roof to the furnace, and means are provided for tilting the frame, furnace body, roof, and electrodes in order to discharge the furnace.—J. S. G. T.

Electric furnace. S. N. Castle. U.S.P. 1,420,687, 27.6.22. Appl., 13.8.18.

The walls of the crucible of an electric induction furnace are inclined to the vertical at an angle not less than 15°, and the bath contained in the crucible is interlinked with the core of the furnace. Windings supported at a higher level than the bath are likewise interlinked with the core.—J. S. G. T.

[Electrolyte for] electric storage battery. E. Hacking. U.S.P. 1,421,217, 27.6.22. Appl., 11.5.22.

An electrolyte for electric storage batteries consists of a gelatinous mass of sulphuric acid, sodium silicate, and mercury bisulphate, impregnated with mineral oil.—A. B. S.

Electrolytic cell. J. Harris, Assr. to Carbo-Oxygen Co. U.S.P. 1,420,037, 20.6.22. Appl., 4.8.19.

XII.—FATS; OILS; WAXES.

China wood oil [tung oil]. K. H. Bauer and K. Herberts. Chem. Umschau, 1922, **29**, 229—232.

China wood oil contains practically no saturated fatty acid and very little oleic acid, elæostearic acid, $C_{18}H_{32}O_2$, being the characteristic acid. Both the glyceride and the fatty acid (α-acid) derived from it change to isomeric (β) forms of higher m.p. by exposure to light or by the influence of catalysts such as iodine or sulphur. The oil obtained by extraction of the seed with a solvent containing sulphur, *e.g.*, carbon bisulphide, contains the glyceride of the β-acid. The bromo-derivative of α-elæostearic acid, although having a m.p. very close to that of the bromo-derivative of linolic acid (114° and 114·5° C. respectively) is not identical with the latter, as a mixture of the two bromo-derivatives has a lower m.p. On debromination of the bromo-derivative of α-elæostearic acid, neither linolic acid nor α-elæostearic acid (m.p. 48° C.) is obtained, but β-elæostearic acid (m.p. 68°—70° C.). On esterification of α-elæostearic acid with methyl alcohol and sulphuric acid and subsequent separation of the fatty acid, β-elæostearic acid is obtained, a result attributed not to the action of alkali, but to that of the acid used for esterification. However, on saponification of α-elæostearic acid anhydride and liberation of the acid, the α-form remains unchanged. (*Cf.* Morrell, J., 1918, 181 T).—A. de W.

Oil of grape seeds. The solid fatty acids. Method of separation of stearic and palmitic acids. E. André. Comptes rend., 1922, 175, 107—109. (*Cf.* J., 1921, 477 A, 518 A.)

From the solid fatty acids, obtained from the oil of grape seeds, the author has isolated stearic, palmitic, and melissic acids. The last-named acid probably comes from the waxy layer on the outer covering of the seeds. Palmitic and stearic acids may readily be separated for identification by fractional precipitation of their lithium salts from a solution of the mixed acids in 95% alcohol.—W. G.

Lemon seeds; Oil of ——. A. H. Bennett. Perf. Essent. Oil Rec., 1922, 13, 260.

Dried lemon seeds contain about 31% of their weight of an oil, which after either hot or cold expression, had the following analytical characters:—acidity 11·6% (as oleic acid), saponif. value 189, iodine value 109, sp. gr. 0·9227, titre of fatty acids 31·9° C., mol. wt. of fatty acids 281. The oil had a bitter flavour, and was of a clear orange colour when obtained by cold extraction, but much darker when prepared by hot extraction.—G. F. M.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Boiled oil substitutes as protective compositions; Examination of —— *with special reference to their rust-inhibiting properties.* Maass and Junk. Z. angew. Chem., 1922, 35, 353, 360—363.

An investigation was undertaken during the war by the *Reichsausschuss für Metallschutz* to determine how far linseed oil could be replaced by materials entirely obtainable within the Central Empires for making products for use by the railway and postal services as rust-preventing and other protective coatings. Since the substances commonly used as paint oil substitutes, *i.e.*, calcium and zinc rosinates, coumarone resin, and phenol-aldehyde condensation resins, in coal-tar solvents, either furnished unsuitable films or were too scarce at the time, attention was directed to products from coniferous wood tar, dissolved in a volatile solvent, particularly as tar fractions had from previous experience shown favourable results in rust inhibition. The tests applied comprised behaviour on application to non-absorbent (glass, iron) and absorbent surfaces (plaster, pasteboard, wood), spreading power as determined by absorption on porous surfaces, elasticity and adhesion of the dried film (bending tests), weather-resistance, resistance to changes of temperature, resistance to water vapour at 80° C., water absorption and impermeability to water, and rust-inhibiting properties. On the whole the products examined (excepting one which contained 30% of linseed oil) compared unfavourably with boiled linseed oil excepting in so far as impermeability and rust-inhibition were concerned. It was concluded that linseed oil could be partly replaced in protective coatings if results up to a certain limit of efficacy only were desired.—A. de W.

Drying oils from petroleum and other products, produced by chlorination and dechlorination. H. A. Gardner and E. Bielouss. J. Ind. Eng. Chem., 1922, 14, 619—621.

A non-viscous "neutral" mineral oil consisting chiefly of hydrocarbons from $C_{17}H_{36}$ to $C_{26}H_{54}$ was successfully chlorinated without the use of any catalyst. The amount of chlorine fixed was sufficient to form tri- and tetra-chlorides. The dechlorination was carried out, without the use of any catalyst or absorbing agent for the hydrochloric acid produced, by heating the chlorinated compounds to 250° C. A partial saturation of the ethylenic linkages primarily formed takes place owing to the formation of cyclic hydrocarbons. The iodine values of the products usually varied between 70 and 130. Semi-drying oils such as soya-bean and cottonseed oils were also treated in the same way and their drying properties were greatly improved.—H. C. R.

Patents.

Pigment and methods of producing the same. P. Fireman, Assr. to Magnetic Pigment Co. U.S.P. 1,420,985, 27.6.22. Appl., 8.4.21.

Ferrous hydroxide is precipitated from a solution of a ferrous salt and the liquid and precipitate are heated and subjected to the action of air for 10—15 hrs., whereby a dark brown pigment is obtained.
—J. R.

Pigments; Method of making binders for —— [*for printing ink*]. H. A. Buck, Assr. G. Moore. U.S.P. 1,421,125, 27.6.22. Appl., 21.6.20.

A non-inflammable printing ink consists of a pigment thoroughly incorporated in a non-inflammable binder containing shellac, borax, and water.
—D. W.

Paint and process of making same. C. A. Ward. U.S.P. 1,421,625, 4.7.22. Appl., 11.2.20.

A mixture of aluminium and zinc stearates is intimately mixed with a pigment and suspended in a vehicle.—D. W.

Resinous condensation products from phenolic acids and aldehydes; Process for preparing ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 339,495, 16.11.19.

Aromatic hydroxycarboxylic acids are heated with aldehydes or substances producing aldehydes. Small

quantities of acid or basic condensing agents and solvents may be present. For example, salicylic acid may be heated with 30% formaldehyde and water for 20 hrs. and the whitish precipitate produced separated, freed from excess of water and further heated until a sample sets to a clear glass-like substance. The duration of treatment may be shortened by adding a catalyst such as hydrochloric acid. The resin obtained is hard and of high melting point and is soluble in alcohol and acetone, in weak alkalis such as sodium carbonate, borax, and ammonia solution, and in paraldehyde. It is suitable for leather-finishing and for treating felts in the manufacture of hats. Similar resins are obtained from hexamethylenetetramine and mixtures of *o*- and *p*-hydroxybenzoic acids; from 1.3.4-hydroxytoluic acid and paraformaldehyde in the presence of ammonium acetate; and from salicylic acid and benzaldehyde in the presence of ammonia. These products are of yellow to yellowish-red colour and in consequence of their solubility in weak alkalis can be used as substitutes for shellac.
—H. C. R.

[Resinous] condensation products from hydrocarbons; Process for the production of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 349,741, 12.7.18.

The hydrocarbon is treated with formaldehyde or substances yielding formaldehyde in the presence of sulphuric acid of concentration below 60%. For example if naphthalene is heated to 110°—115° C. with 40% formaldehyde and sulphuric acid (66° B., sp. gr. 1·84) a white resin is obtained which is soluble in acetone, benzene, solvent naphtha, carbon tetrachloride and carbon bisulphide. Phenanthrene gives under the same conditions a brownish-yellow, brittle resin soluble in benzene and xylene, anthracene a yellow resin soluble in benzene. Benzene heated under pressure to 118°—125° C. with 40% formaldehyde and 96% sulphuric acid gives a soft brown resinous mass soluble in benzene. Toluene gives a clear liquid soluble in ether, acetone, benzene, chloroform, and carbon tetrachloride. Xylene heated for six hrs. with 40% formaldehyde and 96% sulphuric acid gives a brown resin soluble in acetone, benzene, carbon tetrachloride, and solvent naphtha. The products melting below 100° C. are of value in the varnish industry.
—H. C. R.

Oils suitable for impregnating films and keeping them soft; Process for manufacturing ——. Petri und Stark, Ges. m. b. H. G.P. 349,088, 22.3.19.

Benzyl alcohol is treated with 50—80% sulphuric acid at a low temperature and for a short time so that no formation of resin occurs. A pale yellow or brownish viscous oil is obtained which is practically free from odour, has a much higher boiling point than benzyl ether, and is easily taken up by tissue and animal membranes and firmly retained by them.—H. C. R.

Dye for documents; Method of making an indestructible black stamp ——. J. Schiffmann. U.S.P. 1,421,728, 4.7.22. Appl., 8.8.21.

See E.P. 172,588 of 1921; J., 1922, 66 A.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation of rubber in solution. F. Boiry. Comptes rend., 1922, 175, 102—104.

If rubber, in solution in an organic solvent, is heated with sulphur at about 120° C. the nature of the product depends on the concentration of the solution and the solvent used. With dilute solutions (1—2%) and with solvents such as nitrobenzene, petrol, phenetol, etc., a gelatinous deposit is obtained which, when dried, is a hard elastic mass with a black fracture. After extraction with acetone it contains 15—30% of "combined" sulphur, depending on the conditions. With solvents such as aniline, xylene, thymol, etc. no precipitate is obtained even after boiling for several weeks. With 10% solutions, in solvents of the first group, the viscosity of the solution at first diminishes on heating, until it reaches a minimum, after which it rises first slowly and then rapidly until the liquid forms a gel. These gels show the phenomenon of syneresis. The sulphur content of the products obtained after extracting these gels with acetone is 20—30%.—W. G.

Patent.

Rubber; Process for heat vulcanisation of ——. R. Wheatley, and The Victoria Rubber Co., Ltd. E.P. 181,802, 17.3.21.

Cylinders, presses, jacketed autoclaves, and dry heat chambers for vulcanising are heated by means of one or more substances (other than a solution) having a boiling point higher than water, so that high temperatures can be obtained at low pressure. The substance or substances, *e.g.* aniline oil, are circulated between the source of heat and the vulcaniser.—D. W.

XV.—LEATHER; BONE; HORN; GLUE.

Hide; Bacteriology of fresh steer ——. G. D. McLaughlin and G. E. Rockwell. J. Amer. Leather Chem. Assoc., 1922, 17, 325—340.

The authors have isolated and studied a number of bacteria from fresh hide. Experiments on pieces of hide show that the presence of proteolytic bacteria, protein matter such as blood, a slightly alkaline medium, a moderately high temperature, the presence of oxygen and small traces of carbon dioxide favour bacterial decomposition of the hide, whilst the absence of proteolytic bacteria, acidity, the presence of fermentable carbohydrates, a large excess of carbon dioxide, the absence of oxygen, and a low temperature tend to prevent it.—D. W.

Chrome tanning. X. Modern problems in chrome tanning. D. Burton. J. Soc. Leather Trades' Chem., 1922, 6, 226—234.

The swelling power of a chrome liquor is dependent on the free acidity, the neutral salt content, the relative rates of absorption of acid and further hydrolysis of the chromium salt, and the relative rates of absorption of acid and fixation of the grain by the chromium compound. Organic substances in the chrome liquor exert a favourable influence. If sulphuric acid is replaced by a weaker acid, the chrome liquor will have a lower hydrogen ion concentration, produce less swelling and therefore give a softer leather. The procedure in tanning, the completion of the tannage, and ageing are also discussed.—D. W.

Chrome tanning. Equilibria between tetrachrome-collagen and chrome liquors. Formation of octa-chrome-collagen. A. W. Thomas and M. W. Kelly. J. Ind. Eng. Chem., 1922, 14, 621—623.

Measurement of the fixation of chrome by hide substance after contact for 8½ months with chrome liquors of various concentrations showed that maximum fixation occurred in a liquor containing 1·5 g. Cr_2O_3 per 100 c.c. The chrome-collagen compound formed in this liquor proved to be an octa-chrome-collagen, showing that the combining weight of collagen is as low as 94. The changes taking place when tetrachrome-collagen is in contact with chrome liquors over a similar time interval have been measured and show that the formation of tetrachrome-collagen is not strictly reversible. This supports the view that the absorption of chrome from chrome liquors by collagen is a chemical reaction.—H. C. R.

Chrome leather analysis. A modified method of determining the amount of alkali salts in chrome leather. D. Woodroffe and R. E. Green. J. Soc. Leather Trades' Chem., 1922, **6**, 222—223.

The leather is ashed, the ash treated with strong sulphuric acid, the excess of which is evaporated off, the residue ignited, the soluble sulphates extracted with boiling water, and estimated with barium chloride.—D. W.

Tannin analysis; A contribution to the method of ——. J. Schneider, jun. J. Soc. Leather Trades' Chem., 1922, **6**, 234—239.

For the purpose of determining total soluble matter, total solids, and non-tans, aliquot weighed portions should be employed instead of measured portions, as more accurate results are obtained. Dry chromed hide powder gives good results.
—D. W.

Tannin-analysis; Note on the Wilson-Kern method of ——. G. W. Schultz. J. Amer. Leather Chem. Assoc., 1922, **17**, 348—352.

Recent work by Thomas and Kelly (*cf.* J., 1922, 383 A) is quoted to controvert the Wilson-Kern method of analysis. A portion of the tannin absorbed by the hide powder in shake experiments is removed by washing. In strong tannin solutions, the surface of the hide particles is so completely tanned as to prevent further penetration of the tannin. The introduction of air-dry powder into tannin solutions does not parallel tannery practice.
—D. W.

Gelatin swelling; Note on the lyotrope-adsorption theory of ——. H. G. Bennett. J. Soc. Leather Trades' Chem., 1922, **6**, 223—226.

A criticism of the Procter-Wilson theory of gelatin swelling and of a recent paper by Atkin (*cf.* J., 1922, 475 A). The author affirms that the swelling of gelatin is caused by the adsorption of ions modified by the lyotrope effects of the dissolved salts.
—D. W.

Sodium sulphide. Atkin. *See* VII.

Patents.

Hides and skins; Depilation of ——. O. Richter. E.P. 182,240, 13.4.21. Addn. to 175,314 (J., 1922, 304 A).

The hides or skins are degreased prior to, or during the early stages of depilation, and protected on the flesh side against penetration by ammonia by suitable coatings or by being placed flesh to flesh. Warmed concentrated ammonia is used in place of steam to maintain the requisite degree of moisture. The hides or skins may be kept in motion, or the vapours may be circulated. The unconsumed ammonia is expelled from the chamber by warm air or other gases which do not react with the ammonia, and the latter is recovered.—D. W.

Tanning agent for the chrome tannage of leather; Preparation of a ——. A. Glover and G. Martin. E.P. 182,289, 26.5.21.

Aqueous solutions of sodium or potassium bichromate and sulphuric acid are reduced with dried whey powder.—D. W.

Tanning hides; Process for ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 349,363, 30.9.17. Addn. to 334,004 (J., 1921, 400 A).

Ferric salts dissolved in solutions containing formic acid, with or without the addition of other tanning agents or accelerators, are used as tanning agents. For example, pickled pelts are treated with a liquor containing anhydrous ferric sulphate, sodium formate, and formic acid, with or without the addition of 30% formaldehyde and sulphite-cellulose extract. When the ferric salt has penetrated uniformly throughout the skin, an aqueous solution of sodium carbonate is added, and the skin is treated for several hours more in the solution. The use of formic acid reduces the time of the tanning process.

Glue, gelatin, and the like; Apparatus for the extraction of ——. F. H. Tunnell. U.S.P. 1,421,620, 4.7.22. Appl., 10.12.20.

The apparatus comprises an open tank having a perforated false floor spaced from the bottom and sides, a standpipe extending from the floor to a point above the top of the tank and having openings and a deflector adjacent its upper end, means for withdrawing liquid from the tank, heating means below the false floor, a screen disposed around the peripheral edge of the false floor and inwardly inclined to it, and means adjacent the bottom of the standpipe to direct a column of fluid upwards therein.—D. W.

Glue from the waste liquors from cellulose manufacture; Process for manufacturing ——. H. P. Kaufmann. G.P. 352,138, 19.3.18.

The liquors are evaporated to a thick paste or a dry powder and this is mixed with casein and lime or casein, lime, and a salt of an alkali metal. The product is characterised by greater strength and waterproof qualities than other glues made from cellulose liquors.—H. C. R.

Tanning with aluminium salts; Process for ——. O. Röhm, Assr. to The Chemical Foundation, Inc. U.S.P. 1,421,723, 4.7.22. Appl., 6.12.17.

See E.P. 110,750 of 1917; J., 1918, 217 A.

Glue; Manufacture of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 181,865, 2.4.21.

See G.P. 344,238 of 1921; J., 1922, 186 A.

XVI.—SOILS; FERTILISERS.

Soil; Presence of cobalt and nickel in arable ——. G. Bertrand and Mokragnatz. Comptes rend., 1922, **175**, 112—114.

In a very fertile, arable soil from near Belgrade the authors have found 0·00028% of cobalt and 0·00136% of nickel and in a garden soil 0·00037% of cobalt and 0·00174% of nickel.—W. G.

Humus; Determination of —— by oxidation with chromic acid. A. Gehring. Z. anal. Chem., 1922, **61**, 273—278.

To determine humus in soil a sample is treated in a flask with dilute sulphuric acid to decompose carbonates, a current of air being passed through the flask to remove the carbon dioxide. Potassium bichromate is then added and the mixture heated while the current of air is continued; the gases resulting from the oxidation of the organic matter are passed through a heated tube containing copper oxide and lead chromate, and the carbon dioxide is then collected in a potash bulb and weighed.

XVII.—SUGARS; STARCHES; GUMS.

Beet raw sugars; Loss of sucrose in the refinery in the working of ——. J. E. Duschsky and P. G. Galabutsky. Z. Ver. deuts. Zuckerind., 1922, 401—416.

DURING the re-melting of sound "sand sugar" it is unnecessary to add lime or other alkali, since, whether a coil or direct steam be the means of heating, the amount of inversion that occurs can hardly be detected. On the other hand, when working with deteriorated sand sugar, which contains invert sugar, and has become more or less acid, alkali must be added, but the amount should be little more than that required for neutralisation, viz., an alkalinity of 0·001% CaO. It is held that a greater excess of alkali is irrational, since it causes the darkening of the liquors, and leads to an increase of the salt content of the syrup and consequently to a greater amount of final molasses. During the re-melting of deteriorated sand sugar, solution must be effected as rapidly as possible, and direct steam should be used for heating. Any unnecessary delay before discharging the syrup from the pans should likewise be avoided.—J. P. O.

Sugars; Insoluble matter content of direct consumption ——. J. P. Ogilvie. Int. Sugar J., 1922, *24, 368—369.*

IN Demerara and Trinidad yellow crystals the total insoluble matter was found to vary between 10 and 48 mg. per 100 g. of sample, and in plantation white sugars between 13 and 25 mg., of which about half consisted of inorganic matter.—J. P. O.

[*Sugar*] *cane juice; Determination of the Brix degree of raw* ——. W. D. Helderman. Archief, 1921, **29**, 1708—1713. Int. Sugar J., 1922, **24**, 381.

IF raw cane juice, which refuses readily to subside and de-aerate, be heated with about 2% of kieselguhr rapidly to boiling point in a flask fitted with a reflux condenser, cooled, and filtered, a clear liquor practically free from air, serving well for the Brix degree determination is obtained, the reading found agreeing closely with that given by the same juice which has been allowed to subside during one hour. Juice thus treated with kieselguhr should not, however, be used also for the determination of the sucrose and reducing sugars content, since during the process of heating some inversion generally occurs.—J. P. O.

Carbohydrates; Sublimation experiments with ——. P. Karrer and J. O. Rosenberg. Helv. Chim. Acta, 1922, 5, 575—576.

PICTET and Sarasin (J., 1918, 49 A) have shown that lævoglucosan is formed when starch is distilled at a low pressure. The same product has now been obtained as a sublimate by heating potato starch at about 220° C. in a very thin layer, having a cold condensing surface within 2 mm. of the heated starch, at atmospheric pressure. From α-tetramylose the same product was obtained, but by heating rhamnose at 120° C. (12 mm.) the sugar itself was sublimed.—E. H. R.

Galactosan. A. Pictet and H. Vernet. Helv. Chim. Acta, 1922, 5, 444—448.

WHEN galactose is dehydrated at 180° C. (15 mm.) the molecular weight of the product corresponds with $(C_6H_{10}O_5)_2$; at 135° C. (2 mm.) a mixture of galactosan, $C_6H_{10}O_5$, and its dimeride is formed. The galactosan can be partially purified by extraction with boiling alcohol. Chemically it behaves like glucosan and is therefore an anhydride of the α-series. In cold hydrochloric acid it forms α-galactosyl chloride, which condenses in alcoholic solution with glucose and sodium to form a new disaccharide, glucose-α-galactoside. The osazone of this new sugar has m.p. 158° C. (*Cf.* J.C.S., Sept.) —E. H. R.

Decolorising carbon; Capacity of —— *for absorbing water.* A. Scholz. Chem.-Zeit., 1922, **46**, 652.

A GOOD decolorising carbon such as that used in the sugar industry can absorb up to 45% of its weight of water without appearing at all moist. With an equal weight of water it forms a moist powder which just balls together, while with 1½ times its weight of water it first assumes the characteristics of damp slime.—A. R. P.

Samuela carnerosana fruit. Black and Kelly. *See* XX.

XVIII.—FERMENTATION INDUSTRIES.

Grain; Method of utilising the component substances of —— *for the maximum production of material useful as food or in industry.* A. Sorel. Bull. Assoc. Chim. Sucr., 1922, **39**, 358—362.

THE grain is ground to flour and digested with malt at 60°—62° C. to saccharify the starch. Lactic fermentation is allowed to proceed for a brief period in order to render soluble mineral matter ultimately to be used as a yeast food. Excessive *production of lactic acid is checked by the addition of vinasse, previously concentrated under reduced* pressure *below 65° C. Yeast is added and allowed* to act for some hours. Alcohol is distilled off at atmospheric pressure. The yields of alcohol and of yeast were 36% and 24% respectively by the Viennese yeast process; and 25% and 35% respectively by the aero-yeast method.—A. G. P.

Glycerol; Fermentation of —— *in presence of sulphur.* H. and L. Müller. Helv. Chim. Acta, 1922, 5, 628—629.

IN presence of sulphur, glycerol is attacked by yeast with the formation of carbon dioxide and hydrogen sulphide. The sulphur probably oxidises or dehydrogenates the glycerol into a fermentable compound, according to the equation $C_3H_8O_3+S=C_3H_6O_3+H_2S$. (*Cf.* J.C.S., Sept.)—E. H. R.

Formaldehyde; "Alcoholic fermentation" of ——. H. Müller. Helv. Chim. Acta, 1922, 5, 627—628.

THE reaction involved in the "alcoholic fermentation" of formaldehyde in presence of osmium (J., 1922, 118 A), $3CH_2O+H_2O=2CH_3OH+CO_2$, can be accounted for by Cannizzaro's reaction. Assuming 4 mols. of formaldehyde to give 2 mols. each of methyl alcohol and formic acid, the latter can behave as an aldehyde and by the same reaction give, from 2 mols. of formic acid, 1 mol. of formaldehyde and 1 mol. of carbon dioxide. The net result corresponds with the above equation. —E. H. R.

Lactic acid; Destruction of —— *by yeast cells.* F. Lieben. Oesterr. Chem.-Zeit., 1922, 25, 87—90.

LACTIC acid being one of the products of the degradation of carbohydrates in muscle, experiments were made *in vitro* to determine the ultimate fate of this substance under the influence of the enzymes of the yeast cell, which appear to be similar, at least, to the muscle enzymes. It was found that lactic acid disappeared to within 3—5% in 7—8 hours, under suitable conditions, and that about two-thirds of its carbon content appeared in the products as carbon dioxide, either liberated as such, or remaining combined with soda; the remainder of the carbon was represented by an increase in weight of the yeast substance, and if calculated as $C_6H_{10}O_5$ practically accounted, together with the carbon dioxide, for the whole of the lactic acid which had disappeared. It appears, therefore, that both synthesis and degradation had occurred simultaneously. No other degradation products than carbon dioxide could be detected. Similar experiments were made with vegetable acids and with amino-acids: the former were not attacked; the latter were in part consumed by the yeast, but no degradation to carbon dioxide could be detected.—G. F. M.

Brandy; Critical study and new contribution to the analysis of ——. G. Bonifazi. Mitt. Lebensmittelunters. u. Hyg., 1922, **13**, 69—95. Chem. Zentr., 1922, **93**, IV., 62—63.

The characteristics of the different kinds of brandy, including artificial brandies, are enumerated and the methods in use for differentiating between them are described. The Micko process for the fractional distillation of the esters after saponification is described in the original, and the results of its application to a number of samples of brandy are given. This method is a very valuable one for the analysis of brandies. It allows of organoleptic tests on the different fractions and also of carrying out other determinations which are necessary for judging the sample. Among these, the appearance of a maximum ester value in the fourth or fifth fraction is of importance, as it appears to be proportional to the ester value. This maximum value *only occurs in the case of natural and adulterated brandies, and not in the case of artificial* brandies. The ratio ester value/maximum value varies within narrow limits for natural brandies. The higher this ratio the more doubtful is the quality of the brandy.—H. C. R.

Brandy; Detection and estimation of vanillin in ——. T. von Fellenberg. Mitt. Lebensmittelunters. u. Hyg., 1922, **13**, 98—110. Chem. Zentr., 1922, **93**, IV., 63.

100 c.c. of the brandy is distilled, using a fractionating column of glass balls, until only 10 c.c. is left behind. The residue is shaken 300 times with 10 c.c. of ether and the aqueous solution discarded. Any emulsion that forms is broken by centrifuging. The ether solution is shaken twice with 2 c.c. of water, giving 100 shakes each time, and then treated with 3 c.c. of saturated (40%) sodium bisulphite solution and shaken for 5 min. The aqueous layer is washed twice with 2 c.c. of ether, shaking 100 times at each washing, and transferred to a beaker with 3 c.c. of sulphuric acid solution (1:1) and 1 c.c. of water, heated to boiling, and, after cooling, shaken with its own volume of ether. The ethereal solution is washed with water, dried over calcium chloride, and evaporated to 1 c.c. This is transferred to a clock glass which is covered by another one cooled with ice. The ether is evaporated off and the residue sublimed by heating it over a spirit lamp about 15 cm. away. After 10—15 min. the top glass is changed and tested by odour and microscopical examination for vanillin. If a visible sublimate is obtained the clock glass condenser is changed every 10 min. until a sublimate and the odour of vanillin are no longer obtained. The sublimates are dissolved in ether, united in a test-tube, and after evaporating the ether, tested colorimetrically by adding bromine water (0·1—0·3 c.c.) until a permanent odour of bromine is obtained, removing the excess by blowing in air, and adding 1% ferrous sulphate solution, drop by drop. The presence of vanillin is indicated by a bluish-green coloration. The quantity may be estimated by comparison with solutions of vanillin of known concentrations. Quantities of vanillin up to 0·1 mg. per litre may come from the wood of barrels. The addition of vanillin is not indicated if less than 0·2—0·5 mg. per litre is found.

Distilling alcoholic and other liquids; Process of and apparatus for ——. H. Wade. From J. Schneible. E.P. 182,069, 13.1.21.

In a sectional column still for the distillation of alcoholic and other liquors, baffle rings and discs, preferably inclined downwards towards their free edges, are arranged alternately, and between the rings and discs are sets of vertical guide vanes, each guide vane being set at an angle to the radius of the still. The guide vanes impart a whirling movement to the rising vapours and descending liquid in the column and thus prevent channelling and promote intimate mixing of the vapours and distillate. Preferably the baffle rings and discs are connected together by means of the guide vanes, and each section of the still contains a baffle ring and disc and a set of guide vanes. The still may be provided with a removable cut-off section adapted to intercept liquid descending in the still and to permit its being drawn off if necessary.

XIXa.—FOODS.

Ash of foodstuffs; Alkalinity of ——. B. Pfyl. Z. Unters. Nahr. Genussm., 1922, **43**, 313—339.

The most useful values to be determined are the intrinsic alkalinity, the methyl-orange alkalinity, and the total phosphate of the ash. The first may be defined as the excess, expressed in milli-equivalents, of Na',K',Ca'',Mg'', which, after combination with PO_4''',SO_4'',Cl', remains for O'' and the weakly acid anions, CO_3''.SiO_3'',BO_2'.MnO_3'', MnO_4'',AlO_2''. If the anions are in excess the difference is expressed as intrinsic acidity. The methyl orange alkalinity is the excess, expressed in milli-equivalents, of the same four cations which, after combination with the anions, $\mathrm{H}_2\mathrm{PO}_4'$,$\mathrm{SO}_4''$,$\mathrm{Cl}'$, remains for O'' and the above enumerated weakly acid anions. Excess of anions is indicated as methyl-orange acidity. The total phosphates is expressed in milli-equivalents of PO_4'''. These three values can be obtained by titration first with methyl orange and then with phenolphthalein as indicator. Full details of simple methods of carrying out the above determinations, based on many years' experience, are given. Modifications necessary in special cases and precautions and corrections to be applied where special accuracy is needed are also indicated. The above three values are usually cal-

Yeast; Process for drying ——. E. Klein. U.S.P. 1,420,558, 20.6.22. Appl., 24.3.22.

Coarsely subdivided yeast is dried by a current of an innocuous gas at such a low temperature as not to destroy the vitality of the yeast, and is simultaneously subjected to a pulverising action so that the particles of pulverised yeast are carried off in the gas current, from which the yeast is subsequently separated.—J. R.

Dried yeast and method of making the same. A. W. Hixson. U.S.P. 1,420,630, 27.6.22. Appl., 20.12.20

Compressed yeast is subjected to slow gradual drying for a protracted period until a product is obtained containing substantially 10% of moisture.
—J. R.

Yeast; Process of preparing dried ——. E. Klein. U.S.P. 1,420,557, 20.6.22. Appl., 24.3.22.

See E.P. 175,623 of 1922; J., 1922, 605 A.

XIXA.—FOODS.

Ash of foodstuffs; Alkalinity of ——. B. Pfyl. Z. Unters. Nahr. Genussm., 1922, **43**, 313—339.

The most useful values to be determined are the intrinsic alkalinity, the methyl-orange alkalinity, and the total phosphate of the ash. The first may be defined as the excess, expressed in milli-equivalents, of Na', K', Ca'', Mg'', which, after combination with PO_4''', SO_4'', Cl', remains for O'' and the weakly acid anions, $CO_3'', SiO_3'', BO_2', MnO_3'', MnO_4'', AlO_2''$. If the anions are in excess the difference is expressed as intrinsic acidity. The methyl orange alkalinity is the excess, expressed in milli-equivalents, of the same four cations which, after combination with the anions, H_2PO_4', SO_4'', Cl', remains for O'' and the above enumerated weakly acid anions. Excess of anions is indicated as methyl-orange acidity. The total phosphates is expressed in milli-equivalents of PO_4'''. These three values can be obtained by titration first with methyl orange and then with phenolphthalein as indicator. Full details of simple methods of carrying out the above determinations, based on many years' experience, are given. Modifications necessary in special cases and precautions and corrections to be applied where special accuracy is needed are also indicated. The above three values are usually calculated to 100 g. of dry foodstuff or 1 litre of liquid, but occasionally to 1 g. of ash or of ash soluble in hydrochloric acid. In cases of adulteration one or other of these values is affected.—H. C. R.

Benzoic acid; Determination of —— in margarine. O. Köpke and E. Bodländer. Z. Unters. Nahr. Genussm., 1922, 43, 345—350.

50 G. of margarine and 100 c.c. of *N*/10 sodium bicarbonate solution are heated to 60° C. on a water bath in a stoppered flask and shaken for about 2 min. After cooling, 75 c.c. of the aqueous layer is poured off through a filter into a 100 c.c. measuring flask containing about 30 g. of pure ammonium sulphate and when the latter has dissolved, the solution is made up to the mark and again filtered. 80 c.c. of the filtrate is acidified with 3 c.c. of dilute sulphuric acid and extracted five times with 40 c.c. of a mixture of equal volumes of ether and of petroleum ether boiling under 60° C. The ethereal extract is washed three times with 5 c.c. of water to remove traces of sulphuric acid and the solvent evaporated off slowly on a water bath, the last fraction being removed at room temperature in a current of air. The residue is dissolved in water and titrated boiling with *N*/10 sodium hydroxide, using phenolphthalein as indicator; preferably a slight excess of *N*/10 sodium hydroxide is first added to prevent loss of benzoic acid and the solution titrated first with *N*/10 acid till the red colour disappears and then with *N*/10 alkali. The object of the addition of ammonium sulphate is to remove albuminous and other matter which would otherwise lead to the formation of emulsions. The percentage of benzoic acid is given by $a \times 0{\cdot}012208 \times (100 + {}^{w}/_{2})/30$ where a is the number of c.c. of *N*/10 sodium hydroxide used and w the percentage of water in the margarine. The reliability of this method was tested on a number of samples of margarine to which known amounts of benzoic acid had been added.
—H. C. R.

Carbolic acid [phenol]; Formation of —— during putrefaction. J. S. Maclaurin. Analyst, 1922, 47, 294—295.

Sheep's kidneys, both when inoculated with various cultures of organisms causing putrefaction and when untreated, developed phenol in amounts up to 0·028 g. per 100 g. after standing for periods of from 47 to 94 days at the ordinary summer temperature.

Utilisation of grain. Sorel. *See* XVIII.

Patents.

Bread; Manufacture of ——. W. Watson, D. W. Kent-Jones, and Woodlands, Ltd. E.P. 182,140, 4.3., 13.3. and 29.3.20.

Flour or dough before baking is incorporated with a small quantity of ammonium hydrogen sulphate and a small proportion of one or more "chlorine-carriers" such as chlorine, hydrochloric acid, ammonium chloride, magnesium chloride, the double chloride of ammonium and magnesium, a chlorate, perchlorate, or hypochlorite, with or without the addition of a pyrosulphate or persulphate. Advantages claimed are that a tough and resilient dough is more readily secured, and there is a considerable improvement in the baking qualities of the flour and in the colour of the resulting bread.—J. R.

Comestibles; Method of preserving ——. P. W. Petersen. U.S.P. (A) 1,420,739 and (B) 1,420,740, 27.6.22. Appl., (A) 28.2.21, (B) 6.10.21.

(A) Meat or other comestible is subjected to the direct action of a pre-cooling liquid substantially of the same osmotic pressure as the initial liquid content of the comestible, and is then subjected to a refrigerating operation. (B) The pre-cooling bath may be a mixture of glycerin and water or a solution of a crystalloid solute of the proper osmotic pressure.—J. R.

Vegetables; Process of treating —— in preparation for canning. W. W. Willison, Assr. to Thermo-kept Products Corp. U.S.P. 1,421,750, 4.7.22. Appl., 30.8.20.

The vegetables are subjected to the action of warm water under a partial vacuum subsequently suddenly released.—J. R.

Flour; Process for ageing wheaten —— to improve its baking qualities. R. Hutchinson. U.S.P. 1,422,102, 11.7.22. Appl., 19.3.21.

See E.P. 164,557 of 1920; J., 1921, 558 A.

Fish and the like; Apparatus for cooling and freezing ——. W. B. Hardy and J. J. Piqué. U.S.P. 1,422,570, 11.7.22. Appl., 12.10.20.

See E.P. 154,669 of 1919; J., 1921, 95 A.

Animal substances; Process of, and apparatus or *plant for, chilling and freezing ——.* J. C. Shaw. U.S.P. 1,422,627–8, 11.7.22. Appl., 5.9.18, and 11.3.20.

See E.P. 130,346 of 1917; J., 1919, 736 A.

Cooling and freezing fish and the like [; Apparatus for ——]. J. J. Piqué, and Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 182,214, 30.3.21. Addn. to 154,250 (J., 1921, 94 A).

XIXB.—WATER PURIFICATION; SANITATION.

Water; Precision in the determination of the hardness of ——, and aqueous preparation of the standard soap solution. E. Justin-Mueller. J. Pharm. Chim., 1922, 26, 18—21.

Clark's method as modified by Boutron and Boudet, is recommended, but a standard soap solution of only one-tenth the strength is used. It is prepared by disolving 3·5 g. of white Marseilles soap in 200 c.c. of boiling water and then making the volume up to 900 c.c. This solution is then diluted, if necessary, until 24 c.c. just corresponds to 40 c.c. of a 0·025% solution of calcium chloride or of a 0·059% solution of barium nitrate.—W. G.

Formation of phenol during putrefaction. Maclaurin. *See* XIXA.

Patents.

Sewage disposal. W. Gavett. U.S.P. 1,420,250, 20.6.22. Appl., 11.10.21.

The sewage during digestion is subjected to the pressure of gas generated by digestion in such a manner that the pressure removes the supernatant liquid from the sludge.—J. R.

Insecticide and method of making. H. H. Dow, Assr. to the Dow Chemical Co. U.S.P. 1,420,978, 27.6.22. Appl., 27.1.19.

An insecticidal mixture, prepared by the interaction of arsenic acid and excess of magnesium hydroxide, consists of a dry powder composed of di-magnesium ortho-arsenate admixed with about approximately one-fifth the amount of magnesium hydroxide.—J. R.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Strophanthus extracts; Stability of ——. C. A. Pome[illegible]y and F. W. Heyl. Amer. J. Pharm., 1922, [illegible]4, 479—486.

The decrease in potency of strophanthus extracts was studied using the American official one-hour frog test. Whilst the seeds themselves vary widely in strength, tinctures prepared from them retain their original therapeutic activity after long periods, and no appreciable decline was noticed after 4 or 5 years. Dilute aqueous galenical solutions prepared for hypodermic injection, containing both the crystalline and amorphous strophanthin deteriorate slowly and should be discarded after 1 year, when about 70% of the original activity is retained. Alkalinity or acidity of the solutions was not a factor in these results, as was suggested by Levy and Cullen (J. Exp. Med., 1920, 31, 267). Comparative tests were made on a 0·1% solution of ouabain in physiological salt solution, rendered neutral with buffer solutions of potassium acid phosphate and disodium hydrogen phosphate. It deteriorated to the extent of 86% of its original activity in 12 months.—G. F. M.

Alkaloidal mercuric iodides; Preparation of —— *in a crystalline condition.* M. François and L. G. Blanc. Comptes rend., 1922, 175, 169—171.

The amorphous precipitate obtained by adding potassium mercuric iodide to a solution of an alkaloidal salt can be brought into solution by warming it whilst suspended in the mother liquor with a large excess of hydrochloric acid; on then allowing to cool slowly it is usually re-deposited in a crystalline form. In the actual preparation of these crystals, the initial precipitation may be avoided by slowly mixing equal volumes of warm solutions of the alkaloidal salt containing a large amount of hydrochloric acid, and of potassium mercuric iodide, of suitable concentrations. A clear solution will be thus obtained from which the alkaloidal mercuric iodide is deposited in crystals on slowly cooling. In this way the mercuric iodides of caffeine, theobromine, quinine, morphine, codeine, cocaine, strychnine, pilocarpine, and sparteine, and also of quinoline, were prepared. They form brilliant yellow crystals, containing no chlorine and no water of crystallisation. They show a tendency, well marked in the case of the caffeine compound, but scarcely perceptible with the less soluble compounds, such as that of quinine, to be decomposed by water into mercuric iodide and the alkaloidal hydriodide.—G. F. M.

Samuela carnerosana, Trelease; Examination of the fruit of ——. O. F. Black and J. W. Kelly. Amer. J. Pharm., 1922, 94, 477—479.

The dried fruits of *Samuela carnerosana*, a tree closely related to the yuccas, and growing freely in parts of Mexico, consisted of about 30% of seeds and 70% of pods. From the ground seeds about 20% of their weight of a light yellow oil was obtained by extraction with ether. It had the following characters:—sp. gr. at 22° C., 0·9265; iodine value, 125·6; acid value, 5·13; n=1·4710; ester value, 187·7. A white amorphous saponin was obtained by extraction of the seeds with alcohol. It formed 10% of the seeds and was not highly toxic. The pods contained 4·8% of starch, 62·2% of reducing sugars (as dextrose), and 3·8% of non-reducing sugars (as sucrose). The reducing sugars appear to consist largely of lævulose. As about 50% of the dried fruit consists of fermentable sugars, it might be of value for the production of alcohol.—G. F. M.

Papain; Digestive properties of Philippine ——. H. C. Brill and R. E. Brown. Philippine J. Sci., 1922, 20, 185—193.

Autolysis of papain takes place in the course of a few hours at temperatures as low as 0° C. when the enzyme is kept in water solution with toluene as an antiseptic, and attempts to dialyse papain solutions in the hope of separating papain from any co-enzyme that might be present were unsuccessful. Air-dried samples of the enzyme in sealed glass containers had lost their activity at the end of seven years. The effect of mineral salts and certain acids on the digestive activity of papain on solutions of skimmed milk powder was studied. Sodium chloride showed first a slight activating effect, followed by an inhibiting effect in more concentrated solutions. Sodium carbonate and bicarbonate, calcium chloride, magnesium sulphate, and boric acid had no marked influence. Potassium chloride and sodium citrate showed marked activating influence, whilst acetic acid and lactic acid strongly inhibited the proteolytic activity.—G. F. M.

Autoxidation. Anti-oxygens, and various phenomena, related to anti-oxidising effects. C. Moureu and C. Dufraisse. Comptes rend., 1922, 175, 127—132. (*Cf.* J., 1922, 195 A.)

As previously recorded, the auto-oxidation of many substances is checked by the presence of traces of certain compounds, notably phenols, to which the name anti-oxygens was given. Quantitative experiments with acrolein have now been made to compare the inhibitive effect of proportions varying from 1 in 10 to 1 in 1,000,000 of various phenols on the rate of oxygen absorption. The measurements were made by observing the rate of ascension of the mercury column in barometer tubes, charged with the reagents, and comparing with a "blank" containing only acrolein and oxygen. Quinol was the most effective in suppressing auto-oxidation, as little as 1 in 100,000 having a very marked effect. Slightly less active were pyrogallol and catechol, followed by resorcinol and 1.3.4-trihydroxybenzene. At a concentration of 1 in 400 phloroglucinol has a maximum retarding effect, but at certain concentrations it actually accelerates oxidation. Attention is called to various well-known phenomena which may be attributed to anti-oxygens, *e.g.*, the action of sulphurous gases in preventing the luminescence of phosphorus in dilute oxygen, the action of benzyl alcohol, glycerol, phenol, etc. in retarding the oxidation of sulphite solutions, the prevention of the oxidation of synthetic caoutchouc by phenols, the improved keeping quality of essential oils in their natural condition, compared with that of the auto-oxidisable substances they contain when in a pure condition, etc.—G. F. M.

Saccharic and mucic acids; Methylation of ——. P. Karrer and J. Peyer. Helv. Chim. Acta, 1922, 5, 577—581.

Saccharic and mucic acids were methylated by treating with dimethyl sulphate in alkaline solution, freeing the incompletely methylated product from inorganic salts, and completing the methylation by boiling with methyl iodide in presence of silver oxide. Tetramethylsaccharic acid dimethyl ester crystallises from ether in stout needles or plates, m.p. 68° C., $[\alpha]_D^{18}=+8·88°$ to 10·26°. Tetramethylmucic acid dimethyl ester forms monoclinic or rhombic tables, m.p. 103°. An incompletely methylated mucate, m.p. 165°—166°, was isolated, probably trimethylmucic dimethyl ester. Tetramethylsaccharic diamide forms rhombic plates, m.p. 237°; $[\alpha]_D^{18}=+12·22$; tetramethylmucic diamide, small tabular crystals, m.p. 276°. The barium and silver salts of tetramethylsaccharic acid are very soluble in water.—E. H. R.

Methylenecitric acid; Preparation of ——. C. Gastaldi. Boll. Chim. Farm., 1922, **61**, 353—357.

A yield of methylenecitric acid equal to 74% of the theoretical amount is obtained when 40 grams of crystallised citric acid and 6 grams of paraformaldehyde are heated together at 145° C. in a sealed tube of 90 c.c. capacity; with a larger tube the yield is diminished.—T. H. P.

Urea; Industrial conversion of ammonia into ——. Fertiliser of high concentration. C. Matignon and M. Fréjacques. Chim. et Ind., 1922, **7**, 1057—1070. (*Cf.* J., 1922, 231 A.)

Ammonium carbamate is first prepared either by leading carbon dioxide into liquid ammonia, or by combining the two components, in the gaseous condition, in a special condenser with a suitable cooling device and scrapers. The dehydration to urea is effected in autoclaves at 145°—150° C., and an equilibrium is eventually attained as the result of the five reactions $CO(NH_2)ONH_4 \rightarrow CO(NH_2)_2 + H_2O$; $CO(NH_2)ONH_4 \rightarrow CO_2 + 2NH_3$; $CO(NH_2)ONH_4 + H_2O \rightarrow (NH_4)_2CO_3$; $(NH_4)_2CO_3 \rightarrow NH_4HCO_3 + NH_3$; $NH_4HCO_3 \rightarrow CO_2 + H_2O + NH_3$. Urea formation is favoured by making the gas volume as small as possible, and the attainment of equilibrium is more rapid the higher the temperature, but the pressure rapidly rises, the maximum at 135° C. being 33·14 atm., at 150° C. 55·10 atm. The equilibrium percentages of urea at various temperatures were determined: 130° C. after 39 hrs., 39·2%; 134° C., after 40 hrs., 39·92%; 140° C., after 40 hrs., 41·3%; 145° C., after 4 hrs., 41·0%; after 24 hrs., 43·3%. The higher temperature, therefore, increases also the actual yield, as a consequence of the endothermic nature of the reaction. The influence of catalysts was also studied. At the lower temperatures silica, aluminium silicate, and alumina considerably augment the velocity of the reaction, but at 145° C. their influence is negligible. The effect of dehydrating agents was unsatisfactory, as none could be found which did not also react with other substances in the equilibrium. From the reaction product, which is fluid at high temperatures, and solidifies at 70°—85° C., the urea was isolated in a pure state by simple volatilisation of the carbamate etc. present, and if, on a technical scale, the autoclave is allowed to cool to 60°—100° C., and the gases arising from the dissociation of the unchanged carbamate are then released, only urea remains in the vessel, or alternatively the operations may be made continuous by maintaining the autoclave at the desired reaction temperature, forcing in the requisite proportions of carbon dioxide and ammonia, at say 60 atm., into an annular compartment, and drawing off the fluid reaction product, after treating for the necessary period of time, through the central compartment into a second vessel where the unchanged carbamate volatilises.—G. F. M.

Nessler's reagent; New analytical applications of ——. Characterisation of ketones; estimation of aldehydes. J. Bougault and R. Gros. J. Pharm. Chim., 1922, **26**, 5—11.

Certain ketones, such as acetone, methyl ethyl ketone, cyclohexanone, trimethylcyclohexenone, acetophenone, and *p*-methoxyacetophenone, give with cold Nessler's reagent a yellowish-white precipitate, which dissolves in acid, or on the addition of potassium cyanide, with liberation of the ketone. This reaction may be used for the detection of acetone in urine, by suspending a small capsule, containing 10 c.c. of Nessler's reagent, over 200 c.c. of urine, previously acidified, the whole being covered by a bell jar. The time required for the formation of a precipitate varies inversely as the concentration of the acetone in the urine. Certain aldehydes react quantitatively with Nessler's reagent according to the equation,

$$R.CHO + H_2O + 2I = 2HI + R.CO_2H,$$

the iodine coming from the mercuric iodide. For the estimation, to a known volume of the aldehyde solution, corresponding to 0·01—0·05 g. of aldehyde, is added an excess (about 30 c.c.) of Nessler's reagent and 10 c.c. of sodium hydroxide solution. The mixture is well shaken and after some time is neutralised with hydrochloric acid. A known volume of standard iodine solution is added and then the excess iodine is titrated with standard thiosulphate. It is necessary to make a blank estimation on the sodium hydroxide. Accurate results were obtained with formaldehyde, benzaldehyde, furfural, and piperonal, but the method was not satisfactory for vanillin or acrolein.—W. G.

Acetic acid; Oxidation by chromic acid of the homologues of ——. L. J. Simon. Comptes rend., 1922, **175**, 167—169.

Whilst within certain limits of temperature acetic acid is unattacked by a mixture of sulphuric and chromic acids, it is completely converted into carbon dioxide by silver chromate under the same conditions. The homologues of acetic acid are likewise completely oxidised by silver chromate, but the chromic acid mixture leaves a non-oxidised residue, which for the homologues up to C_9 corresponds approximately to 1 C atom, and which increases slightly with the higher members but never reaches 2. This result is interpreted by supposing that the acids are oxidised atom by atom commencing with the carboxyl group, and the oxidation ceases when acetic acid is reached, thus:—

$$R.CH_2.CO_2H \rightarrow R.CO.CO_2H \rightarrow R.CO_2H + CO_2 \text{ etc.}$$

Confirmation of this hypothesis is found in the oxidation of acetyl compounds and acyclic acids by lead chromate and sulphuric acid, where the evolution of gas accompanying the oxidation occurs in two well-defined stages, viz., at a lower temperature corresponding to the more readily oxidisable part of the molecule, and at about 100° C. the temperature at which acetic acid is oxidised by lead chromate. Methanesulphonic acid is not an intermediate product of chromic oxidation, as it is not oxidised even by silver chromate.—G. F. M.

Terpene compounds; Higher ——. V. Conversion of abietic acid into methylretene. L. Ruzicka and J. Meyer. Helv. Chim. Acta, 1922, **5**, 581—593.

Abietic acid, $C_{20}H_{30}O_2$, when heated with sulphur is converted into retene, 1-methyl-7-isopropylphenanthrene. The methyl ester, dihydroabietic acid, and the corresponding alcohol, abietinol,

$$C_{18}H_{26}(CH_3)CH_2OH,$$

also give retene when similarly treated. When abietinol is dehydrated with phosphorus pentachloride it gives a new hydrocarbon, methylabietin, $C_{20}H_{30}$, which, when heated with sulphur, gives methylretene, m.p. 79° C. When oxidised with chromic acid, this gives methylretenequinone, m.p. 147°, giving with *o*-phenylenediamine a quinoxaline, m.p. 165°. Abietic acid is a methyldecahydroretenecarboxylic acid, but the orientation of the methyl and carboxyl groups is uncertain. Retene styphnate has m.p. 142°. (*Cf.* J.C.S., Sept.)
—E. H. R.

Essential oil from the leaves of Abies Pindrow, Spach. J. L. Simonsen. Indian Forest Rec., 1922, **8**, 368—372.

The essential oil was produced in 2·5% yield by the steam distillation of the leaves of *Abies Pindrow*, a silver fir growing in the Western Himalayas. It is a colourless oil with a strong odour of turpentine, and has the following characters:—sp. gr. at 30°/30° C. 0·8558,

saponif. value 5·3, saponif. value after acetylation 15·44, acid value 0·3. It gave on distillation under 100 mm. pressure 90% up to 120° C., and on fractionation of this at 699 mm. pressure the following fractions were isolated: 154°—158° C. 55·9%, consisting of *d*-*α*-pinene, 158°—160° C. 11·9%, consisting of a mixture of *α*- and *β*-pinene, 160°—164° C. 6·8%, consisting of a similar mixture, 164°—167° C. 4·2%, containing *l*-*β*-pinene, 167°—180° C., 10·3%, containing *l*-limonene, and possibly dipentene, and above 180° C. 10·6 %, from which, together with the fraction boiling above 120° C. at 100 mm., *l*-terpineol, *l*-terpinyl nonylate, and two isomeric sesquiterpene alcohols, $C_{15}H_{24}O$, were isolated.
—G. F. M.

Sandalwood oil; Abnormal solubility of West Australian —— in alcohol. J. L. Somerville. Perf. Essent. Oil Rec., 1922, **13**, 261—264.

West Australian sandalwood oil shows an abnormal type of miscibility with alcohol-water mixtures: when a concentrated solution of oil is diluted with the solvent, oil separates again after the dilution has passed a certain limit. The solubility of the oil is expressed by means of a curve for each strength of alcohol (68—72%), the transition points being plotted against temperature and percentage of oil. A series of similar U-shaped curves is thus obtained, the apex of each occurring at approximately 16·5% of oil. A more fundamental graphing was made by calculating the data into percentages by weight of the three constituents, oil, alcohol, and water, and plotting the transition points for a given temperature. No explanation can be given of the abnormal behaviour, but it follows from the latter graph that a simple statement of the facts is that, at a constant temperature, in a series of mixtures which are just miscible, if the amount of oil is lowered the proportion of water to alcohol present will need to rise at first until a turning point is reached, and then it will need to fall with further decrease in the proportion of oil.
—G. F. M.

Doryphora sassafras (Endlicher); Essential oil of the leaves of ——. A. R. Penfold. Perf. Essent. Oil Rec., 1922, **13**, 273—275.

The leaves of *Doryphora sassafras*, the New South Wales variety of the sassafras tree, yield according to season 0·1—1·05% of essential oil, the former quantity being obtained in May and the latter in November. The oil varies considerably in composition according to the districts from which it is obtained. Leaves from the Monga district gave an oil having the characters: sp. gr. 1·01—1·02, n=1·506—1·509, ester value 4·6, ester value after acetylation 32·97, solubility in 70% alcohol 1 in 8. The principal constituents so far identified are safrole 60—65%, camphor 10—15%, *d*-*α*-pinene 10%, sesquiterpenes 10%, eugenol 1%. Another sample of oil from the Currowan district was lighter than water (sp. gr. 0·9808), and only contained about 30% of safrole, together with a considerable quantity of a substance which was apparently eugenol methyl ether, but which has not yet been satisfactorily separated from admixed sesquiterpenes and alcoholic compounds. The proportion of camphor in this oil was also greater, amounting to about 30%.—G. F. M.

Volatile oil of Mentha aquatica, Linné, and a note on the occurrence of pulegone. R. E. Kremers. J. Biol. Chem., 1922, **52**, 439—443.

The distilled oil of *Mentha aquatica*, Linné, has sp. gr. 0·916 at 24° C., $n^{24}=1·4582$, $[\alpha]_D^{24}=-7·48°$, acid value 7·84, ester value 210·93, ester value after acetylation 224·0, and contains 73·82% of esters, 61·6% of total alcohols, 3·6% of free alcohols. The esters consist mainly of linalyl acetate. There are also present small quantities of another ester, free linalool, a free acid, and an unstable aldehyde. Pulegone is a constituent of the cohobated oil of peppermint (*cf.* J., 1922, 269 A).—E. S.

Patents.

Amino-nitro-compounds; Preparation of aromatic ——. Soc. Chim. de la Grande Paroisse. E.P. 169,658, 12.8.21. Conv., 30.9.20.

Instead of using alcoholic ammonia and operating in an autoclave, the replacement of chlorine atoms by the amino group in chloro-nitro-derivatives may be effected at 125°—130° C. in open vessels by treating with ammonium acetate. This process is applicable to all aromatic chloro-nitro-compounds in which the chlorine is capable of being acted on by ammonia. *Example*: 120 kg. of 80—95% acetic acid is saturated with ammonia gas. The temperature rises to 125°—130° C. and 100 kg. of 1-chloro-2.4-dinitrobenzene is gradually added, ammonia being continuously passed through to replace that which has entered into the reaction. After some hours the product is filtered and pressed, the liquid being returned to the process. Quantitative yields are obtained and the product is purified by simple washing.—G. F. M.

Phosphoric acid; Manufacture of liquid esters of ——. A. G. Bloxam. From Chem. Fabr. Griesheim-Elektron. E.P. 181,835, 22.3.21.

Liquid esters of phosphoric acid are made by forming mixed esters from phenol and its homologues, or from its homologues alone, the parent materials used being either artificial mixtures of phenols, containing at least 25—30% of *o*- or *m*-cresol, or the tar acids, either as a whole, or fractions therefrom, containing mixed monohydric phenols with at least 25% of *o*- or *m*-cresol, obtained from coke-oven, gas works, or other tars. The esters are obtained by heating the mixed phenols with phosphorus oxychloride, or phosphoric anhydride, or alternatively the phosphoric di- or mono-chlorides may be prepared from single phenols, and then converted into neutral esters with another phenol or mixture of phenols. Examples are given of the preparation of a large variety of these mixed esters, and also of certain individual mixed esters, prepared by the latter of the above described methods, as for example *p*-cresyl-di-*m*-cresyl phosphate, a fluorescent oil, b.p. 287°—289° C. at 21 mm., and *o*-cresyl-diphenyl phosphate, b.p. 290°—293° C. at 55 mm.—G. F. M.

Urea; Manufacture of ——. J. Y. Johnson. From Badische Anilin- und Soda-Fabrik. E.P. 182,331, 11.7.21.

In the manufacture of urea by heating ammonia and carbon dioxide (or ammonium carbamate) under pressure, the use of pumps etc. for compressing the gases may be avoided by bringing either the ammonia or carbon dioxide or both to the pressure required for the reaction, either separately or simultaneously, by expelling either or both of them under pressure from suitable solutions by means of heat. For example a highly concentrated solution of ammonium carbonate or carbamate is heated by steam at 180 lb. pressure in a column, whereby a gas mixture comprising ammonia, carbon dioxide, and some water vapour is obtained under pressure and is passed through a cooler kept at a temperature (110°—150° C.) high enough to allow condensation of a melt of ammonium carbonate but no solidification. The melt is then run into the autoclave for conversion into urea, and the mixture of ammonia and carbon dioxide remaining unchanged after equilibrium has been attained is used for the re-saturation of the exhausted liquid running from the column. Instead of generating ammonia and carbon dioxide together, they may be distilled separately, for example by heating in separate columns aqueous ammonia and sodium bicarbonate solutions, or, if desired, one of the two gases may be forced into the autoclave by means of a compressor.—G. F. M.

Acetyl isoborneol; Process of making ——. R. L. Andreau, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,420,399, 20.6.22. Appl., 7.7.17.

Acetylisoborneol is obtained by heating camphene with acetic acid in presence of concentrated sulphuric acid at 55°—66° C., until the reaction is practically completed. The sulphuric acid is then neutralised with anhydrous sodium acetate, the resulting acetic acid is distilled off under reduced pressure, and the sodium sulphate formed by the neutralisation filtered off from the residue. —G. F. M.

Esters; Manufacture of ——. J. A. Steffens, Assr. to U.S. Industrial Alcohol Co. U.S.P. (A) 1,421,604 and (B) 1,421,605, 4.7.22. Appl., 5.4.21.

(A) Esters are produced by heating together an alcohol and an acid, without a catalyst, but in presence of a third liquid, miscible with the alcohol, but immiscible with water, the vapours of water, the alcohol, and the third liquid being distilled from the reaction mixture and rectified, and the distillate separated into two layers containing respectively high and low percentages of the third liquid. The latter is washed to remove the third liquid, and the remainder containing water and the alcohol is rectified. (B) The process is similar to the above, except that a catalyst is used in addition to the third liquid.—G. F. M.

Ethylene; Process of producing ——. M. C. Whitaker and A. A. Backhaus, Assrs. to U.S. Industrial Alcohol Co. U.S.P. 1,421,640, 4.7.22. Appl., 11.7.19.

Alcohol is preheated to a temperature of 300°—500° C., and the resulting vapours are passed through a catalyst maintained at a similar temperature in order to form ethylene.—G. F. M.

Hydroquinone [quinol]; Process of making ——. H. Von Bramer, Assr. to Eastman Kodak Co. U.S.P. 1,421,869, 4.7.22. Appl., 28.6.20.

In the manufacture of quinol a *p*-dihalogenbenzenesulphonate is treated with a metal hydroxide, producing the quinol salt of the metal, and quinol is recovered from the reaction mixture.—W. C.

Dichlorethylene; Manufacture of ——. F. Kaufler, Assr. to A. Wacker. Ges. f. Elektrochem. Ind. m.b.H. U.S.P. 1,419,969, 20.6.22. Appl., 18.7.21

See E.P. 156,080 of 1920; J., 1921, 411 A.

Tropinone-monocarboxylic-acid esters and process of preparing the same. O. Wolfes and H. Maeder. U.S.P. 1,420,900, 27.6.22. Appl., 26.8.21.

See E.P. 164,757 of 1921; J., 1922, 436 A.

Diphenylamine; Method of manufacturing ——. A. P. Tanberg, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,422,494, 11.7.22. Appl., 31.5.17.

See E.P. 138,372 of 1917; J., 1920, 280 A.

Apparatus for effecting reactions by means of amalgams. Electrolytic reduction and oxidation. Manufacture of oxalate. U.S.P. 1,420,211—3. *See* VII.

Methyl chloride. U.S.P. 1,421,733. *See* VII.

Electrochemical reactions. E.P. 181,848—9. *See* XI.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Colour-sensitising [of photographic plates] by bathing. F. M. Walters, jun., and R. Davis. Brit. J. Phot., 1922, **69**, 416—419 and 430—433.

An investigation of the methods of sensitising ordinary photographic plates by bathing shows that certain precautions must be taken with some of the modern photo-sensitising dyes and not with others. Dicyanine gives much greater sensitiveness, and its influence extends farther into the infra-red when used in dilute alcoholic solution with ammonia than when used with water alone. Pinacyanol gives good results in dilute alcoholic solution with ammonia, but plates bathed in water and stock solution are almost as sensitive and keep much better, provided the plates are thoroughly washed before sensitising, as the soluble salts contained in the emulsion prevent the sensitising action by flocculating the dye. Washing has a favourable action on the colour sensitiveness of panchromatic plates, and, while not so marked as the action of dilute ammonia, it gives no fog, which always follows the use of ammonia. Pinachrome, Pinaverdol, Homocol, and Orthochrome T are much less sensitive to electrolytes than are Pinacyanol and Dicyanine. Ammonia may be added to a staining bath of water and stock solution only, but does not increase the sensitising action appreciably except in the case of Homocol. Certain brands of orthochromatic plates were found to be superior to plates bathed in Erythrosin. As a general rule panchromatic plates compare unfavourably with plates bathed in Pinacyanol.—W. C.

[Photographic] toning with tin salts. J. G. F. Druce. Brit. J. Phot., 1922, **69**, 433—434.

Bromide prints may be toned to a warm brown tint by first bleaching them in a solution of ferricyanide, and then treating them in a bath of sodium hydrogen stannite made up by adding a 10% solution of sodium hydroxide to a 10% solution of stannous chloride crystals until the precipitate first formed is redissolved. The resulting solution is then diluted with rather less than an equal quantity of water. The toned image is stated to consist of silver.—W. C.

Photographic plates; Removal of the film from ——. F. Limmer. Chem.-Zeit., 1922, **46**, 651—652.

The gelatin film may be removed from photographic plates by immersing them for a few seconds in a 1—2% solution of ammonium bifluoride. The film readily peels away, and may be removed from the solution intact and dried, while the glass plate, after washing and drying, may be used again. 200 c.c. of the stripping solution is sufficient for at least 150 plates, 9 cm. × 12 cm. The method is not suitable for films.—A. R. P.

Patents.

Photographs; Process for producing opaque —— *in natural colours.* M. Obergassner. E.P. 182,167, 21.3.21.

A colloidal three-colour screen is employed containing in part dyes which become colourless on treatment with acids or alkalis, or by neutralisation, oxidation, or reduction, and in part colourless substances which become coloured by such treatment. The colloid used for producing the colour screens may be mixed with a substance, *e.g.*, barium chloride, which is precipitated to form an insoluble combination with the dye in order to increase the vigour of the colours. A modified screen may be used which consists of a colloid medium containing colourless diazo- or nitroso-salts which are converted into dyes by suitable treatment, which renders colourless the original screen colours.—W. C.

Light-diffusing medium and method of making the same. L. W. Eberlin and S. E. Sheppard, Assrs. to Eastman Kodak Co. U.S.P. 1,421,924, 4.7.22. Appl., 13.12.20.

The composition consists of a mixture of a water-soluble silicate and amylaceous particles.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Explosive composition. L. O. Bryan, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,420,364, 20.6.22. Appl., 6.1.22.

An explosive composition consists of more than 25% of nitrocellulose, 1—10% of a liquid explosive, and 0·3—5% of powdered aluminium.—J. R.

High-explosive containers; Method of filling ——. J. P. Madden and L. Fisher, Assrs. to Bethlehem Steel Co. U.S.P. 1,420,637, 27.6.22. Appl., 3.6.21.

A quantity (*e.g.*, 3 pts.) of trinitrotoluene is melted and mixed with a quantity (*e.g.*, 7 pts.) of dry trinitrotoluene sufficient to form a plastic mass, which is packed in the shell or container.—J. R.

Perchlorate explosives; Manufacture of ——. C. Bunge. G.P. 350,563, 31.12.19. Addn. to 303,289 (J., 1920, 208 A).

Mixed crystals containing potassium chlorate, ammonium chlorate, and potassium permanganate, or ammonium chlorate and potassium chlorate, or ammonium chlorate and potassium permanganate, are added to perchlorate explosives instead of the mixed crystals described in the chief patent.
—L. A. C.

XXIII.—ANALYSIS.

Buffer values; Measurement of —— and the relationship of buffer value to the dissociation constant of the buffer and the concentration and reaction of the buffer solution. D. D. Van Slyke. J. Biol. Chem., 1922, 52, 525—570.

A theoretical paper, the object of which is to give quantitative expression to buffer effects. For this purpose, the buffer value, β, of a solution is defined as the number of g.-equivalents of strong alkali or acid which must be added (strictly without change of volume) to one litre to produce unit change in p_H. Formulated mathematically, $\beta = dB/dp_H$ (*cf.* Koppel and Spiro, Biochem. Zeits., 1914, 65, 409, who have given a somewhat similar definition). An increment of strong acid is regarded as a negative increment of strong base; hence the value of β is always positive. Starting from the laws of ionic mass reaction, the following general equation for buffer value has been deduced:

$$\beta = 2{\cdot}3\{(K'[H^{\cdot}]C)/(K'+[H^{\cdot}])^2 + [H^{\cdot}] + [OH']\}$$

in which K′ represents either K_a/γ_s or $K_W\gamma_s/K_b$ according as the buffer is a weak acid or a weak base, and C = the molecular concentration of buffer acid (or base). When the p_H is between 3 and 11 and C is not much less than 0·1 N, $[H^{\cdot}]$ and $[OH']$ may be neglected and the equation simplifies to $\beta = 2{\cdot}3K'[H^{\cdot}]C/(K'+[H^{\cdot}])^2$, an expression which has also been deduced directly from Henderson's equation: $K_a = [H^{\cdot}]\gamma_s[Ba]/[Ha]$ (Amer. J. Physiol., 1908, 21, 169; Ergbn. Physiol., 1909, 8, 254). Under these conditions

$$\beta/C(=\beta_M) = 2{\cdot}3K'[H^{\cdot}]/(K'+[H^{\cdot}])^2,$$

β_M being termed the molecular buffer value of the buffer acid or base. By differentiation of the last equation it is shown that the maximum value of β_M occurs when $[H^{\cdot}] = K'$, and it follows that at this point $\beta_M = 2{\cdot}3/4 = 0{\cdot}575$ for all buffers. Further, when $K' = [H^{\cdot}]$, $[Ha] = [Ba]$; hence at the maximum molecular buffer value half the buffer acid (or base) is present in the free state and half in the form of salt. The above methods have been extended to the calculation of β for solutions of polyvalent, amphoteric, and mixed buffers.—E. S.

Colorimetric and electrometric determinations of hydrogen ion concentrations in solutions containing carbon dioxide; Comparison of ——. G. E. Cullen and A. B. Hastings. J. Biol. Chem., 1922, 52, 517—520.

Contrary to the results obtained by Evans (J. Physiol., 1921, 54, 353), the colorimetric and electrometric methods for the estimation of the hydrogen-ion concentration of solutions containing carbon dioxide yield identical results provided precautions are taken to prevent the loss of carbon dioxide.—E. S.

Modification of the Clark hydrogen electrode vessel to permit accurate temperature control. G. E. Cullen. J. Biol. Chem., 1922, 52, 521—524.

The Clark electrode vessel (J. Biol. Chem., 1915, 23, 475) is provided with an additional opening by means of which a thermometer may be inserted in the solution.—E. S.

Estimation of potassium in the presence of sodium, magnesium, sulphates and phosphates; Investigation of Atkinson's process for the ——. S. J. Watson. Analyst, 1922, 47, 285—288.

The process (J., 1921, 751 A) is considered unsatisfactory because the compensating errors necessary to overcome the loss due to the solution of some potassium perchlorate do not occur to an extent sufficient to balance this loss, and the quantity of methyl alcohol and perchloric acid used is too large to make the process economical. Keeping the contents of the beaker at the boiling point for an hour, whilst perhaps necessary to ensure complete solution of undesirable substances, must also favour the solution of potassium perchlorate itself.—H. C. R.

Magnesium; Colorimetric method for the determination of small amounts of ——. A. P. Briggs. J. Biol. Chem., 1922, 52, 349—355.

The method described is similar to that of Hammett and Adams (*cf.* J., 1922, 612 A).—E. S.

Electrometric titrations with silver nitrate. Determination of chlorides, iodides, and bromides, and of iodides in the presence of chlorides and bromides. I. M. Kolthoff. Z. anal. Chem., 1922, 61, 229—240.

In the titration of chlorides, iodides, and bromides with silver nitrate solution the end-point may be determined electrometrically; the method is particularly useful in the case of coloured and very dilute solutions. In ammoniacal solution, iodides may be titrated in the presence of large quantities of chlorides and small amounts of bromides. The method is also trustworthy for the determination of ferricyanides, thiocyanates, cyanides, oxalates, chromates, tartrates, succinates, and salicylates, but not of ferrocyanides and pyrophosphates.
—W. P. S.

Oxalic acid; Detection and determination of —— and its use in standardising iodine and silver solutions. L. Rosenthaler. Z. anal. Chem., 1922, 61, 219—222.

When potassium iodate solution is heated with the addition of a small quantity of oxalic acid, iodine is liberated; the reaction may be obtained with as little as 3 mg. of oxalic acid. Tartaric and malic acids also liberate iodine from potassium iodate, but so slowly that their presence does not interfere with the reaction obtained with oxalic acid. The reaction serves for the determination of oxalic acid and oxalates; a portion of the sample is heated with a known amount in excess of potassium iodate solution in the presence of dilute sulphuric acid until all liberated iodine has been expelled. The mixture is then cooled, potassium iodide is added, and the iodine liberated from the excess of iodate used is titrated with thiosulphate solution. Pure sodium oxalate may be used in the standardisation of iodine solution and silver nitrate solution; for the latter, a known quantity of the oxalate is treated with a slight excess of the silver nitrate solution, the mixture is diluted to a definite volume, filtered, and the excess of silver in the filtrate titrated with thiocyanate solution.—W. P. S.

Arsenic and antimony sulphides; Iodometric determination of ——. F. Nikolai. Z. anal. Chem., 1922, **61**, 257—272.

The method proposed consists in dissolving the arsenic trisulphide, or antimony trisulphide, in sodium hydroxide solution, adding this solution to an excess of standard iodine solution containing dilute acetic acid and sodium acetate, and then titrating the excess of iodine in the acid solution with thiosulphate solution. Oxidation of the alkaline sulphide solution by atmospheric oxygen may be prevented or retarded considerably by the addition of a small quantity of gelatin. The use of iodine solution containing acetic acid and sodium acetate is also recommended for the determination of arsenites and the corresponding antimony compounds; the arsenite solution is added to an excess of the iodine solution and the excess then titrated with thiosulphate solution.—W. P. S.

Arsenic acid; Determination of ——. L. Rosenthaler. Z. anal. Chem., 1922, **61**, 222—229.

In the iodometric determination of arsenic acid atmospheric oxygen is liable to react with the hydriodic acid formed and yield further quantities of iodine, but this may be prevented by adding sodium bicarbonate (to furnish an atmosphere of carbon dioxide) before the potassium iodide is introduced. At least 16% of hydrochloric acid or 33·3% of sulphuric acid should be present in the solution to be titrated, otherwise the reaction is not quantitative. When sulphuric acid is used, the solution, after the addition of the requisite quantity of the acid, is cooled, 5 g. of sodium bicarbonate is added, followed by concentrated potassium iodide solution, and the mixture is then titrated with thiosulphate solution. A precipitate, consisting mainly of arsenic tri-iodide, may form on the addition of the iodide; this precipitate should be dissolved by adding a small quantity of water before the titration is commenced.—W. P. S.

Carbon dioxide indicator for flue gases; Automatic ——. R. B. MacMullin. J. Ind. Eng. Chem., 1922, **14**, 628—629.

A simple apparatus that can be made with bottles and glass tubing and contained in a wooden case, 8″×20″×20″, is described and illustrated. By means of it the continuous automatic analysis of flue gas for carbon dioxide can be carried out to an accuracy of 0·2%. The apparatus depends on the difference in rate of flow of the gas through a capillary tube according to the percentage of carbon dioxide it contains, the pressure drop and rate of flow of the gases, after absorption of carbon dioxide, through another capillary tube being kept constant.
—H. C. R.

Methane; Determination of small quantities of ——. [*Absorption of carbon dioxide.*] E. Murmann. Oesterr. Chem.-Zeit., 1922, **25**, 90.

The complete absorption in baryta solution of small quantities of carbon dioxide, obtained for example in the determination of traces of methane by combustion has hitherto required two or three absorption flasks in series, owing to the short time the bubbles are in contact with the liquid. One ordinary Erlenmeyer flask is sufficient, however, if the gas is led into the baryta solution through a capillary tube, and 0·5—1·0 c.c. of 1% gelatin solution is added to the liquid so as to produce a foam on the surface which increases the duration of contact of the gas and liquid to at least 30 secs., and thereby renders absorption complete. The capillary tube may conveniently be fixed into the flask through the straight arm of a T-piece, fitted into the neck of the flask with a rubber stopper, and the connexion made gas-tight with a short piece of rubber tube. The device may also be useful in other cases of gas absorption.
—G. F. M.

Nitrate nitrogen in urine etc.; Detection and determination of ——. O. Nolte. Z. anal. Chem., 1922, **61**, 278—282.

Nitrates may be detected in urine etc. by means of the diphenylamine test and the less sensitive ferrous sulphate test; attention is directed to the fact that the diphenylamine test is not characteristic of nitrates, since the reaction is also given by other oxidising substances. The Schlösing-Grandeau gasometric method is the most trustworthy for the determination of the nitrate, but the actual nitric oxide content of the gas evolved must be determined, since small quantities of nitrogen are sometimes present.—W. P. S.

PATENTS.

Gas; Method of, and apparatus for detecting the presence of one —— in another. C. H. M. Roberts. U.S.P. 1,421,720, 4.7.22. Appl., 3.6.20.

The presence of one gas in another is detected by passing the mixture to be tested between opposed spaced electrodes connected with a suitable source of low voltage direct current electricity. The amount of current passing across the gap is measured by suitable means, and it varies with the amount of the gas to be detected which is present in the mixture.—G. F. M.

Gas-analysing apparatus. O. Rodhe, Assr. to Aktiebolaget Ingeniörsfirma F. Egnell. Reissue 15,409, 11.7.22. of U.S.P. 1,302,224, 29.4.19. Appl., 3.3.22.

See E.P. 103,812 of 1916; J., 1918, 447 A.

Patent List

The dates given in this list are, in the case of Applications for Patents, those of application and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Aktiebolaget Ljungströms Angturbin. Air-cooled condensers. 20,604. July 27. (Sweden, Apr. 22.)

Aktiebolaget Ljungströms Angturbin. Regenerative air-preheaters. 20,605. July 27. (Sweden, May 8.)

Aktiebolaget Separator. Cleaning bowls of centrifugal separators. 21,028. Aug. 1. (Sweden, 22.9.21.)

Babcock and Wilcox, Ltd. (Deutsche Babcock & Wilcox Dampfkessel-Werke A.-G.) Furnaces. 21,507. Aug. 8.

Bailey. Apparatus for metering granular material. 20,377. July 25. (U.S., 23.9.21.)

Barnes and Fleming. Grinding-mills. 20,523. July 27.

Bicknell and Honeysett. Means for mixing and treating liquids. 20,696. July 28.

Brandon. Dephlegmators. 21,042. Aug. 1.

Brandon. Apparatus for preheating or vaporising liquids. 21,043. Aug. 1.

Brims. Combination dry and steam heating apparatus. 21,589. Aug. 8.

Broquier y Gautier. Refrigerating-apparatus. 21,345. Aug. 4. (Spain, 5.8.21.)

Bullock, and Sandycroft, Ltd. Crushing-machines. 21,148. Aug. 2.

Christiani. Method for accumulation of heat by means of disintegrated masses. 21,545. Aug. 8. (Germany, 9.8.21.)

Coppée et Cie. Combined washing and sorting apparatus. 20,898. July 31. (Belgium, 1.8.21.)

De Fonblanque and Moeller. Method for producing superheated steam, gases, or air. 21,063. Aug. 2.

Duckham, and Woodall, Duckham and Jones (1920), Ltd. Heating materials. 20,723. July 28.

Grange Iron Co., Ltd., and Hoyle. Centrifugal separators. 21,600. Aug. 8.

Griffin. 20,289. *See* II.

Hamble. Filter. 21,080. Aug. 2.

Hesselman. Liquid-filters. 21,710. Aug. 9. (Sweden, 31.8.21.)

Hider. 21,128. *See* XIX.

Humble. Filtering-device. 21,984. Aug. 12.

Jerrard. Refrigerating-machines and condensing apparatus. 21,663. Aug. 9.

Lake (Tate). Delivering liquids in gaseous condition. 20,248. July 24.

Lea. Apparatus for measuring granular etc. materials. 20,656. 20,665. July 28.

Lehmann Co., Inc. Apparatus for treating finely-divided material. 21,696. Aug. 9. (U.S., June 14.)

Lodge-Cottrell, Ltd., and Lodge. 21,588. *See* XI.

McIntosh and Viccars. Refrigerating-apparatus. 20,646. July 28.

Mangiameli. Obtaining mixture of gases in any desired volumetric proportions. 20,302. July 25. (Germany, 25.7.21.)

Marcotte. Process for utilisation of luminescent and catalytic substances. 21,824. Aug. 10. (France, 13.8.21.)

Marks (Bock Bearing Co.). Grinding-machines. 20,355. July 25.

Metropolitan-Vickers Electrical Co., Ltd. (Westinghouse Electric and Mfg. Co.). Steam-condensing plant. 21,355. 21,356. Aug. 4.

Portas. Grinding etc. mills. 21,000. Aug. 1.

Reid. Steam heating-apparatus. 20,245. July 24.

Sainsbury. Means for removing moisture from materials in grinding and sifting machines. 20,220. July 24.

Sauer. Process for treating liquids. 20,168, July 24. 21,645, Aug. 9. (Germany, 23.7.21, 9.8.21.)

Vulkan-Werk Reinshagen & Co. Furnaces. 21,720. Aug. 9. (Germany, 9.8.21.)

Weight. Method of refrigeration. 20,510. July 27.

Complete Specifications Accepted.

6309 and 13,151 (1921). Reid. Furnaces. (183,508.) Aug. 10.

10,197 (1921). Barrs. Cooling-, condensing-, or heating-apparatus. (183,195.) Aug. 2.

10,963 (1921). Leubli. Grinding-mills. (183,215.) Aug. 2.

11,057 (1921). Morison. Heating and deaerating of liquids. (183,534.) Aug. 10.

11,321 (1921). Chaudière. Shaft furnaces and the like. (161,971.) Aug. 2.

11,466 (1921). Case. Method of and means for treating air. (183,544.) Aug. 10.

11,554 (1921). Aktiebolaget Ljungströms Angturbin. Apparatus for effecting the transfer of heat between liquids and gases. (162,250.) Aug. 10.

11,597 (1921). Lamplough. Generating and superheating of steam. (183,261.) Aug. 2.

12,139 (1921). Fothergill. Steam-condensing plant. (183,271.) Aug. 2.

12,315 and 16,997 (1921). Cooke and Croxon. Apparatus for superheating or preheating fluids. (183,918.) Aug. 16.

16,401 (1921). Erickson. Furnaces. (183,666.) Aug. 10.

19,498 (1921). Webster. Retorts or furnaces. (184,040.) Aug. 16.

19,960 (1921). Perrett. Means for adding reagents to liquids. (183,357.) Aug. 2.

20,062 (1921). Fletcher. Means for separating solids of different specific gravities. (184,049.) Aug. 16.

21,816 (1921). Rigby. Scale-removing composition for boilers. (183,371.) Aug. 2.

25,713 (1921). Hoogbruin, and Naaml. Vennoots. Fabriek van Stoom-en andere Werktuigen Jonker & Zoon. Boilers for heating liquids and generating steam or vapour. (184,092.) Aug. 16.

30,625 (1921). Lodge Fume Co., Ltd. (Möller). *See* XI.

33,202 (1921). McIntyre. Grinding, refining, and mixing machines. (183,399.) Aug. 2.

3770 (1922). Beth. Filter-bag cleaning-devices for air-filters. (175,281.) Aug. 16.

11,787 (1922). Accioly. Filters. (183,784.) Aug. 9.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Babin. Gas-generators. 20,803. July 29. (France, 30.7.21.)

Brandes. Production of coke from inferior fuel. 21,154. Aug. 2.

Brandes. Utilisation of peat etc. 21,015. Aug. 1.

Byrnes. Manufacture of liquid fuel. 21,046. Aug. 1.

Chilowsky. Atomising and gasifying heavy combustibles for internal-combustion engines, furnaces, etc. 20,231. July 24. (France, 27.7.21.)

Consortium für Elektrochem. Ind. Ges. Process for purifying acetylene. 21,051. Aug. 1. (Germany, 1.8.21.)

Davidson. 20,384. *See* XXIII.

De Fonblanque and Moeller. Method of treating peat etc. 21,062. Aug. 2.

De Fonblanque and Moeller. Treatment of peat. 21,462. Aug. 5.

Duckham, and Woodall, Duckham and Jones (1920), Ltd. Method of briquetting fuel. 20,827. July 29.

Erdöl- und Kohle-Verwertung A.-G., and Erlenbach. Process for catalytic cracking of hydrocarbon oils, tars, etc. 21,048. Aug. 1.

Esling. Sweating paraffin etc. waxes. 20,465. July 26.

Gibson and Nicoll. Apparatus for charging furnaces of gas retorts etc. 21,317. Aug. 4.

Griffin. Machine for pulverising coal etc. 20,289. July 25.

Hay. Separating water from coal. 21,871. Aug. 11.

Hiller. Production of charcoal. 21,280. Aug. 3.

Illingworth. Treatment of shale, coal, etc. for removal of sulphur. 21,011. Aug. 1.

Kilburn (Sulzer Frères). Cooling incandescent coke. 21,099. Aug 2.

Macdonald. 20,990. *See* XXIII.

Perry. Apparatus for distilling carbonaceous material. 21,010. Aug. 1.

Rigby. Treatment of peat etc. 20,561. July 27.

Ritte. Production of producer gas for propelling vehicles. 20,482. July 26.

White. Low-temperature carbonisation of coal etc. 21,582. Aug. 8.

Complete Specifications Accepted.

2510 (1921). Davies. Apparatus for use in cooling, cleansing, or scrubbing gases in connection with all types of gas producers. (183,160.) Aug. 2.

5967 (1921). Jones, and Minerals Separation, Ltd. Concentration of coal. (183,504.) Aug. 10.

7712 (1921). Optische Anstalt Goerz A.-G., and Gehlhoff. Electric arc lamps. (183,179.) Aug. 2.

7883 (1921). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and Morgan. Treatment of peat and the like. (183,180.) Aug. 2.

7897 (1921). Marks (Stephens Engineering Co.). Combustion of fuel. (183,512.) Aug 10.

8883 (1921). Colebrooke and Williams. Renewal of the filaments in metal-filament electric lamps. (183,523.) Aug. 10.

9157 and 16,387 (1921). Nesfield. Means for desulphurising oils. (183,527.) Aug 10.

10,831 (1921). Trent Process Corp. Distillation of oils. (171,075.) Aug. 2.

10,919 (1921). Glawe. Method of mixing briquette-forming materials with a fluid binding-agent. (183,212.) Aug. 2.

11,065 (1921). Ferolite, Ltd., and Clapp. Gas-producers, electric furnaces, crucible furnaces, and the like. (183,219.) Aug. 2.

11,134 (1921). Burton. Gas-retort mouthpieces. (183,225.) Aug. 2.

11,712 (1921). Kobayashi. *See* XII.

11,828 (1921). Clewlow. Method of and apparatus for disintegrating, dehydrating, and otherwise treating peat for fuel or distillation purposes. (183,566.) Aug. 10.

11,953 (1921). Ricardo. Fuel for use in internal-combustion engines. (183,577.) Aug. 10.

12,277 (1921). Tabary. *See* IX.

12,398 (1921). Gemayel. Burners for liquid combustibles. (168,853.) Aug. 10.

12,491 (1921). Key. Apparatus connected with an internal-combustion or an oil engine for converting crude oil into fuel. (183,600.) Aug. 10.

16,698 (1921). Burdon, Burdon, and Burdons, Ltd. Preheating of liquid fuel for liquid-fuel-fired furnaces. (183,673.) Aug. 10.

17,701 (1921). Adler. Process for the manufacture of decolorising-charcoal of high activity. (165,788.) Aug. 10.

17,775 (1921). Yeadon. *See* III.

18,379 (1921). Withers (Lanphier). *See* XXIII.

21,103 (1921). Florin. Gas-washers. (184,060.) Aug. 16.

27,512 (1921). Naaml. Vennoots. Metaaldraadlampenfabriek "Holland." Electric incandescent lamps and other electric apparatus in which an incandescent filament requires to be kept stretched. (183,389.) Aug. 2.

13,651–2 (1922). Igranic Electric Co., Ltd. (Cutler-Hammer Mfg. Co.). *See* XXIII.

III.—TAR AND TAR PRODUCTS.

Applications.

Erdöl- und Kohle-Verwertung A.-G., and Erlenbach. 21,048. *See* II.

Thompson (Atack). Process of manufacturing carbazol derivatives. 21,318. Aug. 4.

Thompson (Atack). Process of purifying anthraquinone or its derivatives. 21,319. Aug. 4.

Verein für Chem. u. Metallurgische Produktion. Continuously-working apparatus for distillation of tar etc. 20,364. July 25. (Czecho-Slov., 5.8.21.)

Complete Specification Accepted.

17,775 (1921). Yeadon. Stills for continuous distillation of coal tar, mineral oils, and the like. (183,682.) Aug. 10.

IV.—COLOURING MATTERS AND DYES.

Applications.

Anderson and others. 20,829. *See* VI.

Badische Anilin- und Soda-Fabrik. Process for production of a blue vat dye-stuff of the anthracene series. 21,366. Aug. 4. (Germany, 4.8.21.)

British Dyestuffs Corp., Ltd., and Hodgson. Manufacture of new intermediate compounds for production of colouring matters. 20,830. July 29.

Davies, Scottish Dyes, Ltd., Thomas, and Thomson. Production of colouring matters. 21,276. Aug. 3.

Complete Specification Accepted.

18,892 (1921). British Dyestuffs Corp., Ltd., Perkin, and Spencer. Manufacture of benzanthrone derivatives. (183,351.) Aug. 2.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Anderson and others. 20,829. *See* VI.

Bacon and Hyndman. Treatment of animal and vegetable fibres. 21,262. Aug. 3.

Barrett, Coward, and Tootal Broadhurst Lee Co., Ltd. Cellulosic material and manufacture thereof. 21,889. Aug. 11.

Billwiller. Method of manufacturing fibres etc. 21,398. Aug. 4.

Brandwood and Brandwood. Drying yarns. 21,207. Aug. 3.

Brifco, Ltd., and Macwalter. Method of rendering textile fabrics gas and water tight. 21,998. Aug. 12.

Clavel. Treatment of cellulose derivatives. 20,713. July 28.

Dehn (International Takamine Ferment Co.). Process of treating textile etc. fabrics, thread, yarn, etc. 20,206. July 24.

Dreyfus. Manufacture or treatment of artificial silk, films, etc. 20,556. July 27.

Dreyfus. Manufacture of cellulose derivatives. 20,557. July 27.

Dreyfus. Manufacture of products from cellulose derivatives. 21,915. Aug. 11.

Gruner & Reinhardt Ges. Method of production of tracing-cloth. 20,438. July 26. (Germany, 2.8.21.)

Hawkins. Drying-machines for wool etc. 20,918. July 31.

McIntosh and McIntosh. Processes for treatment of textile fibres. 20,167. July 24.

McIntosh and McIntosh. Processes for drying textile fibres. 20,262. July 25.

McIntosh and McIntosh. Treatment of textile fibres. 21,435. Aug. 5.

Moeller. Waterproofing cellulose or carbohydrates of the cellulose group. 21,049. Aug. 1. (Germany, 12.8.21.)

Moisio and Olander. Manufacture of paper. 20,299. July 25.

Nishina. Method of solidifying fibrous substances. 21,400. Aug. 4. (Japan, 1.9.21.)

Raitt. Extracting cellulose or paper-pulp from fibrous vegetable materials. 21,690. Aug. 9.

Shaw. Fabric or material, and manufacture thereof. 21,955. Aug. 12.

Ubbelohde. Process of manufacturing spinning fibres. 21,282. Aug. 3. (Germany, Feb. 16.)

Underwood, and Underwood, Ltd. Processes for treatment of fabrics, and fabrics obtained thereby. 21,936. Aug. 11.

Zust. Manufacture of cotton fabrics. 21,162. Aug. 2. (Switz., May 18.)

Complete Specifications Accepted.

3320 (1921). Sutcliffe. Preparation of vulcanised fibre. (183,497.) Aug. 10.

3377 (1921). Bloxam. (Akt.-Ges. für Anilin-Fabr.) *See* VI.

4639 (1921). Dreyfus. Manufacture of cellulose derivatives. (183,882.) Aug. 16.

6515 (1921). Trostel. Process for treating animal fibre to improve the spinning and felting properties thereof. (183,885.) Aug. 16.

8395 (1921). Carpmael (Bagley and Sewall Co.). Paper-making machines. (183,185.) Aug. 2.

11,461 and 12,115 (1921). Bloxam (Technochemia A.-G.). Manufacture of new textile products derived from animal fibres. (183,249 and 183,270.) Aug. 2.

12,190 (1921). Plausons (Parent Co.), Ltd. (Plauson). Process for the manufacture of cellulose compounds. (183,908.) Aug. 16.

14,275 (1921). Arent. Fireproofing and/or waterproofing treatment of materials. (164,730.) Aug. 2.

15,249 (1921). Classen. *See* XVII.

15,709 (1921). Smith and Co. (London, E.), Ltd., and Ellis. Process and apparatus for coating fabrics. (183,319.) Aug. 2.

17,813 (1921). British Thomson-Houston Co., Ltd. (General Electric Co.). Gas-impervious materials. (184,012.) Aug. 16.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Anderson, Baddiley, British Dyestuffs Corp., Ltd., and Hill. Process for obtaining new shades on acetyl silk and new dyestuffs for use therein. 20,829. July 29.

Brandwood and Brandwood. Apparatus for continuous dyeing etc. of textile fibres in loose state. 21,962. Aug. 12.

De Blicquy and Callebaut. Dyeing-machines. 21,963. Aug. 12.

Lomax. Treatment of yarns or threads. 21,642. Aug. 9.

McIntosh and McIntosh. Processes for bleaching etc. textile fibres. 20,263. July 25.

Society of Chem. Ind. in Basle. Method of preventing bleeding in degumming raw silk in presence of silk dyed with vat dye-stuffs. 20,229. July 24. (Germany, 13.8.21.)

Talbot. Drying and bleaching machine with sieve combined. 20,425. July 26.

White (Surpass Chemical Co., Inc.). Process of bleaching and dyeing fibre. 20,468. July 26.

Complete Specifications Accepted.

3337 (1921). Bloxam (Akt.-Ges. für Anilin-Fabr.). Process for protecting animal fibres in treating them with alkaline liquids. (183,868.) Aug. 16.

9040 (1921). Jackson and Bro., Ltd., Gass, Hammond, and Fish. Dyeing - apparatus. (183,526.) Aug. 10.

16,491 (1921). Farbw. vorm. Meister, Lucius, und Brüning. Manufacture of stable, dry, and readily-soluble vat preparations for dyeing. (171,078.) Aug. 2.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Calder, Chance and Hunt, Ltd., and Palmer. Process for condensing acid fumes evolved during concentration of sulphuric acid. 21,012. Aug. 1.

Cocksedge. Process for manufacture of a sodium compound etc. 20,492. July 27.

Codd. Production of alkali silicate solutions. 21,436. Aug. 5.

Ephraim. Method of producing sulphides and hydrosulphides of the alkali metals. 21,997. Aug. 12. (Germany, 20.8.21.)

Guggenheim Bros. Manufacture of sodium nitrate. 20,192. July 24. (U.S., Jan. 19.)

Humphries. Ammonia distillation. 20,684. July 28.

Legeler. Process for manufacture of sulphur proto-chloride. 21,401. Aug. 4. (Germany, 29.12.21.)

Scott. Manufacture of hydrogen and oxygen. 20,353. July 25.

Texas Gulf Sulphur Co., Inc. Burning sulphur. 21,261. Aug. 3. (U.S., Jan. 21.)

Complete Specifications Accepted.

10,792 (1921). Mirat and Pipereaut. Manufacture of sulphuric acid. (163,030.) Aug 2.

11,358 (1921). Plowman and Feldenheimer. Process for the grading of alkaline-earth carbonates. (183,243.) Aug. 2.

15,814 (1921). Tyrer. *See* XIII.

16,636 (1921). Wilderman. Process for the production of hypochlorites and chlorates, and apparatus therefor. (183,671.) Aug. 10.

18,333 (1921). Fairweather (Air Reduction Co., Inc.). Method of producing hydrocyanic acid. (183,348.) Aug. 2.

20,708 (1921). Priest. *See* IX.

29,835 (1921). Chem. Fabr. Griesheim-Elektron. Process and apparatus for the production of carbon disulphide from its elements. (174,040.) Aug. 2.

34,252 (1921). Deguide. Continuous process for the manufacture of caustic soda or caustic potash. (176,321.) Aug. 16.

4981 (1922). Farbenfabr. vorm. F. Bayer und Co. Process for the manufacture of hyposulphites. (176,344.) Aug. 16.

VIII.—GLASS; CERAMICS.

Application.

Jackson (Libbey-Owens Sheet Glass Co.). Means for controlling flow of molten glass. 20,573. July 27.

Complete Specifications Accepted.

11,093 (1921). Rigby. Treatment of china clay or like clays. (183,535.) Aug. 10.

11,894 (1921). Stafford. Glass and other furnaces. (183,572.) Aug. 10.

12,020 (1921). Frink. Metallic moulds for forming glass articles. (183,582.) Aug. 10.

19,812 (1921). Bailey. Tunnel ovens or kilns for firing pottery, tiles, and the like. (183,708.) Aug. 10.

20,318 (1921). Mellersh-Jackson (Libbey-Owens Sheet Glass Co.). Method of and apparatus for drawing sheet-glass. (184,053.) Aug. 16.

22,692 (1921). Atkinson, and Stein and Atkinson, Ltd. Glass furnaces. (183,373.) Aug. 2.

25,597 (1921). British Thomson-Houston Co., Ltd. (General Electric Co.). Porcelain. (184,090.) Aug. 16.

IX.—BUILDING MATERIALS.

Applications.

Abbott. Non-conducting linings etc. of heat-retaining etc. chambers. 21,450. Aug. 5.

Chandler and Wilkins. Composition for facing walls etc. 21,375. Aug. 4.

Fraser. Manufacture of artificial stone or marble. 21,337. Aug. 4.

Harris. Composition to be applied to cement work before painting. 20,333. July 25.

Jaques. Manufacture of Portland cement mortars. 20,904. July 31. (Australia, 5.12.21.)

Kleinlogel. Waterproof and dustless concrete compound. 21,290. Aug. 3. (Germany, 18.10.21.)

Kontzler. Production of hydraulic cement. 21,007. Aug. 1. (France, Feb. 20.)

Complete Specifications Accepted.

10,448 (1921). Griffiths. Roof and the like coverings. (183,530.) Aug. 10.

12,277 (1921). Tabary. Manufacture of bituminous compositions suitable for buildings and for forming road or like surfaces. (183,914.) Aug. 16.

14,275 (1921). Arent. *See* V.

15,934 (1921). Ammon. Process of treating wood. (165,784.) Aug. 2.

20,708 (1921). Priest. Vertical gas-fired kilns for burning limestone or the like. (184,057.) Aug. 16.

26,808 (1921). Frankfurter and Jansen. Process for the manufacture of coverings for floors and walls. (183,753.) Aug. 10.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Barron, Halliwell, and Hindley. Process of converting finished articles of iron etc. into stainless steel. 21,467. Aug. 5.

Barron, Halliwell, and Hindley. Method of manufacture of stainless steel. 21,468. Aug. 5.

Commin and Snook. Case-hardening of metal. 21,166. Aug. 3.

Field and Petersson. Treatment of sulphide ores and minerals. 20,623. July 27.

Hansgirg. 21,738. *See* XI.

Lysaght, and Lysaght, Ltd. Manufacture of galvanised iron. 21,362. Aug. 4.

Minerals Separation, Ltd., and Tullis. Concentration and preparation for smelting of iron ores. 21,265. Aug. 3.

Western Electric Co., Ltd. (Western Electric Co., Inc.). Treatment of magnetic materials. 20,818. July 29.

Complete Specifications Accepted.

6277 (1921). Basset. Process for the direct manufacture of iron and steel. (159,475.) Aug. 10.

6299 (1921). White (American Smelting and Refining Co.). Treatment of tin. (183,507.) Aug. 10.

8525 (1921). Maurer. Joining together of precious and other metals. (183,188.) Aug. 2.

8530 (1921). Pacz. Method of producing high temperatures and the use thereof for reducing refractory oxides. (160,427.) Aug. 10.

10,182 (1921). Herkenrath. Apparatus for atomising fusible metals. (161,194.) Aug. 2.

10,830 (1921). Trent Process Corp. Process of reducing ores. (169,950.) Aug. 2.

11,049 (1921). British Thomson-Houston Co., Ltd. (General Electric Co.). Methods of refining silicon steel and metals and alloys. (183,217.) Aug. 2.

11,065 (1921). Ferolite, Ltd., and Clapp. *See* II.

11,437 (1921). Danforth, jun. Open-hearth furnaces. (183,247.) Aug. 2.

12,205 (1921). Blei- und Silberhütte Braubach A.-G. Process for the metallurgical treatment of materials containing precious metals. (167,741.) Aug. 16.

12,244 (1921). Koppers. Process of desulphurising iron and steel. (162,618.) Aug. 10.

19,363 (1921). Waldo. Reduction of magnesium compounds. (167,164.) Aug. 10.

19,538 (1921). Nevill and Soanes. Process for the extraction of copper from its ores. (172,926.) Aug. 16.

26,684 (1921). Sahlin. Automatically-charged blast-furnaces. (184,094.) Aug. 16.

30,605 (1921). Teisen. Gas-heated crucible furnaces. (183,394.) Aug. 2.

XI.—ELECTRO-CHEMISTRY.

Applications.

Antonoff. Electric batteries. 21,536. Aug. 8.

British Thomson-Houston Co. (General Electric Co.). Electric heating-units. 20,209. July 24.

Chloride Electrical Storage Co., Ltd. (Ford). Electric storage batteries. 21,837. Aug. 10.

David and Dutt. Electric batteries. 21,520. Aug. 8.

David and Dutt. Electric primary battery. 21,635. Aug. 9.

David and Dutt. Electric cells. 21,636. Aug. 9.

Hansgirg. Electrolysis of zinkiferous materials. 21,738. Aug. 9. (Austria, 30.9.21.)

Lodge-Cottrell, Ltd., and Lodge. Safety device for electric precipitation apparatus. 21,588. Aug. 8.

Reynard. Manufacture of plates of electric storage batteries etc. 20,485. July 26.

Rickets. Electrically inducing chemical action. 21,173. Aug. 3.

Scott. Electrodes and method of manufacturing same. 20,350. 20,351. July 25.

Scott. Electrolytic cells. 20,352. July 25.

Starley, and Van Raden & Co. Electric storage cells. 21,481. Aug 5.

Tapping and Thornley. Manufacture of plates of electric storage batteries etc. 20,485. July 26.

Complete Specifications Accepted.

11,065 (1921). Ferolite, Ltd., and Clapp. *See* II.

13,661–2 (1921). **Burgess Battery Co.** Dry cell and method of manufacturing the same. (163,317–8.) Aug. 10.

16,221 (1921). Genese. Electric storage batteries or accumulators. (183,329.) Aug. 2.

30,625 (1921). Lodge Fume Co., Ltd. (Möller). Method and device for separating suspended particles from electrically-insulating fluids, especially gases. (183,768.) Aug. 10.

XII.—FATS; OILS; WAXES.

Applications.

Golding, and United Alkali Co., Ltd. Manufacture of cleaning-compositions. 20,730. July 28.

Lever Bros., Ltd., and Thomas. Hydrogenation of oils and fats. 21,585. Aug. 8.

Maxted. Distillation of fatty acids etc. 20,386. July 26.

Vijdam. Manufacture of soap. 20,484. July 26. (Holland, 1.8.21.)

Zipser. Extraction of fatty etc matters by volatile solvents. 20,622. July 27. (Austria, 10.9.21.)

Complete Specifications Accepted.

8409 (1921). Schicht A.-G., and Grün. Manufacture of synthetic waxes. (193,186.) Aug. 2.

10,831 (1921). Trent Process Corp. *See* II.

11,712 (1921). Kobayashi. Process of manufacturing liquid hydrocarbons from fish oils. (170,264.) Aug. 2.

17,116–7 (1921). Goslings. Process for the purification of oils and fats. (167,462–3.) Aug. 16.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Alexander (Stokes). Synthetic resins, and process of making same. 21,914. Aug. 11.

Dewey and Almy Chemical Co., and General Rubber Co. Sealing-compositions. 21,823. Aug. 10. (U.S., Apr. 28.)

Edbrook and Edwards. Lacquers for shoe heels etc. 20,445. July 26.

Flurscheim. Plastic compositions. 21,664. Aug. 9.

Harris. 20,333. *See* IX.

Rimmer. Paint etc. 21,307. 21,308. Aug. 4.

Roberts and Schultz. Patent leather imitation paint. 21,416. Aug. 5.

Rosenbaum. Method of rendering coats of distemper and mineral colours washable. 20,334. July 25.

Shawinigan Laboratories, Ltd. Phenolic condensation products, and manufacture thereof. 20,265. July 25. (U.S., 25.7.21.)

Weller. Waterproof distempers and water paints. 21,832. Aug. 10.

Williams. Compositions for coating and decorating plaster, wood, iron, etc. 20,305. July 25.

Complete Specifications Accepted.

5257 (1921). Bakelite-Ges., and Hessen. Manufacture of condensation products from phenols and aldehydes. (159,461.) Aug. 2.

7286 (1921). Günter. Oil and varnish colours miscible with water. (183,177.) Aug. 2.

8608 (1921). De Waele. Inks and other pigmenting and like compositions. (183,513.) Aug. 10.

13,256 (1921). Marks (Ideal Coated Paper Co.). Method of and means for coating an article with waterproof adhesive. (183,617.) Aug. 10.

13,744 (1921). Anderson and Maclaurin. Preparation of synthetic resins. (183,629.) Aug. 10.

15,814 (1921). Tyrer. Manufacture of red oxide of iron. (183,323.) Aug. 2.

Segal. Means for preservation of matter. 21,722. Aug. 9.

Segal. Means for preserving cereals etc. in storage receptacles. 21,730. Aug. 9.

Thomas. Food for infants. 20,902. July 31.

Willey. Process for preparing food. 21,949. Aug. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

11,057 (1921). Morison. *See* I.

12,791 (1921). King. Apparatus for separating iron and other magnetically permeable metals from flour, grain, and the like. (183,940.) Aug. 16.

21,039 (1921). Lamy. Apparatus for the treatment of sewage water. (167,504.) Aug. 2.

23,583 (1921). Beylik and Schwartzlose. Process of making pectin-containing material and resulting product. (184,081.) Aug. 16.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Barr, and British Oxygen Co., Ltd. Capsules or containers for compressed or liquefied gas impregnated with emanations from radio-active substances. 20,210. July 24.

Boehringer Sohn, and Wieland. Method of preparing acetylene for anæsthetising. 20,241. July 24.

British Dyestuffs Corp., Ltd., and Hodgson. Process for manufacture of dichlorfluorane. 20,831. July 29.

Distillers Co., Ltd., and Meyer. 21,940. *See* XVIII.

Farbw. vorm. Meister, Lucius, und Brüning. Manufacture of thiohydrins. 21,717. Aug. 9. (Germany, 27.8.21.)

Imray (Farbw. vorm. Meister, Lucius, u. Brüning). Manufacture of alkylated acids and derivatives thereof. 22,006. Aug. 12.

Ramage. Hydrocarbon peroxide and process of producing same. 21,734. Aug. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

8302 (1921). Barrett Co. Manufacture of formaldehyde. (163,980.) Aug. 2.

9927 (1921). Haddan (Zollinger-Jenny). Process of converting organic acids into esters. (183,897.) Aug. 16.

12,867 and 29,896 (1921). Fitzgerald. Process for preserving the fluidity of blood. (183,943.) Aug. 16.

17,710 (1921). Hoffmann-La Roche & Co., A.-G. Process for the manufacture of allyl-arsinic acid. (167,157.) Aug. 10.

19,177 (1921) and 8367 (1922). Van Ruymbeke. *See* XVIII.

23,391 (1921). Soc. Chim. Usines du Rhône. Process for the production of silver alcosols with the aid of organic bodies. (173,733.) Aug. 10.

29,872 (1921). Stockholms Superfosfat Fabriks Aktiebolag. Method of manufacturing acetone from acetic acid. (171,391.) Aug. 16.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Dewey. Kinematographic etc. screens. 20,851. July 31.

Edbrook and Edwards. Manufacture of non-inflammable films for kinematographs etc. 20,444. July 26.

Miller. Photographic films. 20,373. July 25.

COMPLETE SPECIFICATIONS ACCEPTED.

8590 (1921). Lage. Method of producing photographic plates for indirect tri-colour photography. (183,189.) Aug. 2.

13,524 (1921). Christensen. Multi-colour screens for photography. (163,311.) Aug. 2.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Du Pont de Nemours and Co. High explosives. 21,946. Aug. 11. (U.S., 11.8.21.)

Eschbach. Process for manufacture of blasting detonators. 20,249. July 24.

XXIII.—ANALYSIS.

APPLICATIONS.

Davidson. Means of regulating gas flow to gas calorimeters. 20,384. July 26.

Macdonald. Apparatus for analysis of coal gas etc. 20,991. Aug. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

18,379 (1921). Withers (Lanphier). Method of and apparatus for measuring the calorific value of gas. (184,025.) Aug. 16.

13,651–2 (1922). Igranic Electric Co., Ltd. (Cutler-Hammer Mfg. Co.). Gas-calorimeters. (183,408–9.) Aug. 2.

I.—GENERAL; PLANT; MACHINERY.

Patents.

Liquids under gaseous pressure; Devices for the withdrawal of ——. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 175,958, 21.12.21. Conv., 23.2.21.

The conduit by which a liquid is withdrawn from a high-pressure storage cylinder is provided with two separate means of choking to create the necessary loss of pressure, a pressure gauge being provided between the two devices. The first throttle may be an adjustable valve and the second a pipe coil of narrow bore and great length. —B. M. V.

Grinding mills; Method of grinding, and attachment for ——. H. F. Winslow. E.P. 182,730, 24.10.21.

In a series of rolls grinding viscous material, the coarser material has a tendency to work towards the ends of the rolls. One of the later rolls is therefore provided on the circumference, near its ends only, with a pair of scraping devices which return the material to the middle portion of an earlier pair of rolls.—B. M. V.

Mixing and/or disintegrating machines. C. E. Gardner. E.P. 182,850, 1.3.21.

An inner and outer set of helical blades rotate in opposite directions in a casing, the adjacent edges of each set of blades being serrated. The blades of the inner set run at a higher peripheral speed but have a smaller pitch than those of the outer set, and the former alone are stopped during discharge of a batch. The inner blades may be provided only near the outlet, or they may extend nearly the full length of the machine. For continuous work the outlet may be at one end of the casing and above the level of the axis, and the radial arms of the blades may be arranged to scrape the ends of the casing to diminish the pressure thereon and may be provided with wings to deflect the material to the outlet. Alternatively the outlet may be in the bottom of the casing at about the middle of its length; in this case the helical blades are of right-hand pitch on the side of the outlet and of left-hand pitch on the other side.—B. M. V.

Refrigerating apparatus; Concentration of brine and similar solutions used as the circulating medium in ——. Heenan and Froude, Ltd., and G. H. Walker. E.P. 182,982, 3.5.21 and 25.5.21.

Brine that is used as the circulating medium in refrigerators becomes gradually diluted. To rectify this it is heated (in a heat interchanger) by means of the hot high-pressure gas from the compressor of the plant and concentrated by exposing it to air in a device such as a spray cooling tower or while still flowing over the heating coils.—B. M. V.

Heating and boiling liquids; Means for ——. W. B. Briggs and S. H. Buxton. E.P. 183,039, 19.7.21.

A steam heater for placing in tanks, such as wort-coppers, is constructed of a horizontal ring pipe, with inlet and outlet for steam and condensed water at about opposite ends of a diameter; the ring may be shaped as a hexagon and may be built up of six straight pieces each with a 120° bend near one end. Upstanding from the ring pipe are a number of vertical pipes with closed upper ends, the steam being diverted into and out of the upright pipes by means of diaphragms partly obstructing the ring pipe and extending some distance up the vertical pipes.—B. M. V.

Dry kiln. N. H. and H. L. Henderson. U.S.P. 1,422,202, 11.7.22. Appl., 14.5.21.

A drying room is situated above a heating chamber and circulating chambers, the latter communicating with the bottom of the drying room and, through automatic pressure-operated dampers, with the heating chamber. Chimneys provided with dampers can draw air from the circulating chambers, and a steam injector can supply air to the heating chamber from either the external atmosphere or from the circulating chambers.—B. M. V.

Drying kiln and process. M. L. Mueller, Assr. to Northwest Blower Kiln Co. U.S.P. 1,423,136, 18.7.22. Appl., 20.7.21.

A steam engine drives a fan which circulates air through the kiln, and the exhaust steam from the engine is delivered in advance of the fan to the air currents thus circulated.—H. H.

Dehydrator or dryer. D. P. Power, Assr. to E. P. Babcock and F. Delano. U.S.P. 1,422,620, 11.7.22. Appl., 21.6.21.

Ante-chambers, arranged one at each end of the drying chamber, each communicate on one side with the exterior of the drying chamber and on the other with the outer air through ports provided with controlling gates. Fans cause heated air currents to traverse the ante-chambers and the drying chamber. Automatic devices are provided to operate the gates and to control synchronously the action of the devices for effecting the movement of the air through the drying chamber. The movement of the air is reversed at predetermined intervals.—H. H.

Dehydrator. W. O. Cardin, Assr. to J. W. Freeman. U.S.P. 1,423,188, 18.7.22. Appl., 23.11.20. Renewed 21.12.21.

A casing containing means for supporting the material to be dried is situated above and communicates with a heating chamber. The latter comprises a flue leading from the source of heat, an air intake, a number of staggered baffles, and above these a pair of plates, the lower one with relatively large holes and the upper one with relatively small holes, to distribute the heated air. —B. M. V.

Dryer. E. B. Ayres and T. H. Rhoads, Assrs. to Proctor and Schwartz, Inc. U.S.P. 1,423,298, 18.7.22. Appl., 1.7.21.

A casing is divided into three longitudinal chambers in each of which is a conveyor for the material to be dried. Heating pipes are provided in the upper part of the casing, and in the upper part of the central chamber is a row of fans which circulate the air up the central and down the two outer chambers.—B. M. V.

Drying process and apparatus. C. Field, Assr. to Chemical Machinery Corp. U.S.P. 1,423,928, 25.7.22. Appl., 21.1.19.

A heated drying medium is supplied to a conduit into which the material to be dried is sprayed. A primary collector for the dried material is disposed in the conduit, and a secondary collector, connected with the conduit, is spaced from the primary collector. Means are provided for re-circulating the drying medium through the conduit and the primary collector or alternatively directing it through the secondary collector.—H. H.

Centrifugal machine. S. H. Hall, Assr. to De Laval Separator Co. U.S.P. 1,422,852, 18.7.22. Appl., 6.8.21.

A top disc is arranged above the separating space of the bowl of a convertible centrifuge, and alternative means are provided, the one affording a free flow for heavy liquid from the peripheral part of the separating space to the space above the disc, and the other obstructing the flow to that space. —H. H.

Centrifugal machine. C. H. Hapgood, Assr. to De Laval Separator Co. U.S.P. 1,422,856, 18.7.22. Appl., 5.5.21.

A liner within the bowl of a convertible centrifuge is formed of a series of discs for dividing the liquid into layers, and openings are provided for the escape of liquid constituents of different specific gravities. A removable annular gasket when inserted in the bowl is confined in non-adjustable position between a removable bowl cover and the liner so as to block the escape of liquid through one of the openings.—H. H.

Heat exchanger or condenser. P. St. Clair, jun., Assr. to The Nitrogen Corp. U.S.P. 1,423,695, 25.7.22. Appl., 9.10.19.

A heat exchanger comprises a number of units connected in series, each unit having a spiral ribbon both inside and out and surrounded by a larger tube, so that two helical passages are formed, one for each fluid.—B. M. V

Catalysing material; Process of preparing ——. E. Weintraub, Assr. to General Electric Co. U.S.P. 1,423,978, 25.7.22. Appl., 26.3.18.

Fibrous material is impregnated with gaseous nickel-carbonyl at a pressure less than atmospheric, and the nickel-carbonyl is subsequently decomposed by heat.—L. A. C.

Filter beds; Process and apparatus for continuously washing ——. H. Jung. G.P. 348,197, 2.4.19. Addn. to 340,183.

In a process carried out in accordance with the previous patent (*cf.* E.P. 176,495; J., 1922, 399 A), the washing fluid passes through the filter plates into the washing region, and in the washing process flows in the direction of rotation of the filtering elements into the pressure chambers where it is filtered. A rotary or oscillating brush, pendulum, or strip is disposed in the washing region, in order to obtain a high velocity of the washing fluid in that region.—J. S. G. T.

Introducing solid matter at the foot of a tall column of liquid, without occasioning loss of liquid; Apparatus for ——. J. Fahrni. G.P. 349,084, 9.12.19.

Solid matter is introduced through one side into a chamber not containing liquid, disposed at the foot of the column, and is then pushed from below by a piston through the upper part of the chamber into the liquid. Normally the chamber is closed above by a sliding cover. The device may be applied to introduce material for removing boiler scale, without interrupting the working of the boilers etc.—J. S. G. T.

Retorts; Apparatus for charging and discharging ——. W. D. Scott-Moncrieff. E.P. 182,888, 18.8.21.

Centrifugal machines; Apparatus [plough] for removing accumulation of sugar or cake from the filtering walls of ——. E. Daniels, G. McKinlay, and E. Kopke. E.P. 183,028, 23.6.21.

Dehydrating plastic materials. E.P. 183,097. *See* V.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Carbonisation; Is the —— *of coking coals endothermic?* K. Sieben. Brennstoff-Chem., 1922, 3, 209—211.

Widely differing results have been obtained by various investigators as to the heat requirements of the coking process. The work of Otto, Mahler, Wilczek, Simmersbach, Euchene, and Hollings and Cobb is reviewed. Rau (unpublished communication), as the result of a critical survey of the available literature, states that the heat required for the decomposition of cellulose is 14%, for wood, 12%, for peat, 8%, for lignite, 3—7%, and for coal, 0—3% of the heat of combustion, and that the average distribution of the heat units available in the original coal is divided between the coke, tar and gas in the following proportions:—Coal with 60% coke yield: coke, 60%, gas, 27%, tar, 9%, and 4% evolved exothermically; coal with 85% coke yield: coke, 80%, gas, 16%, tar, 3%, and 1% evolved; peat: coke, 63%, gas, 19%, tar, 12%, and 6% evolved; wood: charcoal, 61%, gas, 6%, tar, 20%, and 13% evolved. The heat losses in actual practice can be set down as follows: loss due to radiation and conduction, 40 cals./kg., loss due to evaporation of moisture in the coal and superheating of the resulting steam, 100 cals./kg. (for 10% moisture), loss due to quenching coke, 270 cals./kg., loss in gases of distillation, 75 cals./kg., chimney losses, 145 cals./kg., making a total of 630 cals./kg. These results are theoretical losses, and could not be reproduced in practice. In spite of this, coke-oven firms are giving guarantees of about 600 cals./kg. for the heat losses on their ovens, and values of 630 cals./kg. have been recorded in practice. If the reactions involved in coking were endothermic, this would not be possible, but an exothermic reaction will account for the partial balance of such losses.—A. G.

Lignite coke; Ignition temperature of ——. F. Plenz. Gas- u. Wasserfach, 1922, 65, 478.

Lignite coke was placed in one arm of an iron U-tube, the other arm of which was heated and was filled with aluminium foil, which served to heat a current of air passing through the U-tube. Slow oxidation takes place at low temperatures, and this increases in amount as the temperature rises. This increase in oxidation can be measured by the percentage of carbon dioxide given off per unit of time with a constant current of air. The U-tube was heated in a metal bath which was kept in constant agitation. The carbon dioxide evolved increased from 0·6% at 204° C. to 17·4% at 248° C., and increased quite suddenly from 2·0% at 239° C. to 17·6% at 246° C. Cokes prepared at a low temperature ignited at a lower temperature than those prepared at higher temperatures.—A. G.

Tar recovery from by-product coke-oven gas; Distribution of ——. F. M. Washburn and G. E. Muns. Chem. and Met. Eng., 1922, 27, 119—120.

An investigation was made of the proportion and composition of tar condensed at different points in the circuit of a by-product recovery plant. It was found that over 90% of the tar (anhydrous) was condensed in the suction main and primary coolers, 2% in the exhausters, and only 7% in the tar extractors. The successive condensates show a fall in sp. gr. and increase in the content of more volatile constituents, corresponding to the fall in temperature along the circuit.—C. I.

Benzene; Recovery of —— from illuminating gas by means of active carbon. A. Engelhardt. Gas- u. Wasserfach, 1922, **65**, 473—477.

The carbon used for the absorption of benzene from gas should take up at least 25% of its weight of benzene from air containing 25 g. per cub. m. at 20° C. The crude gas is passed into a main leading to two filter-boxes containing the active carbon and arranged in parallel, so that whilst one is being used for the remoal of benzene, the other may be subjected to a current of superheated steam which vaporises the benzene, the steam and benzene vapour being passed through a condenser, from which the benzene is withdrawn on separation. The first box is connected at its outlet with a gas cooler, in which the residual steam is condensed, and the water withdrawn through a siphon. The boxes have a capacity of 10 cub. m. and contain about 195 kg. of active carbon. Each filter will yield, on treatment with steam, about 35 kg. of benzene. By arranging the boxes in series, the first box can be made to yield up to 50 kg. per charge, and the heavier hydrocarbons then also condense in the first box, and this leads to increased absorption of benzene. The carbon should not break down on steaming and should not be brittle, otherwise clogging of the boxes is liable to occur. The average figure obtained was an absorption of 37 g. of crude benzol per cub. m. of gas, the smallest weight being 30 g. and the highest being 42 g. The crude benzol recovered had sp. gr. 0·885 at 15° C., as against a product of sp. gr. 0·900—0·930 at the same temperature, obtained with the use of scrubbing oil. It contained only about 2% of constituents boiling above 140° C., whilst with oil-scrubbing of the same gas, the product contained 29% boiling above 180° C. A thermal balance is given for the process.—A. G.

Montan wax; The acids of ——. H. Tropsch and A. Kreutzer. Brennstoff-Chem., 1922, **3**, 177—180, 193—198, 212—215.

When lignite is treated with benzene or benzene-alcohol mixtures, crude humic acids are extracted, from which three acids were isolated. The crude acid was esterified with methyl alcohol, and the ester distilled at 5 mm. pressure. An acid $C_{27}H_{54}O_2$, was isolated from the fraction boiling at 265°—267·5° C. This acid, named carboceric acid, has m.p. 82° C., and is probably identical with an acid extracted from Chinese wax by Gascard (*cf.* J., 1920, 495 a). It crystallises from alcohol in dendritic needles. Montanic acid was prepared and the formula, $C_{29}H_{58}O_2$, was confirmed. Another acid, of formula, $C_{25}H_{50}O_2$, occurred in small amounts. (*Cf.* J.C.S., Sept.)—A. G.

Montan wax; The colouring constituents of ——. J. Marcusson and H. Smelkus. Chem.-Zeit., 1922, **46**, 701—702.

The portion of montan wax soluble in ether contains a waxy substance of low melting-point and a dark brown resin which yields insoluble compounds with nitric acid and sulphuric acid. It has an acid value of 16, iodine value 51, and saponification value 68. The ether-insoluble portion of the original wax contains a brownish-black unsaponifiable substance, soluble in benzene, and a mixture of esters of hydroxy acids. The acids themselves form a dark-coloured, friable powder which yields about 70% of saturated fatty acids on reduction. It contains 3·1% of sulphur and is soluble in benzene, chloroform, and amyl alcohol, but not in alcohol, ether, or acetic anhydride. (*Cf.* J.C.S., Sept.)
—A. R. P.

Viscosimeters; Fuel oil ——. W. H. Herschel. Chem. and Met. Eng., 1922, **26**, 1175.

The Saybolt "Furol" viscosimeter has been designed for the testing of bunker fuel oils, for which purpose the Saybolt "Universal" instrument is unsuited. The dimensions are similar to those of the "Universal" instrument, except for the internal and external diameters of the outlet tube. The relationship between c.g.s. units and "Furol" time in seconds is, kinematic viscosity $= 0{\cdot}022t - 2{\cdot}03/t$, whilst the corresponding relationship for the Redwood No. 2 (Admiralty) viscosimeter is, kinematic viscosity $= 0{\cdot}0293t - 0{\cdot}403/t$. Tables giving conversion factors for the Universal, Furol, and Admiralty (Redwood) instruments are given.
—H. M.

Effluent liquors from distillation of ammoniacal liquor. See XIXb.

Patents.

Peat and similar material; Process and apparatus for pressing ——. K. Maus. E.P. 182,503, 1.2.21.

Wet peat is slowly subjected to pressure within a chamber the walls of which are provided with wire netting or other metallic filtering medium. Movable transverse partitions, also provided with a permeable covering, are arranged within the chamber. The pressing faces of the piston, the partitions, and the bottom of the chamber are so shaped that the resulting pressed blocks are thinner in the middle than at the edges.—H. Hg.

Peat; Plant for the continuous decomposition and dehydration of ——. E. Laaser and C. Birk. G.P. 348,472, 21.5.20.

The raw peat is fed into one arm of a V-shaped tube, in which it is preheated by waste heat, and is continuously forced forward and upward into the other arm of the apparatus, where it is heated in a special heater; the water which separates drains through the mass and is withdrawn at the lowest part of the tube. The resulting pulp is fed through a valve into a dryer operated at reduced pressure, the vapour evolved being compressed and utilised for heating the dryer.—A. G.

Artificial fuel; Process and apparatus for the production of ——. R. Bowen. E.P. 182,578, 8.4.21.

A mixture for producing a laminated fuel such as is described in E.P. 109,995 (J., 1917, 1173) is delivered from a hopper on to an inclined oscillating plate and thence into a mould. The bottom plate of the mould is oscillated vertically by means of adjustable rotating cams. After the mould is filled, continuous pressure is applied from the top by means of a weighted plunger or other device, while the material is consolidated by the oscillations of the bottom plate. Vertical knives, capable of being oscillated by the bottom plate, may be placed in the mould whilst it is being filled.
—H. Hg.

Fuel; Means for continuous predrying of ——. O. Nordström and A. Mörck. U.S.P. 1,423,728, 25.7.22. Appl., 10.11.20.

A tower-shaped trellis work is arranged centrally within a vertical tower with perforated walls, which is surrrounded by a gas-tight casing. The fuel is fed in at the top of the tower, and hot gases are introduced at the base of the trellis work. The conical base of the tower rotates, and is provided with ribs arranged spirally, to facilitate the continuous discharge of the dried fuel.
—A. G.

Burners for burning metaldehyde. Elektrizitätswerk Lonza, and A. Busch. E.P. 182,582, 11.4.21. Addn. to 181,512 (J., 1922, 607 a).

A retainer is provided for the block of metaldehyde and is adjustable relative to the outer sheath. A perforated cup-shaped carrier for supplementary supplies of metaldehyde is attached to the sheath and is thermally insulated therefrom.—H. Hg.

Coking retort ovens. Coking retort oven heating flues. E. H. Warden. E.P. (A) 182,697, 19.7.21, and (B) 182,702, 26.7.21.

(A) IN connexion with coke ovens having two series of vertical triangular heating flues between each pair of ovens (*cf.* E.P. 155,316; J., 1921, 112 A; 1919, 710 A), a separately controlled gas supply is provided either for each series of flues or for the two series of flues which are nearest each oven, in order that the temperature of each oven may be independently regulated. (B) The interior partitions forming the triangular flues are disposed alternately normal to both walls and as diagonals, which may or may not be parallel to one another, of the spaces formed by the normal partitions. Parts of the diagonal partitions are integral with bricks forming part of a normal partition, and all the bricks are laid so that they break joint in adjacent courses.—H. Hg.

Coke; Process and apparatus for cooling —— with inert gases on the counter-current principle, with simultaneous recovery of the sensible heat. Zeche de Wendel, and H. Schwenke. G.P. 348,654, 29.3.19.

THE separate charges of a battery of coke ovens are introduced into separate cooling units, so that the new hot charge is placed at the end of the cooling installation, where the cooling medium leaves the plant, whilst the cooling gas is introduced where the coke is withdrawn. The cooling chambers are so connected that while gas is being drawn through some of them, one is being filled with a fresh charge and another is being emptied.—A. G.

Water-gas plant; Enriched ——. R. Maclaurin. E.P. 182,648, 1.6.21.

A GENERATOR and combustion chamber are placed alongside of each other and are so operated that during the blow the primary air always enters the generator below the level of the fresh coal, and passes downwards before entering the combustion chamber. During the run, the steam, or mixture of steam and oil, enters at the top of the combustion chamber and passes down through highly heated material before entering the ash zone of the generator chamber. The resulting gases leave through the fresh fuel at the top, and the distillation gases thus produced mix with the water-gas.—A. G.

Coking chamber for [gas] generators. P. Jaworski. U.S.P. 1,422,206, 11.7.22. Appl., 26.8.21.

A CASING is provided with an internal feed hopper and is supported some distance above a bottom plate so as to leave an unrestricted annular space serving as an inlet for the generator gases and outlet for the coke.—B. M. V.

Gas and ammonia yield in carbonisation of coal; Process for increasing the —— with the introduction of protecting gases in the carbonisation chamber. Bunzlauer Werke Lengersdorff u. Co. G.P. 349,908, 23.4.19.

THE protective gases to be passed through the charge, *e.g.*, coal gas, carbon monoxide, water-gas, or the like, are first moistened by passing them through a bath of boiling water, the supply of heat to which is carefully controlled. Dry gas may be also used in conjunction with steam. The ammonia yield increased from 2·08% (calculated as sulphate) with dry gas to 3·08% with moistened gases. Cracking of the tar is also reduced.—A. G.

Gas; Production of a —— of high calorific value, similar to water-gas, with recovery of tarry by-products. Dellwik-Fleischer Wassergas Ges. m. b. H. G.P. 350,443, 14.2.20.

THE products of the blow are taken off through a central pipe extending halfway down the shaft of the producer, whilst the products of the run are separately withdrawn through a port, high up in the side of the producer. It is claimed that the presence of cores of raw fuel in the lower part of the producer is thus avoided, and the tar yield is increased.—A. G.

Gas; Apparatus for and process of purifying ——. A. L. Stevens. U.S.P. 1,423,696, 25.7.22. Appl., 22.9.19.

A RESERVOIR containing a purifying liquid is provided with a by-pass between the top and bottom and with a grate supporting a packing material which provides voids for subdividing the gas into minute currents. The gas is supplied by a conduit below the grate and taken away by another conduit above the cleansing zone.—B. M. V.

Montan wax; Production of solid colloids from crude ——. E. Last, and H. T. Böhme A.-G. G.P. 350,622, 23.10.17.

CRUDE montan wax is treated at high temperature, and if necessary, under pressure, with a small quantity of concentrated caustic alkali solution until the product is completely miscible with liquid hydrocarbons to form a colloidal solution. In place of caustic alkalis, alkaline-earth hydroxides may be used or compounds of the type of sodium aluminate. In contrast to the original material, the product is miscible with water to give a homogeneous emulsion or colloidal solution, which can be precipitated by acids, salts of heavy metals, and acid salts. By using only a small quantity of water, a stiff paste is obtained, which can be diluted with water. With solutions of the crude wax in hydrocarbons viscous oils to semi-solid pastes are obtained by the process.—A. G.

Montan wax; Production of solid colloids from crude ——. H. T. Böhme A.-G., Chem. Fabr., and E. Last. G.P. 352,506, 17.4.18. Addn. to 350,622.

SOLID alkalis are used in the process described in G.P. 350,622 (*cf. supra*), avoiding excess over what is required for combination.—A. G.

Montan wax; Production of —— from lignite. A. Riebeck'sche Montanwerke A.-G. G.P. 352,902, 15.5.19. Addn. to 325,165 (J. 1920, 814 A).

TOLUENE is used instead of benzene in the process described (*loc. cit.*)—A. G.

Lubricating oils; Production of —— of low setting point. Galizische Naphtha A.-G. "Galicia," and H. Burstin. G.P. 352,010, 15.7.19.

THE fraction obtained between the lamp oil and lubricating oil fractions in the distillation of crude petroleum is passed through a tube heated to redness. The vapours are condensed and the light fraction removed by distillation, the amount removed varying according to the character of the lubricating oil desired.—A. G.

Lubricants; Production of —— of high viscosity or consistency. E. Last, and H. T. Böhme A.-G. G.P. 352,727, 25.10.17.

ONE of the solid colloidal products described in G.P. 350,622 (*cf. supra*) is dissolved in ordinary lubricating oils, preferably at high temperatures. An addition of 0·5% of colloid to a mineral oil of sp. gr. 0·9 increases the viscosity at 50° C. to twice the figure for the oil alone, and addition of 1%

gives a figure 4 times that of the original viscosity, whilst 2% of added colloid gives a viscosity 10 times as great as that of the lubricating oil alone. By the addition of still greater quantities of colloid, lubricants of high viscosity can be produced. —A. G.

Paraffin; Process for the direct production of —— from bituminous earths. W. Scheffer and S. Herzberg. G.P. 352,919, 20.11.17.

The earth is placed at the head of a slightly inclined bench, and is then strongly heated, so that the paraffin is liquated from the earth and runs down the hot inclined plane, at the foot of which it is collected. The paraffin obtained is almost white in colour and is free from earthy matter.—A. G.

Petroleum-like products; Production of ——. F. Leibbrandt. G.P. 353,286, 10.5.19.

Acetone and dihalogen compounds of ethylene are heated at high temperatures with zinc dust in a closed vessel. Aluminium or magnesium may be used instead of zinc. For example, acetone, ethylene dibromide, and zinc dust may be heated for 3 hrs. in a closed vessel to 150° C. The clear yellow, strongly fluorescent product of the reaction is filtered from excess zinc dust, shaken with dilute caustic soda solution, so that zinc bromide goes into solution, and the oily portion is separated and dried. The final product, free from halogen and oxygen, is very similar to the higher boiling fractions of Russian petroleum. Small quantities of terpenes are produced as by-products. The refined products can be used for the same technical purposes as the higher boiling fractions of mineral oil, *e.g.*, as lubricating oils.—A. G.

Gas; Process for making ——. J. U. McDonald. E.P. 159,886, 8.3.21. Conv., 10.3.20.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Carbonising furnaces or retorts. L. H. Bonnard. E.P. 182,542, 31.3.21.

The retort consists of a horizontal stationary cylinder, along the axis of which revolves a shaft, bearing spiders at right angles to its length, the spiders being attached to scrapers parallel with the sides of the retort and almost touching the inside of the chamber. The gases of combustion from a furnace are caused to pass spirally round the exterior of the retort, and the products of distillation or carbonisation are withdrawn midway along the retort through an orifice in the crown of the cylinder. Arrangements are made for the temperature at the outlet end to be limited to any desired temperature by the disposition of the burners. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 9550 of 1886, 19,310 of 1896, 106,084 and 106,636; J., 1897, 750; 1917, 863; 1918, 84 A.)—A. G.

Distillation of carbonaceous materials; Apparatus for the ——. P. M. Salerni. E.P. 182,601, 25.4.21.

The material is distilled at a low or moderate temperature in a stationary horizontal cylinder, which is externally fired, and within which is a rotating horizontal shaft. The shaft bears spiders or arms, which carry scrapers at their extremity, the scrapers being arranged so as to agitate the the mass without propelling it through the retort. The depth of the charge in the retort is regulated by means of a baffle-plate placed at or near the end of the retort. The products of carbonisation are withdrawn through a number of openings in the crown of the retort.—A. G.

Distilling coal; Method of and means for ——. A. W. Helmholtz, Assr. to Continuous Process Coke Co. U.S.P. 1,422,706, 11.7.22. Appl., 18.9.19.

A charge of coal is heated, with evolution of by-products, until it becomes plastic, then oil is added to control the content of volatile matter and the mass heated to a higher temperature and finally compressed to form a firm coke.—B. M. V.

Incandescence mantle bodies; Process for making strong, impregnated ——. R. and E. Süssmann. G.P. 352,652, 10.11.16.

In order to prevent the "running" of the salts used for strengthening the fabric, the mantles are exposed to ammoniacal vapours without subsequent washing. The excess ammonia can be transferred to untreated mantles, or to mantles not yet saturated with ammonia.—A. G.

Arc lamp; Inclosed —— and method of starting the same. E. Friederich, Assr. to General Electric Co. U.S.P. 1,422,553, 11.7.22. Appl., 28.1.16. Renewed 7.12.21.

Refractory metal electrodes which remain substantially intact when supporting an arc discharge are arranged within a sealed envelope, and colour is imparted to the arc by the vaporisation of a halogen salt.—J. S. G. T.

Distillation; Low-temperature ——. A. C. Michie and E. G. Weeks, Assrs. to C. H. Merz and W. McLellan. U.S.P. 1,423,134, 18.7.22. Appl., 12.11.19.

See E.P. 136,868 of 1918; J., 1920, 150 A.

Tungsten alloy filaments. E.P. 182,699. *See* X.

III.—TAR AND TAR PRODUCTS.

Cresols; Separation of m- and p- —— from coal tar crude carbolic acid. A. F. Campbell. J. Ind. Eng. Chem., 922, 14, 732—737.

By the fractional distillation of crude cresylic acid, a fraction consisting of approximately 60% of *m*-cresol and 40% of *p*-cresol can be obtained. The isomers may be separated by partial sulphonation at 40° C., at which temperature the *m*-compound is sulphonated three times as quickly as the *p*-compound. 37·5 g. of 96% sulphuric acid is added to 100 g. of the mixed cresols and warmed at 40° C. for 6 hrs. The product is poured into water, the non-sulphonated cresols extracted with benzene, the sulphonic acid (containing 80% of the *m*-compound) converted into its ammonium salt and the latter fractionally crystallised (the solubility of the *p*-salt is 19·17 and that of the *m*-salt 10·84 g. per 100 g. of water at 20° C.). The crystalline salt is decomposed with half its weight of sulphuric acid and the *m*-cresolsulphonic acid decomposed by steam, yielding 98—100% *m*-cresol. The residue from the first sulphonation is re-sulphonated with its own weight of 96% sulphuric acid, yielding in the sulphonated portion a mixture similar to the original one, and in the residue an 80% *p*-cresol from which hydrocarbons are removed and the *p*-cresol frozen out *in vacuo*.—C. I.

Cresols; Formation of addition products between —— on the one hand and ether, alcohol, acetone, benzene, etc. on the other. C. and W. von Rechenberg. Z. angew. Chem., 1922, 35, 397—398.

As mixtures of cresols with ether, alcohol, acetone, benzene, etc. give viscosity curves which are perfectly smooth and show no maximum, and the vapour pressure curves likewise show no minimum, the authors conclude that, contrary to the opinion of Berl and Schwebel (J., 1922, 399 A), no molecular addition compounds can be formed between these substances.—G. F. M.

Cresols; Formation of addition products of —— with ether, alcohol, acetone, benzene, etc. E. Berl and W. Schwebel. Z. angew. Chem., 1922, 35, 398. (*Cf. supra.*)

THE authors maintain their view that molecular compounds are actually formed between cresols and alcohol, ether, etc. In the first place the vapour pressure of the more volatile substance in the mixtures is notably less than theoretically required, and, if dissociation occurs at all, a vapour pressure minimum is not necessarily to be expected when molecular compounds are formed. Further, in regard to viscosity, the formation of molecular compounds does not necessarily cause a maximum in the viscosity curve, as the viscosity of the compound may be less than that of its components, and lastly the substitution of anisole for cresols in the above mixtures, removed the abnormality in behaviour of the latter.—G, F. M.

1.6-*Dimethylnaphthalene; Hydrogenation of* ——. F. Mayer and T. Schulte. Ber., 1922, 55, 2164—2167.

1.6-DIMETHYLNAPHTHALENE is reduced by sodium and boiling amyl alcohol to Δ^{67}-5.8-dihydro-1.6-dimethylnaphthalene, b.p. 118° C. at 10 mm., sp. gr. 0·9700 at 16° C. If the dihydro compound is reduced with hydrogen in aqueous alcoholic solution in the presence of palladium, 5.6.7.8.-tetrahydro-1.6-dimethylnaphthalene, a colourless liquid, b.p. 110°—111° C. at 10 mm., sp. gr. 0·9487 at 16° C., is obtained, which is stable towards bromine and is oxidised by nitric acid to benzene-1.2.3-tricarboxylic acid. On the other hand, if 1.6-dimethylnaphthalene is reduced at 240° C. and 20—25 atm. pressure in the presence of a nickel catalyst it gives a mixture of 1.2.3.4-tetrahydro-1.6-dimethylnaphthalene and 5.6.7.8-tetrahydro-1.6-dimethylnaphthalene, which is oxidised by nitric acid to a mixture of benzene-1.2.3- and 1.2.4-tricarboxylic acids.—H. W.

1.5-*Dihydroxynaphthalenedicarboxylic acid.* F. Hemmelmayr. Monatsh., 1922, 43, 61—65.

THE dicarboxylic acid which is formed when 1.5-dihydroxynaphthalene is heated with potassium bicarbonate under pressure is probably the 2.6-dicarboxylic acid, since it gives a dinitro-derivative from which the carboxyl-groups are easily displaced by reagents. (Cf. J.C.S., September.)—C. K. I.

Calcium sulphate; Solubility of ——in presence of calcium benzenesulphonate. E. Mameli. Giorn. Chim. Ind. Appl., 1922, 4, 293—296.

WHEN milk of lime or chalk or marble is used as a means of separating sulphonated products from the sulphonating mixture the products are sometimes contaminated with calcium sulphate to a greater extent than would be expected. Experiments showed that in presence of increasing quantities of calcium or sodium benzenesulphonate the solubility of calcium sulphate in water increases up to a certain point, beyond which no further change is produced. Thus, in this direction, calcium benzenesulphonate behaves in the same way as salts having no ion in common with calcium sulphate. This behaviour may be explained by assuming that calcium benzenesulphonate undergoes dissociation into intermediate ions, such as $C_6H_5SO_3Ca^+$ and $C_6H_5SO_3^-$, both different from those of the sulphate. The solubility of pure calcium benzenesulphonate in water in g. per 100 c.c. of solution is 1·766 at 0°, 2·001 at 10°, 1·968 at 15°, 1·844 at 20°, 1·211 at 30°, and 0·410 at 40° C.—T. H. P.

PATENTS.

Coal tar; Method of and apparatus for separating water from ——. Bismarckhütte. E.P. 163,011, 6.5.21. Conv., 6.5.20.

A VERTICAL cylinder of greater length than diameter is provided with a conical bottom having an outlet valve at its apex, and contains in the lower portion a cylindrical tar container spaced from the outer vessel and provided with conical ends. The apex of the bottom cone opens directly into the outer vessel, and the apex of the top cone is connected with a short, upright open tube. The tar in the container is heated by a heating coil, and is forced thereby through the tube at the top and projected against a plate, inclined slightly to the horizontal, at the top of the outer vessel. Water present in the tar creeps up the plate, flows over the higher edge, which is spaced from the wall of the outer vessel, and drains out of the apparatus, while the tar flows down the walls of the vessel and returns to the container through the opening at the bottom. After heating tar in the apparatus for 20—24 hrs. at 50°—65° C., the water content is reduced to about 3—4%.—L. A. C.

Naphthalene; Process for the purification of ——. The Barrett Co., Assees. of D. F. Gould. E.P. 172,937, 15.11.21. Conv., 15.12.20.

CRUDE naphthalene is agitated at about 85° C. with water or other immiscible liquid until an intimate mixture is obtained, and the mixture is then agitated slowly, with gradual cooling, *e.g.*, by the addition of cold water or other means, to about 65° C., whereupon the water and oily impurities are removed by filtration.—L. A. C.

[*Aromatic*] *hydrocarbons; Oxidation of* ——. F. W. Atack. E.P. 182,843, 9.2.21.

CATALYSTS consisting of or containing titanium compounds, *e.g.*, the oxide, are used in the oxidation of aromatic compounds, *e.g.*, of naphthalene to phthalic acid, and of anthracene to anthraquinone. A mixture of the hydrocarbon vapour and a large excess of oxygen, or gases containing it, is passed over the catalyst at 400°—500° C. The addition of, *e.g.*, 2% of oxides of nitrogen, to the gases promotes oxidation, while the addition of up to 20% of steam diminishes charring and facilitates the regulation of the supply of the hydrocarbon.—L. A. C.

Phthalimide; Manufacture of ——. British Dyestuffs Corp., Ltd., A. G. and S. J. Green. E.P. 183,044, 29.7.21.

α-Nitronaphthalene is directly oxidised by air or oxygen in the presence of a suitable catalyst, such as pumice impregnated with an oxide of vanadium or molybdenum, and heated to 300°—400° C., the main product of the oxidation being phthalimide in a yield upwards of 50% of that theoretically possible. The operation may be conducted by passing hot air over nitronaphthalene heated at 120°—130° C., and thence through an iron tube containing the catalyst. Phthalimide is condensed in small colourless needles in a large well-cooled receiver, and a small quantity of phthalic anhydride which is also formed, being more volatile, may be collected in a second receiver.—G. F. M.

Sulphonating carbon compounds; Process for ——. A. R. Grob and C. C. Adams, Assrs. to E. I. du Pont de Nemours and Co. U.S.P. 1,422,564, 11.7.22. Appl., 30.6.20.

Organic compounds are sulphonated by treatment with sulphur trioxide in a medium of liquid sulphur dioxide.—L. A. C.

9.10-*Dihalogenanthracene-β-monosulphonic acid; Manufacture of* ——. K. Schirmacher, Assr. to H. A. Metz. U.S.P. 1,422,889, 18.7.22. Appl., 23.10.20.

9.10-Dihalogenanthracene-β-monosulphonic acids are prepared by treating a 9.10-dihalogenanthracene with fuming sulphuric acid in the presence of an indifferent agent.—L. A. C.

Thionaphthene; Production of —— from coal-tar. Ges. f. Teerverwertung m.b.H. G.P. 350,737, 8.7.19.

Naphthalene obtained from coal-tar is treated with sodamide, with sodium in the presence of ammonia, or with sodium alone, and the sodium compound of thionaphthene formed thereby is separated from naphthalene and hydrolysed by treatment with water.—L. A. C.

sym.-Octohydroanthracene; Preparation of ——. *Preparation of sym.-octohydrophenanthrene.* G. Schroeter, and Tetralin G.m.b.H. G.P. (A) 352,721, (B) 352,719, 5.9.20.

(A) Pure anthracene in the form of colourless crystals of m.p. 214 C., prepared by twice recrystallising commercial anthracene from solvents, such as tetra- or decahydronaphthalene, cyclohexanol, or isopropyl alcohol, which have been treated to remove catalyst poisons, and subsequently washing the crystals with alcohol, is treated, either molten or in solution, with hydrogen in the presence of a catalyst. For example, a solution of pure anthracene in tetrahydronaphthalene is treated with hydrogen, with agitation, at 180°—200° C. under a pressure of 10—15 atm., in the presence of a small quantity of reduced nickel precipitated on fuller's earth, until 4 mols. of hydrogen has been absorbed. After separation of the catalyst, *sym.*-octohydroanthracene, m.p. 72°—73° C., b.p. 160°—162° C. at 11 mm., is separated from the solvent by distillation under reduced pressure. (B) Commercial phenanthrene is purified by agitation for 1—2 hrs. at 180°—190° C. with finely divided or low-melting metals or metal compounds, such as sodium, potassium, copper filings, pyrophoric iron or nickel (prepared by reducing the corresponding oxides in a current of hydrogen), sodamide, or calcium carbide, with subsequent distillation *in vacuo*. It is then converted into sym.-octohydrophenanthrene by treatment with hydrogen in the presence of reduced nickel as catalyst at 180°—220° C. under a pressure of 15—20 atm. until 4 mols. has been absorbed. The product is purified by sulphonation, recrystallisation of salts of the sulphonic acid produced, and subsequent decomposition of the sulphonic acid by heating with dilute hydrochloric acid. sym.-Octohydrophenanthrene, m.p. 16·7° C., b.p. 167·5° C. at 13 mm., and sp. gr. at 20° C. 1·026, can be used for the preparation of morphine alkaloids and similar compounds.—L. A. C.

Tars or oils; Process and apparatus for the distillation of ——. E. Blumner. E.P. 182,868, 29.3.21.

See G.P. 340,991 of 1920; J., 1922, 407 A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 8336 of 1909, 116, 304, and 141,223.)

Catalysts for hydrogenation: G.P. 352,439. *See* XX.

IV.—COLOURING MATTERS AND DYES.

Coupling reactions; Mechanism of ——. *II.* 1.8-*Naphthosultam and its N-methyl derivative as azo components.* W. König and K. Köhler. Ber., 1922, 55, 2139—2149.

The power of aromatic acylamines to couple with reactive diazo compounds with the formation of normal azo compounds has been attributed to their ability to react in the enolic form, Ar.N:C(OH)R and Ar.N:SR(:O).OH (*cf.* J., 1921, 428 A). This hypothesis is now abandoned since the methyl ether of 1.8-naphthosultam,  $C_{10}H_6\left\langle\begin{matrix}SO_2\\ |\\ N(CH_3)\end{matrix}\right.$ couples with diazo compounds in much the same manner as 1.8-naphthosultam. (*Cf.* J.C.S., Sept.)—H. W.

1.8-*Naphthosultam-4-sulphonic acid and certain of its derivatives.* W. König and J. Keil. Ber., 1922, 55, 2149—2155.

1.8-Naphthosultam-4-sulphonic acid, prepared by the action of phosphoryl chloride on potassium α-naphthylamine-4.8-disulphonate at 145° C. or from sulphuric acid monohydrate and naphthosultam alone or in the presence of glacial acetic acid, is much less reactive towards diazo compounds than the unsubstituted naphthosultam or α-naphthol-4-sulphonic acid. The tendency towards the formation of *o*-sulphamino dyes is considerably less than towards the formation of the analogous *p*-derivatives and very much less than towards the production of *o*-hydroxyazo dyes. (*Cf.* J.C.S., Sept.) —H. W.

Pyrazoleanthrone Yellow; Constitution of ——. F. Mayer and R. Heil. Ber., 1922, 55, 2155—2164.

Analyses of Pyrazoleanthrone Yellow (G.P. 255,641; J., 1913, 356), which is obtained conveniently in an ash-free condition by the hydrolysis of its dibenzoyl derivative with sulphuric acid, agree with the formula, $C_{28}H_{12}O_2N_4$ or $C_{28}H_{14}O_2N_4$, according to which two molecules of pyrazoleanthrone are united with loss of four or two atoms of hydrogen. The formation of a potassium salt, of mono- and dibenzyl (or substituted benzyl) derivatives and of a dibenzoyl compound proves that the replaceable hydrogen atoms of pyrazoleanthrone are retained in the new dye. The latter is extraordinarily resistant towards oxidation and only yields anthracene when distilled with zinc dust. Substituted pyrazoleanthrones can be converted into derivatives of Pyrazoleanthrone Yellow if substituents are present in positions 2 or 4, but when the substituent is present in position 8 either a dye is not produced or the substituent is removed during the process. The tinctorial properties of the dye indicate that it is allied to Flavanthrene. (*Cf.* J.C.S., Sept.) —H. W.

[Anthraquinone series;] Double decomposition [in the ——] catalysed by copper. E. Kopetschni and H. Wiesler. Monatsh., 1922, **43**, 89—92.

When 1-chloro-2-aminoanthraquinone is boiled with an excess of dimethylaniline with the addition of a small amount of copper powder or cupric acetate, a good yield of 2-aminoanthraquinone is produced, but, if potassium carbonate be added in addition to the copper powder or cupric acetate, or, if the dimethylaniline be replaced by monomethylaniline, 2-aminoanthraquinone is not obtained, although indanthrene and flavanthrene can be recognised amongst the products. (*Cf.* J.C.S., Sept.) —C. K. I.

Thiazole derivatives of the anthraquinone series; New mode of formation of ——. E. Kopetschni and H. Wiesler. Monatsh., 1922, **43**, 81—87.

Both 2-amino-1-mercaptoanthraquinone and 2.2′-diaminodianthraquinone-1.1′-disulphide, on heating with aqueous or alcoholic ammonia, give 2-aminoanthraquino-1-thiazole, which does not give a vat with hydrosulphite. Anthraquino-1-thiazole and 3-chloro-2-aminoanthraquino-1-thiazole were prepared in a similar way.—C. K. I.

Thiazoles. 2-p-Tolylbenzothiazole, dehydrothio-p-toluidine, and some related compounds. M. T. Bogert and M. Meyer. J. Amer. Chem. Soc., 1922, **44**, 1568—1572.

2-*p*-Tolylbenzothiazole, 
$C_6H_4{<}^{S}_{N}{>}C{\cdot}C_6H_4(CH_3)$

m.p. 85° C., is obtained by fusing *p*-tolanilide with sulphur or (preferably) by the oxidation of thio-*p*-tolanilide in alkaline solution with potassium ferricyanide. In contrast to the phenyl derivative, it is practically odourless when dry. The corresponding nitro and amino compounds are described, as well as various azo dyes from the latter. Dehydrothio-*p*-toluidine readily yields a benzylidene derivative, m.p. 193° C. (corr.); it is converted by Skraup's reaction into 6-methylbenzothiazolyl-2.6-quinoline, m.p. 147° C. (corr.). Diazotised Primuline couples on the fibre with benzoyleneurea (2.4-dihydroxyquinazoline), giving on unmordanted cotton yellowish-brown shades of good fastness to acids, alkalis, or bleach, but quite fugitive in daylight. (*Cf.* J.C.S., Sept.)—H. W.

Patents.

Azo dyestuffs; Manufacture of new copper compounds of substantive ——. Farbenfabr. vorm. F. Bayer und Co. E.P. 165,083, 13.5.21. Conv., 14.6.20.

The dyestuffs described in E.P. 144,310 (J., 1921, 688 A) formed by combining 1 mol. of 5.5′-dihydroxy-2.2′-dinaphthylamine-7.7′-disulphonic acid with 1 or 2 mols. of *o*-aminobenzoic acid or its derivatives, such as 4-chloro-2-aminobenzoic acid, are treated with compounds of copper, whereby new substantive dyestuffs having a greater affinity for cotton, and giving clearer shades, of excellent fastness to light and ironing are obtained. For example, 757 pts. of the dyestuff obtained from 2 mols. of 2-aminobenzoic acid and 1 mol. of 5.5′-dihydroxy-2.2′-dinaphthylamine-7.7′-disulphonic acid is dissolved in hot water and treated with a hot solution containing 499·4 pts. of copper sulphate, and after neutralising with sodium carbonate, the copper lake formed is separated and dried. It yields red-violet shades on cotton.—A. J. H.

Disazo dyestuffs; Manufacture of secondary ——. Kalle und Co., A.-G. G.P. 352,354, 12.6.14.

Compounds prepared by the action of aromatic hydrazines and sulphites on *p*-aminoazo- or *p*-hydroxyazo compounds are treated with alkalis and then with oxidising agents, whereby the hydrazo groups are oxidised, yielding dyestuffs containing at least 2 azo groups, $R.N_2.Ar.NH.NH.R' \rightarrow R.N_2.Ar.N_2.R'$ (R and R′ = the residue of a diazo compound and an aromatic hydrazine respectively, and Ar = an aryl group). Oxidation, by treatment with the calculated quantity of a persulphate or hypochlorite, can be effected on the fibre, oxidation being finished when spotting with acids has no effect on the shade. —L. A. C.

Cotton dyes. H. Jordan, Assr. to The Grasselli Chemical Co. U.S.P. 1,422,866, 18.7.22. Appl., 27.9.19.

See G.P. 339,183 of 1915; J., 1921, 731 A.

Oil-soluble dyestuffs. E.P. 182,497. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood cellulose and cotton cellulose; Comparison of ——. S. A. Mahood and D. E. Cable. J. Ind. Eng. Chem., 1922, **14**, 727—731.

A large number of samples of wood cellulose and cotton cellulose, varying from the raw material to severely cooked and highly bleached pulps, were tested for matter soluble in water and in alkali, acetic acid by hydrolysis, ether-soluble matter, pentosans, furfural, lignin, α-, β-, and γ-cellulose, etc. It was found that the wood-cellulose most nearly approaching cotton-cellulose is obtained by re-cooking "easy bleaching" sulphite pulp with soda, and bleaching with 2% of bleach. Such treatment, however, is uneconomic owing to the low yield. To prepare wood cellulose suitable for esterification it seems probable that acid cooking is preferable to alkali cooking, and that bleaching is a very efficient method of removing non-cellulose material. It is questionable whether wood cellulose for this purpose should be expected to conform to specifications for cotton cellulose in view of radical differences in chemical composition.—C. I.

Jute half-stuff and beaten pulp; Changes during storage of ——. E. W. L. Skark. Papierfabr., 1922, **20**, 881—886, 917—922, 957—962.

The colour and character of jute half-stuffs differ considerably according to whether the bagging has been boiled with lime or with caustic soda and according to the degree of digestion. Bagging boiled with lime bleaches to a bright yellow colour, whereas that boiled with caustic soda has a dull brownish-yellow colour unless the degree of digestion has been so complete that a full white is obtained. The behaviour of the different types of half-stuff in the beating operation may be influenced by the length of time the material has remained in the drainer chests. This influence has been studied by determination of the rates of draining of the beaten stuff by the author's method (J., 1913, 1103; 1922, 9 A). Taking half-stuffs prepared by boiling with lime, whether boiled for a short time with a little lime or a long time with a large quantity, little or no difference could be detected in the behaviour of the pulps in beating, and prolonged storage in the drainers had little influence. In the case of half-stuff lightly boiled with caustic soda, the colour of the bleached pulp, already duller than that of the jute boiled with lime, tended to become still duller during storage. In this case the influence of prolonged storage on the beating was perceptible. With jute boiled for a longer time and with a more concentrated caustic soda solution, the influence of storage on the beating qualities was pronounced, in that the half-stuff became more "mellow" and worked much "softer" in the beating. This beneficial influence of storage, however, reaches a maximum after 2—3 weeks, and no further mellowing is obtained by more prolonged storage. Jute boiled with caustic soda with the addition of sodium sulphide is capable of being bleached to a full white; the mellowing influence of storage is observed also in this case. Storage of the fully beaten pulps in the stuff-chest in the presence of a large excess of water was also found to have a powerful "softening" influence, such that the pulps became progressively slower in draining on the wire until destructive putrefaction set in. This change was more rapid the greater the original degree of beating.—J. F. B.

Rushes as material for board making. C. Uhlemann. Papierfabr., 1922, **20**, 962—965.

Bulrushes (*Typha*) and common reeds (*Phragmites*) in the mixed condition, as harvested, are being utilised at Freiberg, Saxony, as raw material for millboards and various types of cardboards. Photomicrographs of the pulps show that the digestion and separation of the ultimate fibres and vessels are complete, and with a yield of over 30% of useful pulp the economic conditions are stated to be favourable. The manufacture of white printing papers has not yet been undertaken, but the possibilities are promising.—J. F. B.

Lignin and lignosulphonic acid; Oxidation of methyl ethers of ——. E. Heuser and S. Samuelsen. Cellulosechem., 1922, **3**, 78—83.

By repeated treatments with methyl sulphate and 10% sodium hydroxide at 65°—70° C. the methoxyl value of lignosulphonic acid was raised from 13·07 to 25·43% and that of lignin isolated by Willstätter and Zechmeister's method (*cf.* J., 1913, 822) from 14·15 to 26·05%. These methoxylated products were oxidised by alkaline permanganate cold and at 90° C., also by alkali peroxide at 45° C., in the hope of obtaining some oxidation product having a constitutional relationship to the original lignin. Nothing characteristic, however, could be isolated. In the oxidation of methyl-lignin by alkaline permanganate, only 55·65% of the original carbon could be accounted for, 44·76% in the form of carbon dioxide and 10·69% in the form of oxalic acid. Volatile acids calculated as acetic acid amounted only to 0·9% of the material taken. (*Cf.* J.C.S., Sept.) —J. F. B.

Unfermented sugars in spent washes from saccharified wood. Pringsheim. *See* XVIII.

Patents.

Kapok and other fibres; Method to render —— incombustible. R. C. Valls. U.S.P. 1,422,242, 11.7.22. Appl., 1.6.20.

Kapok and other fibres having an impermeable outer cuticle are rendered permeable by treatment with a volatile solvent of low boiling point, such as alcohol, and are then rendered fireproof by treatment with ammonium phosphate.—A. J. H.

Cellulose material [plastic masses]; Manufacture of ——. Köln-Rottweil A.-G. E.P. 156,095, 22.12.20. Conv., 30.12.19.

Nitrocellulose is mixed with tri-orthocresyl ester (phosphate) and *p*-toluenesulphonic acid amyl ester, with the addition of materials, such as cork, sawdust, peat and suitable colouring or filling substances, and the whole is pressed or rolled while hot into an integral mass which can be used for floor covering etc. (Reference is directed, under Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 154,157.)—J. F. B.

Bast fibres; Retting process for ——. A. Herzog and P. Krais. G.P. 346,828, 22.1.21.

In a warm water retting process with slow circulation of the retting water, alkali carbonate or bicarbonate or a mixture of the two is added to the retting water so that this is kept neutral or faintly alkaline.—H. C. R.

Artificial threads, films, and plastic material; Process for manufacturing ——. R. J. Löffler. G.P. 346,832, 16.10.19.

The lignoproteins obtained from proteins and sulphite-cellulose waste lye are added to solutions of cellulose compounds and the mixture spun or moulded, precipitated, and hardened. Alternatively, one component of the lignoprotein may be added to the cellulose solution and the other to the precipitating bath. Fats, oils, dehydrating agents, or filling materials may be incorporated with the lignoproteins. To obtain a patent leather finish by means of the lignoproteins they are dissolved in ammonia and if necessary coloured. —H. C. R.

Millboard and similar substances; Manufacture of —— [using tanyard refuse]. A. T. Masterman. E.P. 182,884, 6.4.21.

Waste wattle bark or other tanyard refuse is crushed for 20 to 30 mins. in an edge runner in the presence of a solution of sodium carbonate or other alkali, and then, after admixture with about 20—30% of waste paper pulp, is beaten for about 2 hrs. with water at 45°—50° C. Engine size and alum, or gelatin alone, are added to the pulp during the beating process, and after leaving the beater the pulp is manufactured into board by hand or in machines. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1994 of 1871, 2619 of 1872, 2672 of 1881, 1004 of 1883, and 9571 of 1900.) —L. A. C.

Dehydrating plastic and other materials [e.g., paper]; Method of ——. R. J. Marx. E.P. 183,097, 1.3.22.

A sheet of the material, *e.g.*, paper, is passed over a series of suction boxes, each providing a different degree of suction and together comprising a continuous zone of uninterrupted suction. The amount of suction is sufficiently low to avoid the formation of any moisture-impeding layer in the material, and preferably increases in successive boxes, so that superposed layers of the material are successively dehydrated.—H. H.

Paper; Process for sizing —— in the hollander. G. Muth. G.P. 349,595, 15.10.14.

Coumarone- and indene-resins or similar products are emulsified with alkali resin soaps, or are melted with natural resins and the mixture emulsified with alkali. For example, 1 pt. of colophony is melted with 10 pts. of coumarone-resin and heated until foaming ceases. The mixture is emulsified with alkali, ammonia, or sodium silicate solution to form a resin-size. The resin soap obtained is considerably purer than one obtained direct from pine resin, and is so readily soluble in water that it can be introduced into the hollander without being first dissolved.—H. C. R.

Sulphite-cellulose waste liquor; Process for treatment of ——. F. Gössel. G.P. 352,624, 25.4.20.

The neutralised and clarified liquor is evaporated under reduced pressure, with simultaneous oxidation, objectionable constituents of the lye being thus rendered harmless. The process may be applied to the residue obtained after treatment of the lye for the production of alcohol, and the product is suitable for use as fodder.—A. G.

Fibrous substances [paper pulp] and the like; Apparatus for pressing liquid out of ——. Aktiebolaget Karlstads Mekaniska Verkstad. E.P. 162,648, 8.4.21. Conv., 30.4.20.

Dyeing cellulose acetate. E.P. 182,830 and 182,844. *See* VI.

Bleaching. G.P. 352,845. *See* VI.

Fermentable sugar from wood. G.P. 351,681 and 352,773. *See* XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Mordants. Alumina. W. D. Bancroft. J. Phys. Chem., 1922, **26**, 501—536.

From a critical review of the literature, the following conclusions are drawn:—The actual hydrolysis of aluminium salts is greater with salts of weak acids, but the apparent hydrolysis may be abnormally large in sulphate solutions owing to the coagulating effect of the sulphate ion on the colloidal alumina. Different fibres adsorb alumina to different degrees, wool having a much greater adsorbing power than cotton, and silk being slightly inferior to wool. Owing to this difference in specific adsorption, wool decomposes aluminium salt solutions which are distinctly acid, whilst cotton is effective only in more basic solutions. The substance adsorbed and held firmly is colloidal alumina. Coagulated alumina may be adsorbed to some extent, but it easily rubs off the material. It is probable that in all cases alumina is adsorbed and not a basic salt. The phenomena may be complicated by the fact that the alumina itself will adsorb some sulphuric acid, for example, and that the wool also adsorbs sulphuric acid. If to cotton is added some substance, such as tannin, which adsorbs alumina strongly, then the mordanted cotton is able to take alumina from solutions of aluminium salts which are not decomposed by cotton alone. The increase in the adsorbing power of mercerised cotton is due to a structural difference of the cotton fibre. There is no evidence of the formation of any definite compound between alumina and silk, cotton, or wool.—J. F. S.

Textile fibres; Colour absorption from dye liquors by ——. R. Auerbach. Kolloid-Zeits., 1922, **31**, 37—40.

In view of the difference between the states of dispersion of a dyestuff when in aqueous solution and when deposited within a textile fibre, the colour of the dye liquor and that of cotton or wool fabric dyed by means of it, have been compared in the case of about sixty basic, acid wool, and direct cotton dyestuffs. The determination of the shade of the dyed fabric was carried out after drying, but it was shown that the wet dyed fabric could have been used with but small error. In nearly all cases, the fibre had a bathochromic influence, but in the case of Chicago Blue R W and Wool Blue 5 B, its influence was hypsochromic. —A. J. H.

Patents.

Bleaching fibres, textiles, and the like with hypochlorites; Process for ——. Zellstoff-fabr. Waldhof. G.P. 352,845, 11.5.18.

Fibrous material, *e.g.*, sulphite-cellulose, is bleached by treatment, first with acid and then with alkaline, solutions of hypochlorites.—L. A. C.

Dyeing, bleaching and analogous treatment of textile fibres; Process of and apparatus for ——. J., T., and J. Brandwood. E.P. 182,575, 8.4.21.

Textile material in the loose form is conveyed through the machine between two open-woven or meshed, endless travelling belts, which may consist of brattice cloth strengthened by transverse flat stiffening rods. On entering the machine, the conveyor passes around two cylinders having perforated surfaces and arranged within a tank containing dye-liquor. By means of pumps, the liquor is drawn inward through the textile material at one cylinder and forced outward through the material at the other cylinder. The conveyor then carries the material over the perforated top of another tank, where it is subjected to a current of air or suitable liquor passing in either direction, and then into a third tank where it passes over the perforated surfaces of two chambers, and is further subjected to a current of wash water in either direction. Beyond this tank, the two belts diverge and the treated textile material is removed by means of rotary brushes. This machine is suitable for dyeing with sulphur, oxidation, azo, or basic dyestuffs.—A. J. H.

Cellulose acetate or products made therewith; Treatment [dyeing] of ——. *Treatment [dyeing] of union or mixed fabrics [containing cellulose acetate].* R. Clavel. E.P. (A) 182,830, 12.1. and 30.8.21, (B) 182,844, 9.2. and 8.11.21.

(A) Dyestuffs of any class containing hydroxyl, amino, imino, imido, nitro, nitroso, isonitroso, acidylamino, or azo groups, and either no sulphonyl groups, or not more than one sulphonyl group together with two or more of the above groups, are suitable for the direct dyeing of cellulose acetate products, such as artificial silk, films, and the like, which have been prepared by processes in which depolymerisation of the cellulose molecule has been avoided as far as possible. In dyeing with basic dyestuffs, the addition to the dye-bath of salts such as magnesium chloride, stannous chloride, or zinc chloride, which are capable of forming double salts with the dyestuffs, or the use of the dyestuffs in the form of these double salts, gives even dyeings fast to light and washing. Dyestuffs insoluble in water, such as water-insoluble Induline, can be applied in aqueous suspension, *e.g.*, in an aqueous foam bath prepared as described in E.P. 102,310 (J., 1917, 80). After dyeing, the material is treated in a bath containing formic acid or acetic acid and an oil emulsion consisting of olive oil and olive oil soap. (Reference is directed, in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Acts, 1907 and 1919, to E.P. 176,535; J., 1922, 325 A.) (B) The cellulose acetate present in mixed fabrics containing cellulose acetate fibres and other natural or artificial fibres is dyed as described in (A), and if the dyestuffs employed are not appropriate for the other fibres present, the fabric is also dyed with another dyestuff appropriate for the other fibres. The two dyestuffs may be applied in separate baths, or both may be present in the one bath.—L. A. C.

Dyeing skins, hairs, and the like; Process for ——. A. G. Bloxam. From Akt.-Ges. für Anilin-Fabr. E.P. 183,078, 31.10.21.

See U.S.P. 1,416,646 of 1922; J., 1922, 543 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Manufacture of ——. *The U.S. Government explosives plant C, Nitro, West Virginia.* M. F. Chase. J. Ind. Eng. Chem., 1922, **14**, 677—681.

This plant, erected in 1918, comprised 96 3-ton retorts for the decomposition of sodium nitrate. The nitre was mechanically handled throughout and was dried, before use, in gas-fired rotating steel cylinders. " Bleach pots " packed with rings were interposed between the pots and condensers, in which the condensed acid met the ascending vapours, these and all the condensers and connexions being made of acid-resisting iron. The condensers consisted of a series of return bends cooled with sprays. To each set of 24 retorts was connected a series of 18 stoneware towers, 15 ft. high and 30 in. diam., fed with water for absorbing the uncondensed gases. The time of working off one charge was 12 hrs., the maximum temperature obtained in the retorts 250° C., and the mean overall efficiency 92%.—C. I.

Nitric acid solutions; Concentrating dilute ——. C. D. Carpenter and J. Babor. Chem. and Met. Eng., 1922, **27**, 121—124.

A DETAILED series of determinations of the composition of a boiling nitric acid solution and of the distillate therefrom during concentration from 5% HNO_3 to 68% HNO_3 in an apparatus from which any fractionation is excluded, is given. The quantity of acid passing over into the distillate on simple distillation from 20% up to 55% concentration is 33·3% of the quantity originally present, but on further distillation up to 65% concentration, 69% of the acid passes over. While two distillations to 55% give a recovery of 90% of the acid, two distillations up to 65% give a recovery of only 52%. It is therefore concluded that in the pre-concentration of nitric acid by fractionation it is not advisable to go above 55—60% concentration, the extra fractionation required to reach 65% being out of all proportion to the gain. From the curves which summarise the above-mentioned data the composition of the vapour above a boiling nitric acid solution of any strength is deduced. Results so obtained are compared with those of Pascal (J., 1921, 506A) and of Berl and Samtleben (J., 1922, 461 A), and the apparatus and methods of calculation of these observers are criticised.—C. I.

Barium sulphuric acid and barium selenic acid. J. Meyer and W. Friedrich. Z. physik. Chem., 1922, **101**, 498—503.

SULPHURIC acid of 97·86% concentration dissolves 14·91 g. of barium sulphate per 100 c.c. at 25° C., and from the solution crystals of barium sulphuric acid, $H_2[Ba(SO_4)_2]$, separate. Similarly a concentrated solution of selenic acid dissolves barium selenate and deposits crystals of barium selenic acid, $H_2[Ba(SeO_4)_2]$. (*Cf.* J.C.S., Sept.)—J. F. S.

Nitrogen fixation by the cyanide process. F. E. Bartell. J. Ind. Eng. Chem., 1922, **14**, 699—704.

INVESTIGATIONS on cyanide synthesis by the Bucher process were carried out with 4-in. retorts holding 8 lb. of briquettes and with 10 ft. by 8 in. continuous retorts capable of making 7—8 lb. of cyanide per hr. It was shown that Bucher's claim that serious chemical difficulties did not exist and that the precise nature of the coke used made little difference was justified. Producer gas is, however, inadmissible as a source of nitrogen, owing to the harmful effect of carbon monoxide. The difficulty consists in the close correlation of the mechanical treatment with the progress of reactions which are easily reversible. A temperature of 1050° C. is best in the retort. The formation of cyanide is most active in the lower portion of the retort, but it gradually distils upwards, while in the upper part the carbon monoxide generated tends to reverse the reaction. For success it is therefore necessary to maintain such a supply of nitrogen that the partial pressure of carbon monoxide is as low as possible. The mixture briquetted consisted of 50% of petroleum coke, 38% of sodium carbonate, and 12% of iron, previous to the oxidation of the last. The nitrogen used was obtained by the slow combustion of coke and removal of carbon dioxide from the combustion products. A series of cost estimates based on U.S. prices in 1918 give the cost per lb. of NH_3 by this process at 27—37 cents. —C. I.

Sodium bicarbonate; Preparation of ——. E. Toporescu. Comptes rend., 1922, **175**, 268—270.

A STUDY similar to that originally made at 15° C. (J., 1922, 325 A) of the equilibrium of the four salts, sodium chloride, sodium bicarbonate, ammonium chloride, and ammonium bicarbonate, with their saturated solutions has been made at 35° C. and 50° C. The geometrical representation of the results obtained by means of a Le Chatelier diagram enables a calculation to be made of the theoretical yield, that is to say, the proportion of sodium chloride transformable into bicarbonate for a solution of any given initial composition. The course of the industrial preparation of sodium bicarbonate does not run parallel with this owing to the varying temperature of the salt solutions, but nevertheless the results will indicate whether it is necessary to add water to the original sodium chloride solution in order to avoid precipitation of ammonium bicarbonate, or whether more solid salt must be added in order to obtain the theoretical yield. —G. F. M.

Calcium cyanamide; Formation of —— from calcium ferrocyanide. H. Pincass. Chem.-Zeit., 1922, **46**, 661.

ON heating hydrated calcium ferrocyanide steadily for an hour to a maximum temperature of 690°—700° C., a black, magnetic, friable mass is obtained which contains no ferrocyanide but about 80—90% of the theoretical quantity of calcium cyanamide that should be formed according to the equation: $Ca_2Fe(CN)_6 = N_2 + FeC_2 + 2CaCN_2 + 2C$. With higher temperatures and longer heating the yield is greatly reduced. No calcium cyanamide is formed by heating an intimate mixture of 1 molecule of potassium ferrocyanide and 1 molecule of lime at temperatures up to 1000° C.; the reaction product contains, in this case, only cyanide.—A. R. P.

Calcium; Determination of —— in natural phosphates. R. Meurice. Ann. Chim. Analyt., 1922, **4**, 198.

THE phosphate is treated with mineral acid, the silica is removed and the iron and aluminium are separated by precipitation as phosphates in acetic acid solution. The filtrate is then neutralised with ammonia, treated with 20 c.c. of 20% hydrochloric acid and 30 c.c. of 4% ammonium oxalate, warmed, and 10% ammonium acetate added at a rate of about 30 drops per minute. A granular precipitate of calcium oxalate is thus obtained and this is collected, washed and ignited as usual. Test analyses carried out on known quantities of calcium in the presence of phosphates and magnesium sulphate in large excess gave very accurate results. —H. C. R.

Calcium arsenate manufacture. H. W. Ambruster. Chem. and Met. Eng., 1922, **27**, 159—160.

IN all plants in the United States at present making calcium arsenate, and in those likely to be erected in the immediate future, the process used consists in oxidising arsenic trioxide with nitric acid and neutralising with lime. Earlier plants working with small units employed earthenware pots with hand agitation and an earthenware absorption tower for absorbing nitrous fumes. The more modern plants have large silicon-iron nitrating vessels with mechanical feed of arsenic and mechanical stirrers, and acid-proof brick absorption towers. The earlier filter-press and oven for drying the arsenate are replaced by a rotary drum dryer which saves much labour while using no more steam.—C. I.

Solubility of gases in liquids. B. S. Neuhausen. J. Phys. Chem., 1922, 26, 553—557. (*Cf.* J., 1922, 249 A.)

The solubility of ammonia, carbon dioxide, sulphur dioxide, and hydrogen chloride in methyl alcohol and ethyl alcohol as well as in water can be represented by the formula $V = K(P\sigma/P_0)^{1/n}$, where V is the volume of liquefied gas dissolved per gram of water, P the equilibrium pressure, σ the surface tension, and P_0 the vapour tension of the liquefied gas at the temperature of measurement. The values of K for the three solvents water, methyl alcohol, ethyl alcohol are: NH_3, 0·49, 0·205, 0·108; HCl, 1·05, 1·23, 0·979; SO_2, 0·012, 0·04, 0·04; CO_2, 0·006, 0·0126, 0·0103; and the corresponding values for 1/n are: NH_3, 0·69, 0·69, 0·71; HCl, 0·12, 0·062, 0·065; SO_2, 0·91, 1·20, 1·00; CO_2, 0·33, 0·07, 0·055. —J. F. S.

Sodium silicate solutions; Electrolysis of ——. J. F. Spencer and K. Proud.. Kolloid Zeits., 1922, 31, 36—37.

Orthosilicic acid may be prepared by the electrolysis of a 50% solution of sodium silicate in a divided cell using a heavy anode current density. The cathode employed was a platinum dish of 7·5 cm. diam. and this contained a small porous pot which held the anode, a coil of platinum wire of 1·80 sq. cm. surface. A current of 9 amps. was used and this fell rapidly until no current passed, due to the formation of an insulating layer of orthosilicic acid on the anode. On bending the wire the deposit fell away and the current again passed. The product is glass-like in appearance, entirely insoluble in water, and stable in the air.—J. F. S.

Reactions in fused salt media. Solvolysis. J. F. G. Hicks and W. A. Craig. J. Phys. Chem., 1922, 26, 563—576.

Lead, silver, and barium chromates and lead oxide when dissolved in molten sodium chloride or an equimolecular mixture of sodium and potassium nitrates, undergo solvolysis in the same way that lead chromate undergoes hydrolysis in water. In the nitrate fusion the solvolysis of lead chromate occurs to the greatest extent and that of silver chromate to the least. The solvolysis of lead oxide in fused sodium chloride is practically complete at 850°—870° C.; that of silver chromate is complete at this temperature and proceeds more rapidly. (*Cf.* J.C.S. Sept.)—J. F. S.

Selenium dioxide; Preparation of ——. J. Meyer. Ber., 1922, 55, 2082—2084.

Selenium in quantities of 60—75 g. is heated to its melting point in a porcelain boat placed in a wide hard glass tube; a very rapid current of oxygen which has been passed through fuming nitric acid is led over it, causing the molten selenium to burn with a brilliant blue flame and to give a sublimate of selenium dioxide, the purity of which increases with increasing rate of flow of oxygen. The product, which contains small quantities of oxides of nitrogen, is purified by being sublimed in the same tube in a current of pure oxygen. To avoid loss of material, the tube is connected with a doubly tubulated vessel of two litres capacity in which the final traces of the dioxide are deposited. The combustion of 60—70 g. of selenium can be effected in about 1¼ hours. (*Cf.* J.C.S., Sept.)—H. W.

Carbon suboxide; Preparation of —— on a larger scale and the properties of pure carbon suboxide. E. Ott and K. Schmidt. Ber., 1922, 55, 2126—2130.

Carbon suboxide is prepared in 41% yield by leading the vapours of diacetyltartaric anhydride, boiling under diminished pressure, over a platinum wire heated to bright redness. The apparatus, which permits the manipulation of a charge of 250 g. of the anhydride in 6—8 hrs., is fully figured and described. As regards yield and cost of material the process is superior to that of Stock and Stoltzenberg (J., 1917, 645) and has the further advantage that the carbon suboxide so prepared can be preserved for long periods without change in sealed tubes, whereas the product obtained with the help of phosphorus pentoxide rapidly polymerises, probably owing to the presence of traces of phosphorus oxide. (*Cf.* J.C.S., Sept.) —H. W.

Ozone. E. H. Riesenfeld and G. M. Schwab. Ber., 1922, 55, 2088—2099.

By the use of micro-methods the isolation of pure ozone has been effected by condensing ozonised oxygen in small glass bulbs surrounded by liquid air and subsequent fractionation of the dark blue condensed liquid (which contains initially about 30% of oxygen). It has m.p. −250° C., b.p. −112·3° C., critical temperature −5° C., density 1·784 at −182° C. Liquid ozone is not completely miscible with liquid oxygen at all temperatures, the critical temperature of solubility being −158° C. The explosive decomposition of ozone is extremely sensitive to catalytic influences, but if these are excluded it is unexpectedly stable. According to Warburg's calculation, the half-life period of pure ozone at 16° C. is 167 hrs., whereas it is found that under certain conditions a period of several weeks elapses before decomposition has proceeded to this extent. No evidence of the existence of Harries' oxozone has been obtained. (*Cf.* J.C.S., Sept.)—H. W.

PATENTS.

Sulphuric acid; Method of and apparatus for the manufacture of ——. A. Helbronner and P. Pipereaut. E.P. 157,281, 10.1.21. Conv., 29.4.18.

The cooling action of the chamber walls in the usual lead chamber process is essential for the normal reaction in this process, which consists of the formation and decomposition of nitrosylsulphuric acid. Intensive working, however, involves the formation of nitrogen peroxide and nitric acid and for the reaction with these compounds as oxygen-carriers cooling is not required. An apparatus designed for intensive working consists of a series of cells of volvic lava arranged in an ascending cascade, with the hot burner gases entering at the bottom. The lower ones serve simply as a concentrator. Nitric acid is introduced into the sixth, and nitrous vitriol, dilute acid and water into the eighth cell. After passing through 22 cells the gases pass up water-cooled vertical lead pipes to a series of 6 towers of small diameter in which condensation is completed and thence to a Gay Lussac tower.—C. I.

Chlorosulphonic acid; Method of making ——. T. L. Briggs (I. M. Briggs, extrix.), Assr. to General Chemical Co. U.S.P. 1,422,335, 11.7.22. Appl., 4.10.21.

Controlled volumes of hydrochloric acid and "contact gas" (gas from the contact process of making sulphuric acid) are passed through a mixing chamber and thence through a long passage of restricted diameter. The liquid chlorosulphonic acid is withdrawn.—A. G. P.

Phosphoric acid; Process of producing ——. E. W. Guernsey and J. Y. Yee. U.S.P. 1,422,699, 11.7.22. Appl., 28.6.21.

Phosphate rock, silicious material, and carbonaceous material are intimately mixed in such proportions that the molecular ratio of the combined

calcium oxide to the silica will be 1:1. The mixture is made into briquettes and heated at a temperature not exceeding that of incipient clinkering until all the phosphorus has been expelled. The phosphorus is recovered in the form of oxides.
—H. R. D.

[Hydrochloric acid; Manufacture of —— in process for the] extraction of potassium compounds. W. Glaeser, Assr. to Potash Extraction Corp. U.S.P. 1,422,848, 18.7.22. Appl., 7.6.18.

CALCIUM chloride is heated with alunite in the presence of steam, and the hydrochloric acid evolved is collected.—L. A. C.

Nitrogen oxides; Recovery of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 298,845, 22.9.15.

NITROGEN oxides are recovered from the gases produced by the catalytic oxidation of ammonia by passing the gases through coolers; the gases pass through the coolers in less than 1 second.—A. B. S.

Ammonia; Process for manufacture of ——. Norsk. Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 159,878, 1.3.21. Conv., 9.3.20.

IN the synthesis of ammonia, using iron, nickel, cobalt, chromium, or manganese, as contact substances, alkali cyanides are employed as activators.
—H. R. D.

Ammonia; Synthesis of ——. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 160,811, 29.3.21. Conv., 30.3.20.

THE reacting gases are preheated by contact with the wall of the chamber containing the catalyst, the thermal conductivity of the wall being of such value that under normal working conditions the gases reach the catalyst at the lowest temperature permitting of the normal maintenance of the reaction. To attain the desired object the tube containing the catalyst is made of material of low thermal conductivity or of steel covered with heat-insulating material. The process is especially applicable when very high pressures are used.
—H. R. D.

Magnesium chloride; Manufacture of ——. V. M. Goldschmidt. E.P. 161,165, 9.3.21. Conv., 29.3.20.

MAGNESIUM oxide is chlorinated in the presence of sulphur or sulphur chlorides free from oxygen at 200°—500° C., according to the following equation:

$$2MgO+2Cl_2+S=2MgCl_2+SO_2.$$

—H. R. D.

Aluminium oxide; Process of reducing —— [to form carbide or aluminium alloys]. L. Burgess. E.P. 182,609, 27.4.21.

ALUMINIUM oxide or material containing it, *e.g.*, bauxite, is intimately mixed with a pasty carbonaceous material, such as pitch or tar, with or without the addition of further solid carbonaceous matter, and the mixture is coked, whereby finely divided aluminium oxide is obtained intimately mixed with carbon. This matrix is broken up and packed around carbon electrodes between which an arc is produced, whereby aluminium carbide is formed. Products containing varying percentages of metallic aluminium or aluminium alloys or carbides of other metals may be obtained by varying the quantity of carbon and adding other oxides to the original mixture.—A. R. P.

Caustic soda; Manufacture of ——. Courtaulds, Ltd., and R. O. Jones. E.P. 182,661, 11.6.21.

CAUSTICISING is effected in two stages according to the equations,

$$Ca(OH)_2+Na_2CO_3\rightleftarrows 2NaOH+CaCO_3, \text{ and}$$
$$Ca(OH)_2+2Na_2CO_3+xH_2O\leftrightarrows 2NaOH+Na_2CO_3,CaCO_3,xH_2O$$

In the first stage the concentrations are so chosen that little or no double carbonate is formed, and after completion of this stage the liquor is separated, preparatory to the second stage, when more sodium carbonate and lime are added to the liquor and a further conversion to caustic soda takes place. In this manner a liquor is readily obtained containing about 20% of caustic soda and 6% of sodium carbonate.—H. R. D.

Alkali hydroxides; Production of —— from alkali sulphates. K. Kaiser. G.P. 352,714, 20.4.20.

ALKALI hydroxides are produced by passing a mixture of hydrogen and steam over heated alkali sulphate. A substance, such as calcium hydroxide, which evolves water on heating, or a metallic oxide, such as ferric oxide, which is reduced by hydrogen, may be added to the sulphate. Alkali carbonate may be produced in a similar manner by adding carbon monoxide to the mixture of hydrogen and steam.—A. B. S.

Ammonia-soda process; Method of conducting the ——. E. E. Arnold, and P. St. Clair, jun., Assrs. to The Nitrogen Corp. U.S.P. 1,423,510, 25.7.22. Appl., 11.3.20.

A COMPRESSED gas is expanded in proximity to, but separated from, a body of ammoniated brine, to absorb the heat generated by the reactions in the ammonia-soda process.—H. R. D.

Caliche; Treatment of —— [for extraction of sodium nitrate]. W. Broadbridge, E. Edser, and W. G. Sellers. E.P. 182,859, 9.3. and 6.9.21.

IN existing methods of extraction of caliche an incomplete yield is obtained because it is only possible to crush the crude material coarsely, otherwise slimes are produced which can neither be settled nor filtered. If, however, such slimes are agitated with aeration, especially with addition of a flocculating agent, they are capable of filtration. Suitable flocculating agents are fatty acids, soap, wood tar, glue, and sodium silicate or aluminate, and the quantity required may be no more than 1¼ lb. per ton of finished nitrate. The hot liquor passes down through a mass of caliche, crushed as finely as desired, resting on the false bottom of the extraction vessel, then upwards through the adjacent stirring vessel, to which the flocculating agent is added, and then back to the extractor. The circulation is continued until the bottom liquor is clear, the caliche itself acting as filter. A number of such pairs of apparatus are combined in a set in the usual way. The residues may be washed as desired if the surplus water introduced is afterwards evaporated.—C. I.

Sulphate of ammonia; Neutralisation and drying of ——. G. Weyman. E.P. 183,089, 1.12.21.

POWDERED dry ammonium carbonate is fed mechanically into the centrifuge during the drying of the acid salt, after the bulk of the mother liquor is removed. The greater part of the free acid is to be found on the inner surface of the mass of crystals and distribution of the neutralising agent is assisted by the carbon dioxide evolved, which also dries the hot crystals. To avoid corrosion of the basket the salt should be discharged before neutralisation is complete, and neutralisation completed during discharge. By this process a neutral salt containing over 25·50% NH_3 can be made without special drying.—C. I.

Calcium hypochlorite; Process for production of stable compounds of ——. Chem. Fabr. Greisheim-Elektron, H. S. Schultze, G. Pistor, and H. Reitz. E.P. 182,927, 13.4.21.

CALCIUM hypochlorite compounds produced by chlorinating calcium hydroxide in water are stabilised by removing the calcium chloride from the crystals of basic calcium hypochlorites or mixed basic and neutral calcium hypochlorites, and drying the crystals at a temperature up to 110° C. either *in vacuo* or at ordinary pressure. The crystalline products thus formed contain over 40% of available chlorine.—H. R. D.

Calcium carbide; Method of manufacturing ——. W. B. Rogatz, Assr. to Farmers Standard Carbide Co. U.S.P. 1,422,135, 11.7.22. Appl., 5.5.21.

The material is fed through the wall of the furnace and the side crust, above the already molten material, but below the top crust.—H. R. D.

Sulphur dioxide; Process of gassing liquors with ——. F. M. Allen, Assr. to General Chemical Co. U.S.P. 1,422,327, 11.7.22. Appl., 29.4.20.

Air is introduced under a pressure not much greater than that of the atmosphere into a relatively small chamber containing molten sulphur. By controlling the velocity of the inflowing air the temperature of the mixed gases leaving the chamber is maintained at about 550° F. (287° C.), and these gases are led into a body of liquid, the dimensions of the chamber, plus all the air and gas conduits, being such that the gases from the chamber are propelled with sufficient force to enable them to overcome the resistance of the liquid into which they are introduced.—H. R. D.

Oxysalt composition. C. Catlett. U.S.P. 1,422,337, 11.7.22. Appl., 3.8.21.

Solid lime and solid calcium chloride, both in a finely divided condition, are mixed together " under reacting conditions."

Aluminium chloride; Process of making ——. H. D. Gibbs, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,422,560, 11.7.22. Appl., 19.5.21.

Aluminium chloride is prepared by treating aluminium with chlorine below 0° C.—L. A. C.

Aluminium chloride; Manufacture of ——. F. W. Hall, Assr. to The Texas Co. U.S.P. 1,422,568, 11.7.22. Appl., 20.9.21.

Chlorine, sulphur, and powdered alumina are caused to react under conditions suitable for the production of aluminium chloride.—L. A. C.

Potassium salts; Method of extracting —— *from bitterns.* I. F. Harlow, Assr. to The Dow Chemical Co. U.S.P. 1,422,571, 11.7.22. Appl., 27.11.16.

A bittern, containing potassium carbonate, other potassium salts, and sodium salts, is concentrated approximately to saturation point, and a quantity of calcium chloride chemically equivalent to the potassium present is added. The solution is heated to about 95° C., whereby calcium carbonate is precipitated and the potassium salts are converted into chloride. The residual solution is concentrated to about ¾ of its former volume, whereupon the sodium salts crystallise out while the solution is still hot, and are separated from the mother liquor. The liquor is then cooled to about 20° C., and practically pure potassium chloride crystallises out from the solution.—L. A. C.

Retort [for production of alkali cyanide]. F. G. Metzger, Assr. to Air Reduction Co. U.S.P. 1,422,878, 18.7.22. Appl., 11.10.17.

An iron retort suitable for the manufacture of alkali cyanides is protected from the effect of oxidising gases at high temperature by an external skin coating of a " base metal alloy."—C. I.

Alkali cyanides; Production of ——. H. Koppers. G.P. 350,628, 3.1.18.

In the production of alkali cyanides by heating a mixture of carbon, alkali salts (chlorides), slag-forming material, and iron or manganese compounds, by means of hot air in a gas producer, the decomposition zone is heated above the b.p. of the alkali cyanide. A portion of the gases is drawn off from this zone, and treated for the recovery of alkali cyanide, while the remainder of the gas, which contains hydrogen chloride, is drawn off from the top of the producer.—L. A. C.

Hydrogen; Manufacture of —— *by partial liquefaction of mixtures of gases containing the same.* L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 175,605, 23.12.21. Conv., 17.2.21.

Water-gas illuminating gas, coke-oven gas, or like gases may be treated by the process. The fraction of the compressed gas utilised for feeding the liquefier is withdrawn from the heat interchanger at a point situated at a distance from the cold end of the interchanger, so that the temperature attained by the hydrogen immediately before subjecting it to expansion is raised to the maximum degree compatible with the attainment of the low temperature, after expansion, necessary to ensure purity of the hydrogen, and at the same time the temperature of the main portion of the gases to be treated, admitted to the separating column, is considerably lowered. If the presence of nitrogen is not undesirable, a certain proportion of cold compressed nitrogen may be added to the compressed hydrogen in the expansion chamber. Hydrocarbon gases may also be added, provided they do not solidify at the temperature obtaining in the expander.—A. G.

Carbon; Method of purifying ——. V. Lenher and F. M. Dorsey, Assrs. to General Electric Co. U.S.P. 1,423,231, 18.7.22. Appl., 18.9.20.

Carbonised material is subjected to the action of selenium oxychloride, then washed with carbon tetrachloride, and the remaining carbon tetrachloride evaporated.—H. C. R.

Arsenical compounds; Manufacture of ——. K. B. Edwards. U.S.P. 1,422,945, 18.7.22, and 1,424,006, 25.7.22. Appl., 22.10.21.

See E.P. 162,747 of 1920; J., 1921, 470 A.

VIII.—GLASS; CERAMICS.

Patent.

Kiln; Gas-fired pottery ——. A. McD. Duckham. U.S.P. 1,423,408, 18.7.22. Appl., 29.12.21.

See E.P. 176,419 of 1920; J., 1922, 328 A.

IX.—BUILDING MATERIALS.

Cement mortars; Relations between voids and plasticity of —— *at different relative water contents.* F. E. Richart and E. E. Bauer. Amer. Soc. Testing Materials, June, 1922. [Preprint.] 20 pp.

Minimum voids in a mortar are determined by taking known volumes of sand and cement (the sp. gr. of both being known), mixing with varying increments of water, and tamping into a counterpoised mould of known volume. The weight of the same volume of mortar for varying amounts of water is thus found, and from the greatest weight the minimum voids can be calculated by a formula (*cf.* Talbot, Proc. Amer. Soc. Testing Materials, 1921, 21, 944). About the same number of determinations are required as for the Vicat test. Tables and curves of Vicat and mortar-void tests on neat cement show an approximation of basic water content (amount of water producing minimum voids) and water of normal consistency. From results of a number of tests on sand mortars and neat cements, basic water content appears to coincide in general with water content giving maximum strength (compression and tensile). Basic water content is suggested as a standard for comparative strength tests on mortars. Curves are plotted showing the close relation between water values obtained from a basic water-content curve and from Feret's and Taylor's formulæ for normal consistencies. Under certain conditions the values from the first appear to be more applicable than those from the older formulæ. The results of "slump" and "flow" tests (*i.e.*, workability) in relation to minimum void are also shown graphically.—J. B. P.

Plaster; Dispersoid chemistry of ——. Investigation on anhydrite. H. Neugebauer. Kolloid-Zeits., 1922, 31, 40—45.

The dehydration of the various hydrates of calcium sulphate was never complete at 115° C. or slightly above, and in no case could the water of crystallisation be reduced below 4%. The common dihydrate loses its water of crystallisation at 102° C. considerably more slowly and less completely than the other forms, probably because of the size of the crystals. The commercial product, anhydrasite, prepared by the hydration of natural anhydrite exhibits on dehydration, a behaviour analogous to that shown by van't Hoff's plaster (Z. physik. Chem., 1903, 45, 3), prepared in the form of fine needles, by hydration of plaster of Paris with about 20 times its weight of water, with occasional agitation, and it is affected in the same way as plaster of Paris by the addition of alum. A further technical product, leucolith, from its viscosity measurements shows no combination with water. The behaviour in this case is analogous to that of flooring plaster, the setting of which is due to the presence of free lime. (*Cf.* J.C.S., Sept.)—J. F. S.

Phenols from low-temperature tar; Utilisation of —— for wood preservation. F. Peters. Brennstoff-Chem., 1922, 3, 198.

The phenols from low-temperature tar consist for the most part of xylenols and higher homologues. A low-temperature tar was freed from constituents boiling below 210° C. by distillation, and the residue was mixed with an equal quantity of neutral impregnating oil prepared from ordinary coal tar. Pine wood chips were then soaked in a solution of this mixture in acetone. Varying concentrations were used and after evaporation of the acetone the chips were exposed to the action of *Coniophora cerebella* in suitable glass vessels under conditions favourable to putrefaction. Similar experiments were carried out with the impregnating oil alone, free from tar acids. After several months the chips were removed from the vessel and examined for decay. A mixture of 1 pt. of low-temperature phenols and 1 pt. of impregnating oil had the same fungicidal action as the impregnating oil alone.—A. G.

Patent.

Cementing and protecting composition. L. E. Barringer, Assr. to General Electric Co. U.S.P. 1,423,985, 25.7.22. Appl., 18.11.19.

See E.P. 159,421 of 1920; J., 1921, 266 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Chromium; Rapid method for the determination of —— in nickel-chromium steels. W. Hild. Chem.-Zeit., 1922, 46, 702—703.

The steel is dissolved in nitric acid and the solution evaporated with sulphuric acid. The chromic sulphate is oxidised to chromic acid with an excess of potassium permanganate, and the excess is destroyed by heating with manganese sulphate. The filtered solution is treated with an excess of standard ferrous sulphate and eventually titrated with permanganate. As a control the iron may be removed from a chloride solution by means of ether, the chromium precipitated with ammonia, the precipitate dissolved in sulphuric acid, and the assay finished as above.—A. R. P.

Ferrotungsten; Rapid analysis of ——. L. Losana and E. Carozzi. Giorn. Chim. Ind. Appl., 1922, 4, 299—301.

The following method, occupying less than two hours, gives accurate results, and is especially suitable for the rapid industrial control of the proportion of tungsten in iron alloys and tool steels. The alloy is powdered and 0·5 g. heated carefully in a platinum dish with 10 c.c. of nitric acid (sp. gr. 1·2) and about 2 c.c. of hydrofluoric acid until solution is complete, 5 c.c. of concentrated sulphuric acid being then cautiously added and the dish heated on asbestos card until dense white fumes have been evolved for some minutes. The hydrofluoric acid having been removed in this way, the liquid and the adherent precipitate are transferred to a porcelain basin and there boiled briskly for 10 mins. with 15 c.c. of concentrated hydrochloric acid. After filtration, the precipitate is washed with hot 5% hydrochloric acid solution until the filtrate ceases to contain iron, the wet filter paper and precipitate being then calcined in a platinum crucible and the residual WO_3 weighed. Alternatively the latter may be washed with potassium chloride solution until neutral and then titrated with alkali solution. The filtrate may be used for the estimation of the iron, manganese, phosphorus, calcium, aluminium, etc., in the usual way.—T. H. P.

Molybdenum in tungsten; Estimation of small amounts of ——. D. Hall. J. Amer. Chem. Soc., 1922, 44, 1462—1465.

Small amounts of molybdenum in tungsten may be determined as follows: One gram of the alloy is dissolved in a mixture of nitric acid and hydrofluoric acids and the solution evaporated with sulphuric acid. The yellow oxides are dissolved in sodium hydroxide and the solution transferred to a 200 c.c. separating funnel, acidified with sulphuric acid, and diluted so that 1 c.c. contains about 0·1 mg. of molybdenum. The volume is made up to 150 c.c., 0·5 g. of solid potassium xanthate and a few drops of 1:3 sulphuric acid added, and the mixture shaken thoroughly. About 10 c.c. of chloroform is added and the whole shaken for several minutes. The highly coloured chloroform layer settles at the bottom and is run into a second funnel for washing. The original solution is repeatedly treated with potassium xanthate, acid, and chloroform until the chloroform layer is colourless, each portion of the chloroform solution being added to the first. The chloroform solution of molybdenum xanthate is washed several times with water, run into a 150 c.c. beaker, and evaporated to dryness. The residue is heated and converted into a mixture of oxide and sulphide. This is dissolved in nitric acid, evaporated with sulphuric acid and molybdenum sulphide precipitated by passing hydrogen sulphide into the hot solution, made alkaline with sodium hydroxide. The solution is then slowly acidified with dilute sulphuric acid, the precipitate filtered off, washed with hot water, and ignited to trioxide. The method is extremely good for small quantities of molybdenum.—J. F. S.

Chromium; Determination of —— in metals. W. Löffelbein. Chem.-Zeit., 1922, **46**, 679.

Small quantities of chromium, such as remain in the alloy after deoxidising nickel bronzes, may be accurately determined as follows:— 3—5 g. of the turnings is dissolved in *aqua regia,* the solution is evaporated to dryness, the residue treated with dilute hydrochloric acid, and the liquid saturated with hydrogen sulphide and filtered. The filtrate is boiled, oxidised with bromine, and treated with a slight excess of ammonia. The precipitate is collected, ignited, and fused with sodium peroxide. The melt is leached with water and the chromium determined iodometrically in the solution after filtration.—A. R. P.

Osmiridium; Notes on ——. J. R. Thurlow. J. Chem. Met. Soc. S. Afr., 1922, **22**, 209—210.

Osmiridium occurs in the gold ores of the Eastern Rand (Transvaal) to the extent of 1 oz. to 5000—15,000 tons, and during treatment of the ores it accumulates in the " black sands," which consist chiefly of pyritic minerals with some ilmenite and chromite. These concentrates are treated on a batea to obtain a product containing about 40% of osmiridium, which is further concentrated to 90—95% by careful hand-panning. All the tailings are further treated on small canvas tables, and the concentrates are finally cleaned by treatment with acids. Analyses of a number of concentrates and of a typical " black sand " are given.—A. R. P.

Copper-zinc alloys; Electrolytic separation of ——. P. Weise. Z. Elektrochem., 1922, **28**, 327—341.

Copper may be prepared from bronze, containing up to 20% of tin, by electrolysing, at 75° C., a solution of 15% of copper sulphate in 5% sulphuric acid, using a copper cathode, 34×34 cm., between two bronze anodes, 36×36 cm., and a direct current of 150 amps. per sq. m. The copper is deposited quite pure and the tin falls as a powder to the bottom of the cell, but still contains some copper. This is recovered by heating the sludge with copper oxide and some of the electrolyte from the cell and eventually concentrating to the point of crystallisation. After copper sulphate has separated the mother liquor is poured off and discarded, the copper sulphate is extracted with water and used in the electrolysis.
—J. F. S.

[Tin;] Primary and secondary recrystallisation [of ——]. G. Masing. Wiss. Veröffentl. Siemens-Konzern, 1922, **1**, [3], 31—34.

In the case of tin, the author shows experimentally that the secondary crystallisation following a secondary deformation is characteristic of that deformation and does not take place if the metal, after casting, is subjected to a similar deformation without being subjected to a primary deformation (*cf.* J., 1922, 256 A). Thus, a sheet of tin which after being cast, was pierced, and then subjected to recrystallisation showed a ring of comparatively small crystals around the hole, whereas a similar sheet that had been rolled before piercing, showed, after recrystallisation at the same temperature, extremely large secondary crystals spread evenly around the hole and gradually merging into the original primary crystals.—A. R. P.

Calcium amalgam; Electrolytic preparation of ——. B. S. Neuhausen. J. Amer. Chem. Soc., 1922, **44**, 1445—1447.

Calcium amalgam is best prepared by electrolysing a 1·75 *N* solution of calcium chloride in a crystallising dish (25 cm. diam.) between a thin layer of mercury which just covers the bottom of the dish and serves as cathode and a platinum plate (2×4 cm.) placed parallel to the surface of the mercury and at a distance of 4 cm. A current of 3·5 amps. at 4—6 volts is passed for 30 mins. This arrangement prevents heating, foaming, and the formation of a black deposit. The amalgam is washed by pouring into 2 litres of distilled water in a fine stream and stored in a bottle filled with carbon dioxide. It contains 0·069—0·075% Ca.
—J. F. S.

Corrosion of metals by water in a closed system; Prevention of ——. P. West. J. Ind. Eng. Chem., 1922, **14**, 601—607.

Metals rust to an appreciable degree only when in contact with both water and free oxygen. Where water is confined in a closed system the dissolved oxygen in it is the principal cause of corrosion. The removal of this will practically stop corrosion in most cases and materially reduce it in others. Free carbon dioxide promotes corrosion in the presence of oxygen but is practically inactive in its absence, except at extremely high temperatures. Other acids, such as nitric, hydrochloric or sulphuric acid, also, when present in a highly diluted condition, have little corrosive action except in the presence of dissolved oxygen. Calcium and magnesium carbonates may retard corrosion by depositing a protective coating on the metal. At very high temperatures these carbonates may give off carbon dioxide or give rise to alkaline solutions, thereby promoting corrosion, especially in the presence of free oxygen. Some chlorides, especially magnesium chloride, are hydrolysed with formation of free acids, which are highly corrosive in the presence of free oxygen, but not otherwise except in high concentration. Carbonates and chlorides are both scale-forming and therefore provide some protection against their own corrosive action. This, however, does not prevent pitting. Sulphates and nitrates are rather scale-forming than corrosive. Commercial processes for the elimination of dissolved oxygen depend on two principles. In the de-oxidising method the hot water is brought into contact with thin sheets of specially prepared metal in a de-activating tank. The water exerts its corrosive activity on the cheap and easily replaced metal rather than on the piping system. In the de-aerating process the water is sprayed over baffles in a de-activator and the free dissolved gases are removed by heating, by vacuum, or by a combination of the two. The latter process removes nitrogen, carbon dioxide, etc., as well as oxygen. By the use of gas-free water the scoring of engines, turbines, etc. is prevented as a result of elimination of the "dirt" due to corrosion. It also increases condenser efficiency 20—25% by eliminating the air blanket round the tubes. The prevention of corrosion by the removal of dissolved oxygen applies to brass as well as to iron and steel. The plant used for these processes is illustrated by diagrams.—H. C. R.

Tellurium poisoning. Adolphi. *See* XIXb.

Patents.

Case-hardening iron and steel; Composition for —— and method of and apparatus for manufacturing such composition or the like. T. A. Goskar and H. B. Hitch. E.P. 182,527, 24.3.21.

Peat in a moist condition is reduced to a homogeneous mass by grinding or pugging and formed into granules, which are dried and carbonised. The peat may be pulped in a pug-mill or in a "Werner-Pfleiderer" mixer, and powdered leather, wood, or barium carbonate may be incorporated at this stage. A convenient method of granulating the plastic mass is to force it through a die-plate and cut off the extruded material in short lengths. —C. A. K.

Iron and steel; Method of producing ——. W. E. F. Bradley. U.S.P. 1,422,733, 11.7.22. Appl., 17.7.18.

A MIXTURE of finely powdered ore and flux is passed through a rotary drum furnace into an electric furnace and a current of a reducing gas is passed through the two furnaces in the opposite direction. —C. A. K.

Carbonising method [*for ferrous metals*]. W. Bonsor, Assr. to W. C. Steenburg. U.S.P. 1,422,530, 11.7.22. Appl., 6.3.22.

"HUMUS soil" containing less than 15% of moisture, and when dried, more than 30% of carbon, more than 3% of nitrogen, and not less than 4·4% of lime, is used as a carbonising agent for ferrous metals.—C. A. K.

Annealing malleable cast iron; Process of ——. C. T. Holcroft. U.S.P. 1,422,710, 11.7.22. Appl., 20.1.21.

THE metal is heated at a rate proportional to its thermal conductivity to a predetermined point of reaction, maintained at that temperature for a predetermined time, and then cooled to a point where sudden cooling will no longer injuriously affect it.—B. M. V.

[*Metal*] *tools and the like; Manufacture of very hard, but ductile* —— *adapted to resist mechanical stresses.* H. Lohmann. E.P. 157,769, 10.1.21. Conv., 7.12.18.

METAL, such as tungsten, titanium, molybdenum, chromium, or iron, is cast, then, in order to break up its coarsely crystalline structure, thoroughly worked by intensive rolling, hammering, forging, or pressing, until a fibrous structure is obtained; it is then case-hardened by any suitable method. —A. R. P.

Electric induction furnaces [*for melting and refining steel, etc.*]. O. Frick. E.P. 174,084, 14.1.22. Conv., 15.1.21.

THE effect of corrosion of the walls of the melting channel in electric induction furnaces having a ring-shaped hearth is reduced by inclining the inner side wall of the channel at a smaller angle to the horizontal than the angle of repose of magnesite, so that this repairing material can be applied to and sintered on corroded parts of the wall during working.—J. S. G. T.

Smelting furnace; Vertical ——. F. Fiechtl. U.S.P. 1,422,684, 11.7.22. Appl., 28.1.21.

VERTICAL retorts extend through a furnace chamber and are provided at both ends with removable covers, the lower covers being operated mechanically. Arrangements are made to introduce air under pressure into the furnace around the retorts. —C. A. K.

Magnetic separator. S. Percival. From L. B. Woodworth, S. T. Tregaskis, The Central Mining and Investment Corp. Ltd., and The Transvaal Consolidated Land and Exploration Co., Ltd. E.P. 182,539, 31.3.21.

IN a magnetic separator of the Wetherill type, having one or two pairs of poles, an auxiliary pole is provided attached to one of the main poles but, preferably, having its own energising coil and means for independent adjustment. Tapping devices are located between the sets of poles to cause rearrangement of the particles of ore before the latter passes between the next set of magnets. —A. R. P.

Tungsten alloys; Methods of manufacturing bodies of —— [*e.g., filaments for incandescence electric lamps, discharge tubes, etc.*]. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 182,699, 19.7.21.

A TUNGSTEN body of desired shape, *e.g.*, filament, wire, sheet, etc., is heated to 1000°—1300° C. in a protective atmosphere and coated with the alloying metal, *e.g.*, iron, electrolytically or otherwise. Excess of electrolyte is removed and the composite body heated to at least 1600° C., whereby a homogeneous alloy is produced.—J. S. G. T.

Alloy for medical and dental purposes. Metallwerk M. Brose und Co. G.P. 352,028, 19.10.20.

AN alloy which is chemically resistant and is easily worked consists of 75 pts. of copper, 9 pts. of nickel, 10 pts. of silver, and 6 pts. of aluminium.—A. G.

Gases; Process of discharging smelter —— [*into the atmosphere*]. W. H. Howard, Assr. to American Smelting and Refining Co. U.S.P. 1,422,575, 11.7.22. Appl., 8.3.21.

FURNACE gases which are obnoxious or harmful to vegetation or animal life are discharged into a high chimney simultaneously with an unobjectionable gas having a temperature higher than that of the atmosphere. The second gas is added in such a manner that it mixes thoroughly with the obnoxious gases, and in such volume that the mixture formed readily diffuses into the atmosphere, whereby before the mixture comes in contact with the vegetation in the neighbourhood the objectionable properties are reduced owing to the extreme dilution of the obnoxious gases.—L. A. C.

Metallurgical process. W. E. F. Bradley. U.S.P. 1,422,734, 11.7.22. Appl., 4.9.18. Renewed 5.12.21.

IN a process in which ores are reduced by means of a hydrocarbon gas, a metallic oxide and free carbon are added to the molten reduced charge.—C. A. K.

Electrotinning [*; Electrolyte for* ——]. L. Schulte. U.S.P. 1,423,686, 25.7.22. Appl., 12.7.20.

DILUTE hydrofluoric acid is added to an aqueous solution of caustic potash until an acid reaction is obtained, the solution is further diluted and metallic tin dissolved in it with the aid of an electric current.—B. M. V.

Electroplating process. N. V. Park. U.S.P. 1,423,815, 25.7.22. Appl., 6.7.21.

BY means of a nozzle with openings of various diameters air currents of different pressures are directed downwards into an electrolytic cell provided with anode and cathode elements. The air currents agitate the electrolyte and effect a continuous washing of metal from the anode for transfer to the cathode.—H. H.

Iron and manganese oxides; Treatment of ores containing ——, *or sludges containing such ores.* O. Johl. G.P. 349,067, 10.7.20.

THE finely divided particles of iron and manganese oxides in sludges containing the same are caused to coagulate into large particles, capable of being easily separated, by the addition of salts of aliphatic or aromatic acid esters, such as salts of amyl- or ethyl-sulphonic acids, or of benzene-, naphthalene-, or terpene-sulphonic acids, with or without the addition of saturated or unsaturated fatty acids, fatty sulphonic acids, picric acid, sulphanilic acid, or the like, or salts of these acids. —L. A. C.

Metals; Separation of —— *from their solutions.* H. Bardt. G.P. 352,783, 22.1.20.

SOLUTIONS of metallic salts are treated with sub-

stances containing polysaccharides, especially sawdust, under pressure at a high temperature.
—A. B. S.

Metals; Process for precipitating —— from solutions. H. Bardt, Assr. to Soc. Hidro-Metalurgica. U.S.P. 1,423,070, 18.7.22. Appl., 17.9.21.

See G.P. 352,783 of 1920; preceding.

Reducing aluminium oxide. E.P. 182,609. *See* VII.

XI.—ELECTRO-CHEMISTRY.

Electrochemistry of non-aqueous solutions. I. Measurement of current density and potential difference in the electrolysis of metallic salts in pyridine. R. Müller. Monatsh., 1922, **43**, 67—74.

A form of electrolytic cell suitable for the measurements in question has been devised, and the preparation of an appropriate standard electrode investigated. The element, Ag/*N*/10 $AgNO_3$ in pyridine, has a potential (measured with reference to the calomel electrode) of +0·28 volt (hydrogen = 0), and the element, Ag/*N*/10 $AgNO_3$ in pyridine /NH_4NO_3 saturated solution in pyridine, has +0·26 volt (hydrogen = 0).—C. K. I.

Electrochemistry of non-aqueous solutions. II. Decomposition potential and electrode potentials of silver nitrate in pyridine and the potential of silver in these solutions. R. Müller and A. Duschek. Monatsh., 1922, **43**, 75—80. (*Cf. supra.*)

The decomposition potentials are: *N*/10, $AgNO_3$, 2·15 volts; *N*/1 $AgNO_3$, 2·05 volts; saturated $AgNO_3$ solution, 1·95 volts; and the silver potentials (invariant with current density) are: Ag/*N*/10 $AgNO_3$, +0·24 volt; Ag/*N*/1 $AgNO_3$, +0·33 volt; Ag/saturated $AgNO_3$ solution, +0·33 volt (hydrogen = 0). The anodic potential differences are functions of the current density.—C. K. I.

Electrolytic dissociation; Relation between adsorption and ——. M. A. Rakusin. Biochem. Zeits., 1922, **130**, 282—285.

When a porous pot is immersed in solutions of sucrose or common salt, the concentration of the solution increases owing to adsorption of water (so-called negative adsorption). The author ascribes this to the adsorption of colloids and the non-adsorption of electrolytes.—H. K.

Electrolysis of sodium silicate solutions. Spencer and Proud. *See* VII.

Actinometer. Athanasiu. *See* XXI.

Patents.

Storage batteries; [Electrolyte for] dry ——. W. Gardiner. E.P. 182,865, 15.3.21.

A mixture of powdered glass with five parts of an acid solution, *e.g.*, sulphuric acid, and one part of a soluble silicate, *e.g.*, sodium silicate, is poured into the battery and allowed to set. Alternatively, the mixture may be allowed to set prior to being introduced into the battery, and is then added in powdered form, and liquid electrolyte added to fill up interstices. A layer of absorbent paper, *e.g.*, Swedish filter paper, is placed on top of the electrolyte and is covered with a perforated rubber plate.
—J. S. G. T.

Insulating and resistant articles and products thereof; Method of manufacturing ——. F. T. Lahey. U.S.P. 1,422,720, 11.7.22. Appl., 11.3.21.

Vegetable fibre is treated with a dilute alkali solution, a vulcanisable oil, and rubber at a temperature such that the fibrous structure is not destroyed. A vulcanising agent is added, and the mixture heated so that oil is precipitated within the structure of the fibre and the material is vulcanised.—J. S. G. T.

Solutions; Electrolysis of —— and apparatus therefor. Hooker Electrochemical Co., Assees. of A. H. Hooker. E.P. 167,469, 22.7.21. Conv., 5.8.20.

See U.S.P. 1,388,466 of 1921; J., 1921, 740 A.

XII.—FATS; OILS; WAXES.

Olive oil; Extraction of —— from olives. H. Mastbaum. Chem.-Zeit., 1922, **46**, 669—672.

Current methods of oil-pressing in Spain are described. They are for the most part very crude and the oil is the only part of the olives which is utilised. As a result of considerable experimental work, J. M. Luque (Primer Congreso Nacional de Ingenieria (Madrid), 1919, Tomo III., p. 21) has suggested the following improvements in the industry. The olive pressing should be concentrated in large factories. The olives should be ground when fully ripe, but as fresh as possible. The kernels should be broken but not pulverised. Rolls would be more suitable for this purpose than the edge-runners used at present. The mixing of the olease of the seed with the oil would thus be reduced and the shells of the kernels would be left in the form of fragments of sufficient size to permit of easy separation from the pulp. Only one pressing is advocated, and that cold. The pulp should be dried and extracted with a solvent as soon as possible. If storage of the pulp is necessary, sulphur dioxide may be used as a preservative. The extracted oil will then be low in free fatty acids and easy to refine, and an edible oil can be obtained from it. The stearine separated from it can be used for soap-making. The extracted pulp should be dried and freed from the shells of the kernels. The aqueous fluid is concentrated, and may be mixed with the dry pulp and other ground vegetable matter to form feeding stuffs, or it may be treated for the recovery of potash by calcination, or used as a binding material for making briquettes. The shells of the kernels give a better yield of tar, wood spirit, and acetic acid than the best hard woods. The high potassium content of all parts of the olive tree points to the need for a large application of potash fertilisers in its cultivation.
—H. C. R.

Arachis oil; Chemical constitution of ——. A. Heiduschka and S. Felser. Z. Unters. Nahr. Genussm., 1922, **43**, 381—382.

The differences in the proportions of the various fatty acids contained in two samples of arachis oil of Spanish and Virginian origin respectively, examined by Jamieson and his collaborators (J., 1921, 740 A) are as great as the corresponding differences between either of them and the commercial oil examined by the authors (J., 1920, 272 A). Considerable differences occur in the per-

centages of saturated and unsaturated acids and also in the percentage of linolic acid in the latter fraction. The constitution of the saturated acids seems, however, to be fairly constant.
—H. O. R.

Fats (glycerides); Synthesis of ——. C. Amberger and K. Bromig. Biochem. Zeits., 1922, **130**, 252—266.

The use of high temperatures is inadmissible for the preparation of mixed glycerides of known constitution. The authors have applied Fischer's methods (J., 1920, 790 a). α-Stearo-βγ-dipalmitin, m.p. 63·5° C., occurs in goose fat and was prepared from α-monostearin and palmitic acid chloride. β-Stearo-αγ-dipalmitin, m.p. 59·1° C., was prepared from αγ-dipalmitin, m.p. 69·5° C. The latter was prepared from βγ-dipalmitin-α-iodohydrin, m.p. 46·2° C. by the action of silver nitrite. α-Palmito-βγ-distearin, m.p. 63·2° C., was prepared from α-monopalmitin and stearyl chloride. The isomeride, β-palmito-αγ-distearin, m.p. 67·9° C., was prepared from αγ-distearin. α-Palmito-βγ-diolein, prepared from α-palmitin and oleic acid chloride, was an oil. From α-olein, a pale yellow oil, α-oleo-βγ-distearin, m.p. 42° C., was prepared.—H. K.

Lipase; Influence of various antiseptics on the activity of ——. L. S. Palmer. J. Amer. Chem. Soc., 1922, **44**, 1527—1538.

Data are presented on the influence of various concentrations of several antiseptics on the hydrolysis of emulsions of milk fat in gum acacia solutions, using commercial steapsin as the source of lipase. Formaldehyde up to concentrations of 1 pt. in 250 had no detrimental effect on the activity of the lipase, 1% solutions being required to produce a retardation of the enzyme action. Chloroform in concentrations from 1·5 to 2·5% retarded the lipase activity 20—60%. Acetone in concentrations of 6% and 12% retarded the lipolysis 12—25%. A freshly prepared 3% solution of iodoform in acetone added so as to give a concentration of 0·3% retarded the lipase activity 25—40%. When using a similar solution of iodoform which had stood for some time, practically complete inhibition was obtained with this and even smaller concentrations of iodoform. Iodoform alone retarded lipolysis in direct proportion to the concentration of the antiseptic present, the effect varying from a 15% retardation with 0·03% concentration of iodoform to a 55% retardation with 0·5% concentration of antiseptic. Old solutions of iodoform in acetone contain free iodine, which has a marked effect on lipase activity. Iodine in concentrations of 0·045% or more inhibited lipolysis entirely. Results similar to those with iodine were obtained by the use of bromine water. Higher concentrations of bromine were found necessary to inhibit the lipase completely, however, a concentration of 0·25% retarding the enzyme activity only 93—94%. Mercuric chloride inhibited lipase activity completely in 0·1, 0·2 and 0·3% concentration. Chloral hydrate not only retarded the lipase action, but also failed as a germicide when using cow's milk as substrate. (*Cf.* J.C.S., Sept.)—H. W.

Catalytic addition of hydrogen. Influence of oxygen on the catalyst. W. Normann. Ber., 1922, **55**, 2193—2197.

Working under conditions which are considered to exclude the presence of oxygen and with hydrogen which is free from any trace of the latter, the hardening of cottonseed oil has been effected in the presence of reduced nickel (from the cyanide or chloride), nickel powder, or palladised kieselguhr. It appears therefore that Willstätter's assumption of the necessity for the presence of oxygen is unjustified.—H. W.

Acid value of fatty acids and fats; Electrometric determination of the ——. R. Kremann and F. Schöpfer. Seife, 1922, **7**, 612—614, 656—659. Chem. Zentr., 1922, **93**, II., 1246—1247, IV., 72—73. (*Cf.* J., 1921, 896 a.)

The electrometric titration of fats and fatty acids in alcoholic solution is possible, but in the case of palmitic acid the titration curve is not of a form agreeing with theoretical considerations, and in the titration of caprylic and capric acids it is impossible to obtain a titration curve owing to the contamination of the platinum electrode surfaces with precipitated soap. Mechanical cleaning of the electrodes appears to be impossible owing to the damage to the platinised surfaces caused thereby. The platinised hydrogen electrodes were therefore replaced by smooth ones, which were arranged half in air and half in the liquid to be titrated, and by this means it was possible to titrate fatty acids. The liquid was titrated with $N/10$ alcoholic alkali at room temperature. The results were as satisfactory as those obtained using phenolphthalein as indicator or by conductivity measurements, and the method has a greater range of application than the latter method. The use of $N/10$ aqueous solutions for the electrometric titration is preferable to that of alcoholic solutions in special cases, such as that of sunflower seed oil, and is useful as a secondary method in cases where with the use of alcoholic solutions the bend in the potential-volume curve is not sufficiently well marked. Titrations with $N/2$ aqueous solutions are not to be recommended in consequence of the more marked disturbance due to the separation of soap, which interferes with the equilibrium of the solution. The chief condition for obtaining satisfactory potential curves is to wait for a steady potential to be reached after each addition of alkali. Disturbances due to the separation of soap on the electrode can be overcome by scraping the smooth electrodes.—H. C. R.

Θι-Decylenic acid; Synthesis of ——. A. Grün and T. Wirth. Ber., 1922, **55**, 2206—2218.

Ethyl undecylenate is reduced by sodium and ethyl alcohol to undecenol, $CH_2:CH.[CH_2]_8.CH_2OH$, b.p. 250° C. at atmospheric pressure, 122° C. at 3 mm., m.p. $-7°$ C., which is converted by chlorosulphonic acid in dry ethereal solution into undecenyl hydrogen sulphate. The ester (or the corresponding acetate) is oxidised by chromic acid or preferably by permanganate to ι-hydroxycapric acid, $CH_2(OH).[CH_2]_8.CO_2H$, m.p. 75° C. The methyl ester of the latter is converted by stearyl chloride into methyl-stearoxycaprate, m.p. 43° C., which decomposes readily when distilled under atmospheric pressure into stearic acid and methyl Θι-decylenate; the latter is hydrolysed to Θι-decylenic acid, b.p. 143° C. at 6 mm., identical with the acid obtained from butter fat (see page 680 a). Alternatively, ι-hydroxycapric acid is prepared by the reduction of potassium ethyl sebacat in ethyl alcoholic suspension by sodium. Th iodine and acid values of Θι-decylenic acid sinl gradually when the substance is preserved, prob ably owing to the formation of a lactone. Deca lactone, b.p. 153° C. at 15 mm., prepared by th action of sulphuric acid (80%) on the acid at 90° C is saturated and neutral; it is converted by hydro lysis into a hydroxy acid, m.p. 44° C. The com pounds are regarded provisionally as γ-decalacton and γ-hydroxydecoic acid. (*Cf.* J.C.S., Sept.)

Patents.

Decolorising power of silicates for fatty and mineral oils, etc.; Process for increasing the ——. Pfirschinger Mineralwerke Gebr. Wildhagen und Falk. G.P. 339,919, 21.11.19.

Natural silicates, such as clay and kaolin, are decomposed, for example, with hydrochloric acid of the required concentration, so that they are wholly or partially converted into hydrated silicic acid. —H. C. R.

Sulphonic acids from petroleum; Purification of ——. Oelwerke Stern-Sonneborn A.-G. G.P. 350,299, 26.2.15.

The crude acids, separated from their salts, are washed with dilute mineral acids, *e.g.*, with 40—50% sulphuric acid at about 60° C. The practically ash-free sulphonic acids thus obtained are specially suitable for the hydrolysis of fats; products containing salts of the acids hydrolyse fats only incompletely and slowly, and the ash content of the glycerol produced is undesirably high.—A. G.

Oils and fats; Process for retarding occurrence of rancidity in ——. Gebr. Schubert Chem. Fabr. G.P. 351,566, 4.1.19.

Silica or silicates are added to the oil or fat, and if necessary it is treated with an indifferent gas, *e.g.*, nitrogen.—A. G.

Catalyst; Production of a —— for the hydrogenation of unsaturated organic compounds. C. und G. Müller, Speisefettfabr. A.-G. G.P. 352,431, 27.3.18.

Nickel salts of boric acid are precipitated on an inert base, *e.g.*, kieselguhr, and are then heated in hydrogen. The catalyst is insensitive to the action of air.—A. G.

Alcohols; Process for the production of wax-like —— from wool-fat. W. Schrauth. G.P. 353,048, 26.9.15.

Wool-fat is hydrogenated, the product is saponified, and the soap is treated with an extraction medium, insoluble in water, *e.g.*, carbon tetrachloride, benzene, benzine, etc.—A. G.

Catalysts for hydrogenation. G.P. 352,439. *See* XX.

Scammony resin. Deane and Edmonton. *See* XX.

Patents.

Lead chromate pigments; Manufacture of ——. H. Hetherington and W. A. Allsebrook. E.P. 182,693, 13.7.21.

Lead sulphate paste, *e.g.*, 606 pts. by weight of freshly precipitated, well-washed 50% paste, is agitated and a solution of a normal alkali or ammonium chromate, *e.g.*, a 10% solution of sodium chromate, is slowly added to the mass at such a rate that a clear liquor is obtained before any further addition of the solution is made. If 1 mol. of sodium chromate is added per mol. of lead sulphate a deep yellow pigment is obtained, and by reducing the quantity of sodium chromate a paler product of any desired shade can be produced. The product is washed until free from sodium sulphate, and is then pressed and dried.—L. A. C.

Resins and oil-soluble dyestuffs; Manufacture of novel ——. H. Plauson and J. A. Vielle. E.P. 182,497, 7.1.21.

Coloured, oil-soluble "azo resins" are prepared by incorporating a diazo compound with a phenol-formaldehyde or ketone-formaldehyde condensation product, preferably before condensation is complete. For example, 94 pts. of phenol is melted with 7½ pts. of hexamethylenetetramine, and 15 pts. of diazotised *p*-nitraniline is added to the product, with agitation. On cooling, a solid metallic-green or orange coloured azo resin is obtained, which dissolves in oils and fats to form an orange-coloured solution.—L. A. C.

Vapours and gases formed by heating fatty oils, gums, resins and other organic materials; Processes and apparatus for treating the ——. P. W. Webster. E.P. 182,869, 30.3.21.

Air is admitted in regulated quantity to the vessel containing the material during the production of the fumes, and the fumes evolved are collected by surface condensation, scrubbing with water, and treating the uncondensed fumes with an alkaline solution. The apparatus comprises a receptacle having a means for controlling the amount of air admitted, to which is connected a fume condenser, a water scrubbing device, and a chemical treatment apparatus, connected together in series, together with a means for positively passing fumes through the apparatus. The receptacle can be quickly and easily disconnected from the fume-collecting apparatus by removing the lid, which is connected with the fume-collecting apparatus by a flue having a telescopic and a swivel joint. To prevent flame passing through the apparatus a container having fine mesh screens in it is provided.—H. C. R.

Condensation products from phenol and formaldehyde; Process for the manufacture of insoluble ——. F. B. Dehn. From S. Satow. E.P. 182,886, 6.4.21.

Products which can be manufactured without the use of high pressure, and possessing properties which render them capable of being turned, sawn, and polished, are prepared by the addition of organic compounds containing the CH_2OH or CHOH group, for instance, hydroxy-fatty acids such as glycollic acid, lactic acid, and malic acid, or alcohols such as glycerin, butyl alcohol, and cholesterol, or hexoses and the like, to the oily product obtained by reaction between equimolecular weights of phenol and formaldehyde. The products may be heated for several hours at 90°—130° C., or may be diluted with alcohol, acetone or the like, and the solutions used for impregnating paper or other porous material. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 27,096 of 1908, 129,993, and 148,264; J., 1909, 843.)—L. A. C.

Condensation product from naphthalene and glycollic acid; Method for the production of a ——. Elektrochem. Werke G.m.b.H., H. Bosshard, and D. Strauss. E.P. 171,956, 10.1.21. Conv., 4.7.19.

A mixture of 129 pts. of naphthalene, 40 pts. of glycollic acid (or 30 pts. of glycolide), and 10 pts. of phosphorus pentoxide, is heated under pressure for about 15 hrs. at 130°—170° C. with agitation. Carbon dioxide is allowed to escape from the apparatus from time to time. The product, after separation of unchanged naphthalene by steam distillation, is a yellow resin resembling shellac and fusing at 80°—85° C.—L. A. C.

Resin; Polyglycerol ——. L. Weisberg and R. S. Potter, Assrs. to The Barrett Co. U.S.P. 1,424,137, 25.7.22. Appl., 19.2.21.

A mixture of a polyglycerol and a polybasic aromatic acid is heated until a water-resisting product is obtained.—L. A. C.

Paint. A. C. Holzapfel. U.S.P. 1,422,711, 11.7.22. Appl., 2.3.22.

Paints containing residual pitch derived from oils and fats are deodorised by addition of 1—5% of acetone.—B. M. V.

Invisible ink. C. F. Morse, Assr. to The Invisible Process Co. U.S.P. 1,423,246, 18.7.22. Appl., 14.11.21.

An invisible ink is composed of a solution containing basic ferric sulphate, mixed with 25—75% of its weight of phosphoric acid.—L. A. C.

Resins, especially artificial resins; Solvents for ——. W. Schrauth. G.P. 351,688, 25.3.19. Addn. to 349,905 (J., 1922, 425 A).

Cyclohexanol esters and homologues of the same, either alone or mixed with other solvents, are used as solvents for resins instead of cyclohexanol as described in the chief patent.—L. A. C.

Wood; Process for facilitating the cleavage of ——, particularly for lead pencil manufacture. E. Beutel and K. Suchy. G.P. 349,813, 20.3.19. Conv., 1.3.19.

The wood is treated with alkalis or mineral acids, and if necessary with the addition of compounds easily dissociated, *e.g.*, ammonium compounds, in a pressure vessel at a temperature of about 200° C. Ammonium salts may also be used alone. The treated wood is subjected to the usual paraffin bath, using oils boiling above 200° C., such as paraffin, linseed oil, stearic acid, etc., dyestuffs soluble in the oil being added as required.—A. G.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Patents.

Latex; Products obtained from rubber-containing ——. E. Hopkinson. E.P. 157,975, 11.1.21. Conv., 16.1.20.

Rubber products in increased yield and having a tensile strength about 20% higher than those obtained by the usual methods, are obtained by agitating rubber-containing latex with a preservative material to prevent coagulation, and delivering the mixture through an atomiser into a chamber in which it is dried by contact with a stream of air or other gases heated to about 200° F. (93° C.). Coagulation is prevented by the addition of 0·1% of ammonia if the latex is treated alone, or by the addition of 0·1% of saponin, or other substances, such as glue or glycerin, if vulcanising agents or compounding ingredients are mixed with the latex before treatment. The dried product is deposited by passing the gases carrying it through a winding channel and spiral collectors, and the spongy product obtained thereby is formed into a compact mass by compression in a hydraulic press or between rollers.—L. A. C.

Sponge rubber; Manufacture of ——. A. J. Ostberg and A. Kenny, Assrs. to The Standard Rubber Works Proprietary, Ltd. U.S.P. 1,422,884, 18.7.22. Appl., 18.8.20.

See E.P. 172,398 of 1920; J., 1922, 67 A.

Insulating products. U.S.P. 1,422,720. *See* XI.

XV.—LEATHER; BONE; HORN; GLUE.

Patents.

Skins and hides; Mixture for depilating ——. W. Ulke. G.P. 348,413, 31.12.20.

Dextrin is added to a depilating mixture containing alkali or alkaline-earth sulphides and covering material, a suitable mixture containing, *e.g.*, strontium sulphide, maize starch powder, talc, dextrin, essential oils, and "nerolin." The dextrin protects the skin and hair papillæ from the action of the sulphide, and also prevents liberation of hydrogen sulphide.—L. A. C.

Millboard. E.P. 182,884. *See* V.

XVI.—SOILS; FERTILISERS.

Plant indicators of soil types. A. P. Kelley. Soil Sci., 1922, 13, 411—424.

The acidity of a number of soils was determined by colorimetric methods and the characteristic flora examined, with a view to correlate particular plants with definite ranges of soil acidity. A number of plants were found to be indicative of definite degrees of acidity. The acidity of any soil type is influenced by such factors as arrested leaf decay, physiographical features and degree of slope, elevation, and season. Variation in some species of plants may be induced by changes in soil acidity. The carbon dioxide in the soil solutions did not affect p_H values determined by the colorimetric method.—A. G. P.

Acid soil studies. III. Influence of calcium carbonate, calcium oxide, and calcium sulphate on the soluble soil nutrients of acid soils. R. H. Robinson and D. E. Bullis. Soil Sci., 1922, 13, 449—460.

Five acid soils were treated with varying quantities of the carbonate, oxide, and sulphate of calcium, and stored with a maintained optimum water content. Periodical analyses were made of the soluble salts obtained by a 1:5 water extraction. The amounts of calcium added were sufficient to satisfy the lime-requirement determined by the Veitch method. In field trials the soils showed widely different results on treatment with limestone. The chief difference brought out by analysis of the water extracts of the limed soils, was the rapid production of nitrates in those soils which had responded to lime in the field. The content of water-soluble phosphates and sulphates was not appreciably altered by any of the treatments. The soluble potash and magnesium in all soils was increased by treatment with calcium sulphate. In pot experiments, addition of monocalcium phosphate, with or without lime, increased the nitrate production of those soils which did not respond to lime alone; but field trials did not confirm this. —A. G. P.

Soil acidity; Effects of lime, leaching, form of phosphate and nitrogen salt on plant and —— and the relation of these to the feeding power of the plant. F. C. Bauer and A. R. C. Haas. Soil Sci., 1922, 13, 461—480.

The actual acidity of plant juices usually varied with that of the nutrient medium and was in most cases closely related to the growth and feeding power of the plant. Liming reduced, and leaching increased the acidity of both nutrient medium and plant juices. Acid phosphate (superphosphate) increased the acidity more than rock phosphates. Increased soil acidity improved the availability of rock phosphates. Ammonium nitrate produced greater acidity in the soil and juices of maize tops than did sodium nitrate. (*Cf.* J.C.S., Sept.) —A. G. P.

Soils; Further studies on the soluble salt content of field ——. C. E. Millar. Soil Sci., 1922, 13, 433—448.

The soluble salt content of a number of soils was determined at various depths and seasons by the freezing point method. In uncropped soils the soluble salt content of the top 6 in. was low in early spring and late autumn, but rose during the summer. In samples from depths of 6—12 ins. the salt content was low and showed no tendency to reach a maximum in summer. Soluble salts tended to accumulate in the surface ¼ in. of uncropped soils, particularly in dry seasons, but the growth of plants to a large extent prevented this, and also influenced the amount of soluble salts in the samples from a depth of ¼—6 ins. Rainfall is an important factor in the distribution of soluble salts in soils. The hoeing in of organic matter did not affect the rate of solution of virgin soils.—A. G. P.

Azoification in soil; Influence of salts on ——. J. E. Greaves, E. G. Carter, and Y. Lund. Soil Sci., 1922, 13, 481—499.

The effects of salts of sodium, potassium, calcium, magnesium, manganese, and iron on nitrogen fixation in soils are recorded. The toxicity of the individual salts is specific and is not governed by the negative ion. The salts examined have a less toxic action on nitrogen-fixing bacteria than on ammonifying or nitrifying bacteria. (*Cf.* J.C.S., Sept.)—A. G. P.

Displaceable potash in soils; Significance of —— *in plant nutrition.* A. von Nostitz. J. Landw., 1922, 70, 45—72.

Soils, packed in tubes, were leached with 5% ammonium nitrate solution and the extracts examined for other bases. Calcium, magnesium, potassium, and sodium appeared in considerable quantities, and the rate of extraction by successive amounts of ammonium nitrate solution was in the order named. In no case could the total amount of a base present in the soil be removed by this process. A similar basic exchange was shown to occur with mica and felspar. Comparison was made in pot experiments between plants grown in the original soil and in that leached with ammonium nitrate solution, to which was added respectively the amounts of calcium and magnesium, or of calcium, magnesium, and potassium removed by the leaching. Suitable adjustments were made for the increased nitrogen-content of the leached soil. Plants grown in the leached soil with addition of calcium, magnesium, and potassium were only slightly inferior to those in the original soil, but those grown in leached soil with addition of only calcium and magnesium showed every sign of potash-starvation. A second crop on the same soils gave similar results. The germination of seeds in the soil lacking potash was slow and the growth of plants poor from the first. Sand cultures showed that germination of seeds increased with the proportion of potash in the culture solution, as also did the rate of growth of the seedlings, but the optimum potash content depended on the amounts of calcium and magnesium present. In estimating the fertiliser requirements of soils the amount of potash which can be liberated by a process of base-interchange should be taken into consideration.
—A. G. P.

Manganese in plants; Rôle of ——. J. S. McHargue. J. Amer. Chem. Soc., 1922, 44, 1592—1598.

Radish, Alaska garden pea, Canada field pea, cowpeas, lettuce, tomatoes, spinach, carrots, onions, garden beans, cabbage, wheat, oats, clover, and velvet beans when grown in a medium which contained no manganese made a normal growth for 6—8 weeks, but thereafter developed a chlorotic condition and failed to make further growth of any consequence. The normal condition of the plants during the first few weeks of growth is accounted for by assuming that the manganese which the seed contains is sufficient to maintain a normal metabolic process during this part of the plant's growth and that the chlorotic condition is a result of the lack of a further supply of available manganese. Non-leguminous plants appear to be less sensitive than legumes to lack of manganese, thus suggesting that manganese is concerned in nitrogen assimilation and the synthesis of proteins. Apparently manganese plays the rôle of a necessary catalyst in plant metabolism and together with iron functions in the synthesis of chlorophyll.
—H. W.

Superphosphates; Analysis of ——. C. Tibaldi. Giorn. Chim. Ind. Appl., 1922, 4, 303.

The official (Italian) method of estimating the proportion of phosphoric anhydride soluble in water and in ammonium citrate solution may be shortened by omitting the digestion with water. Five grams of the material is ground three times with water, in a basin, transferred to a 500 c.c. flask, digested for 1 hr. with 100 c.c. of ammonium citrate solution at 45°—50° C., and made up to volume, 100 c.c. being taken for the precipitation in the ordinary way.—T. H. P.

Calcium in natural phosphates. Meurice. *See* VII.

XVII.—SUGARS; STARCHES; GUMS.

Acetol. I. A new test for carbohydrates. O. Baudisch and H. J. Deuel. J. Amer. Chem. Soc., 1922, 44, 1585—1587.

The test depends on the production of acetol from carbohydrates. An aqueous solution of the carbohydrate (0·1 g. in 100 c.c.) is treated with solid sodium bicarbonate (5 g.), and distilled nearly to dryness. With the carbohydrates which are more readily attacked, the solution in the distilling flask very quickly turns brown and the distillate has a sweet odour. The residue in the flask, after distillation, has a strong typical caramel odour. The distillate is treated with *o*-aminobenzaldehyde (30 mg.) and enough potassium hydroxide solution to give a decidedly alkaline reaction; after addition of a piece of porous plate, it is evaporated over a free flame to ⅓ of its volume, cooled, and acidified with hydrochloric acid. Solid sodium bicarbonate is added till the solution is alkaline to litmus. The presence of acetol is shown by a strong bluish fluorescence which can be seen in daylight but more readily in light of short wave length such as that yielded by the iron arc. To confirm the test, the 3-hydroxyquinaldine is extracted by shaking the solution several times with ether free from alcohol; the extract is dried over sodium sulphate and the solvent is removed. The colourless, needle-like crystals of 3-hydroxyquinaldine which remain dissolve readily in a little alcohol, and the fluorescence shows up strongly after addition of water to the alcoholic solution. The sensitiveness of the reaction has not been determined except for dextrose, with which quantities as small as 5 mg. give a positive result. The test is shown by arabinose, xylose, ribose, lyxose, dextrose, lævulose, mannose, galactose, glucosamine, lactose, sucrose, maltose, and dextrin, but not by acetoacetic acid, glycerol, β-hydroxybutyric acid, lactic acid, starch, or glycogen. The formation of 3-hydroxyquinaldine on treatment with o-aminobenzaldehyde and potassium hydroxide appears to be a specific reaction of acetol; it is not given by pure methylglyoxal, aldol, acetone, acetaldehyde, ethyl acetoacetate, crotonaldehyde, or ethyl alcohol.—H. W.

Xylan; Methyl ethers of ——. E. Heuser and W. Ruppel. Ber., 1922, 55, 2084—2088.

Although xylan is very readily soluble in solutions of alkali hydroxides it cannot be converted by methyl sulphate in these media into methylated products containing more than 1—1·5 methoxy groups for each $C_5H_8O_4$ complex. The products thus obtained are freely soluble in cold water, but the solutions become turbid when they are heated owing to the separation of methyloxylan. Better results are obtained with methyl iodide and silver oxide. Xylan, pre-methylated with sodium hydroxide and methyl sulphate, is almost completely methylated by these reagents boiling under slightly increased pressure and is completely converted into dimethylxylan, softening at 65°—70° C., when similarly heated under pressure at 100° C.—H. W.

Wheat starch. Wallis. *See* XIXa.

Patents.

Grape sugar; Manufacture of ——. P. W. Allen, Assr. to Penick and Ford, Ltd. U.S.P. 1,422,328, 11.7.22. Appl., 17.2.19.

In the preparation of glucose from starch, the sugar liquor, freed from protein impurities, is heated to about 145° F. (63° C.) at a density of 42° B. (sp. gr. 1·41), and subjected to a beating operation in the air, thus giving the mass a frothy porous consistency, and is then allowed to stand until crystallised.—A. G. P.

Fermentable sugar from wood. G.P. 351,681 and 352,773. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Yeast cells; Action of saponin-substances on ——. F. Boas. Ber. Deuts. Bot. Ges., 1922, 40, 32—38. Chem. Zentr., 1922, 93, III., 64.

There is a great similarity between the action of saponins on blood corpuscles and that on yeast cells. Digitonin and smilacin are very active, and guaiacum saponin very inactive toward blood corpuscles in the Kobert test. Digitonin and smilacin inhibit fermentation by yeast, whereas other saponins examined accelerate fermentation, in solutions containing little or no dissolved salts, by increasing the permeability of the cell without injury. —A. G. P.

Yeast; Action of mercuric chloride, phenol, and quinine on ——. G. Joachimoglu. Biochem. Zeits., 1922, 130, 239—248.

From measurements of the loss of weight due to carbon dioxide evolved, it is found that the growth of yeast is inhibited by mercuric chloride over the range of dilutions, 1 in 66,000 to 1 in 1,200,000; by quinine hydrochloride between 1 in 360 and 1 in 675, but not at higher dilutions; by phenol at 1 in 1000, but not at 1 in 10,000. The so-called Arndt-Schulz law, that small quantities of a poison act in an opposite sense to large quantities is invalid.—H. K.

Lactic fermentation; Action of acids on the course of ——. E. Bachrach and H. Cardot. Comptes rend. Soc. Biol., 1922, 86, 583—586. Chem. Zentr., 1922, 93, I., 1414.

Initial acidification of the substrate only affects the rate of propagation of the bacillus during the first hour of the fermentation. Initial acidity, produced by hydrochloric, nitric, sulphuric, and acetic acids, had no effect on the amount of acid produced by fermentation. Phosphoric acid alone had an unfavourable effect on fermentation.—A. G. P.

Aspergillus niger; Utilisation of the ternary substances in the growth of ——. E. F. Terroine and R. Wurmser. Comptes rend., 1922, 175, 228—230.

The ratio of the dry weight of the mycelium formed to the weight of the nutrient which disappeared during its growth, was determined under various conditions. The results indicate that the fungus exhibits complete indifference towards the composition or structure of the various sugars (dextrose, lævulose, sucrose, maltose, arabinose, and xylose) used as sources of carbon, development proceeding at about the same rate in all cases. The concentration of the nitrogenous nutrient material had likewise no influence on the ratio of utilisation. The nature of the source of nitrogen had a distinct influence, and two well-defined groups were found, the first, comprising ammonium sulphate, guanidine, urea, ammonium nitrate, and nitric acid, giving a ratio of about 0·42, and the second group, comprising sodium and aluminium nitrates, giving a lower ratio of 0·34—0·35. The energy of synthesis, *i.e.*, the energy required for the development of the mycelium, does not depend on either the composition or structure of the sugar, but it is greater when the nitrogen is presented as nitrates than when ammoniacal nitrogen, urea or nitric acid is the starting point.—G. F. M.

Spent washes from saccharified wood; Detection of unfermented sugar in ——. H. Pringsheim. Cellulosechem., 1922, 3, 77—78.

The presence of unfermented hexoses in the spent washes obtained by the fermentation of liquors from saccharified wood is detected by the difference in solubility of glucosazone and pentosazone in hot water. 25 c.c. of the spent wash is neutralised, faintly acidified with acetic acid, treated with 2 c.c. of 50% acetic acid and then with a 2% solution of potassium permanganate, added slowly from a burette until the supernatant liquid is practically colourless. Two portions of 75 c.c. of the spent wash are then treated exactly alike; they are neutralised, slightly acidified, and treated slowly with the previously ascertained quantity of permanganate in the presence of 3·4 c.c. of 50% acetic acid for every 50 c.c. of permanganate used. After standing all night the manganese dioxide is collected on a small layer of kieselguhr spread on paper on a Buchner funnel, and washed. The filtrates are united and concentrated *in vacuo* at 50° C. to a volume of 50—25 c.c. according to the quantity of sugar. Ten c.c. of this solution is made alkaline with sodium carbonate, filtered, very slightly acidified with acetic acid, and heated in a boiling water-bath with 0·2 g. of phenylhydrazine hydrochloride and 0·3 g. of sodium acetate for half an hour. The absence of dextrose is indicated by the absence of a precipitate in the hot liquid. If the result is doubtful, the liquid is cooled, the osazones are allowed to separate out, and their solubility is again tested by heating. All the pentosazone is re-dissolved but the glucosazone, once precipitated, does not go into solution on heating. The limit of sensitiveness is 0·032% of dextrose in the wort.—J. F. B.

Lipase. Palmer. *See* XII.

Patents.

Distilling alcoholic and other liquids; Process of ——. H. Wade. From J. Schneible. E.P. 182,832, 13.1.21.

The liquid is distilled in a column still, comprising a heater surmounted by cooled and uncooled dephlegmating plates, the heat supply to the heater being controlled to produce a constant temperature in the column above the heater and the supply of cooling medium to the cooled plates being controlled to produce a constant temperature at a fixed point in the column, whereby a uniform temperature gradient through the column is produced. The design of the plates is such as to maintain the interior of the still free from accumulations of reflux liquid, and baffles are introduced to impart a whirling or spiral movement to the mixed vapours and condensed liquid within the column. The fresh liquid is preheated and fed into the column at a point where the temperature and composition of the condensed liquid in the still is substantially the same as that of the preheated fresh liquid. The liquid is withdrawn from the still substantially at its boiling point.—H. C. R.

Sugar; Production of —— from wood and other material containing cellulose. Production of readily fermentable sugar solutions from material containing cellulose. A. Classen. G.P. (a) 351,681, 24.5.17, (b) 352,773, 23.3.18.

(a) The yield of fermentable sugar obtained from wood or other material containing cellulose by heating with sufficient hydrochloric acid or sulphuric acid to decompose the cellulose is increased by the addition of a small quantity of a catalyst consisting of another acid, or mixture of acids, or acid salts. Thus, if sulphuric acid or hydrochloric acid is used for decomposing the material, small quantities of hydrochloric acid and/or sulphur dioxide, or sulphuric acid and/or sulphur dioxide, respectively, are also added to the charge. (b) Wood or other material containing cellulose is heated with acids under pressure, steam being admitted into the apparatus until conversion begins, *i.e.*, at 130°—140° C., corresponding to a pressure of 3 atm., after which the supply of steam is regulated so that the pressure rises to about 7 atm. in 20—50 mins., this pressure then being maintained for a short time. A good yield of fermentable sugar is obtained by this procedure.—L. A. C.

XIXa.—FOODS.

Wheat starch; Some characteristics of ——. T. E. Wallis. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 82—83.

Wheat starch can be quite definitely recognised in barley starch by the presence of a number of grains measuring 40 microns and over. Starches consisting of large and small grains intermixed cannot, however, be characterised by the number of grains per mg., nor by the number of grains exceeding a certain size, unless they have been prepared by a standard process. In attempting the quantitative analysis of mixed flours microscopically, the pure starches must be prepared by a standardised process, which must also be used for the separation of starch from the mixed flour. For example, if the examination of the crude fibre of a flour has established the presence of barley in admixture with wheat, the amount of each present can be ascertained fairly accurately by preparing specimens of pure wheat starch and of starch from the mixed flour, by the standard process, and then making counts of the numbers of starch grains of 40 microns and over in the two samples. The result may then be checked by the examination of a mixture of genuine flours in the proportions found.—G. F. M.

Phosphates in milk; Volumetric determination of —— and application to the judging of milk. W. Müller. Mitt. Lebensmittelunters. u. Hyg., 1922, **13**, 52—63. Chem. Zentr., 1922, **93**, IV., 69.

Neubauer's modification of Leconte's uranyl nitrate method (Anleitung zur Harnanalyse, 5 Aufl., 152) was used. Different results were obtained by determining the phosphates in the milk serum (inorganic phosphates), to those obtained by incinerating the milk and determining the phosphates in the ash (total phosphates). The serum was obtained by Ambühl and Weiss' method (J., 1920, 464 a). The uranyl nitrate method was found to be simple and rapid and to give accurate results, especially with milk-serum. It can be of great use in judging milk, as the phosphate content of milk is lowered to a greater extent than the content of lactose by abnormalities of secretion, and forms by itself a clear indication of pathological changes in the milk.—H. C. R.

Milk; [Determination of] moisture content of dried ——. G. E. Holm. J. Assoc. Off. Agr. Chem., 1922, **5**, 509—511.

Accurate and concordant moisture determinations can be made on dried milk only if precautions are taken to guard the samples from contact with moisture whilst they are being handled. The samples should be stored in tightly sealed glass jars or metal containers, and weighed out in stoppered weighing bottles. For complete dehydration, drying for at least 1 hr. at 100° C. in a vacuum of about 25 in. is required.—G. F. M.

Milk foods; Analysis of ——. R. H. Crichton. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 94.

A simple and rapid method for the analysis of milk foods is described. 5 c.c. of the milk absorbed in absorbent paper, or an equivalent quantity of the solid food is dried in a steam-oven to determine the water and total solids, and the residue is exhausted in a Soxhlet apparatus to obtain the amount of fat and of solids not fat. To obtain the protein and carbohydrate content, 10 c.c. of the milk is mixed with water, and dialysed solution of iron (*Liq. Ferri Dial.*) is added until the supernatant liquid is quite clear. The volume is made up to 200 c.c., the precipitate filtered off, its nitrogen content determined by the Kjeldahl process, and the protein calculated. The filtrate contains the lactose which is estimated by means of Pavy's or Benedict's solution. Starch and cellulose interfere with the analysis by preventing the complete precipitation of the casein by the colloidal iron.—G. F. M.

θι-Decylenic acid, a previously unknown acid from butter. A. Grün and T. Wirth. Ber., 1922, **55**, 2197—2205.

Butter fat is treated with methyl alcoholic hydrogen chloride (1·5%) and the methyl esters are submitted to fractional distillation whereby a portion, b.p. 100°—140° C. at 15 mm., iodine value 9·8, is obtained. The fraction is hydrolysed and a partial separation of the saturated and unsaturated acids is effected by prolonged treatment of the corresponding lead salts in the usual manner. A mixture of approximately equal amounts of decylenic and capric acids is thus produced, which cannot be separated more completely by any of the ordinary methods. It is, therefore, esterified and the methyl esters are brominated in dry chloroform solution. The products are readily separated from one another by distillation under diminished pressure, whereby methyl dibromocaprate, b.p. 185°—186° C. at 7 mm., is obtained. Treatment of the latter with 5*N* methyl alcoholic hydrogen chloride and zinc yields methyl θι-decylenate, b.p. 115°—116° at 12 mm., which is hydrolysed to θι-decylenic acid, $CH_2{:}CH[CH_2]_7.CO_2H$, a colourless, fairly mobile liquid, b.p. 142° C. at 4 mm., m.p. below 0° C. The constitution of the acid is deduced from its conversion by ozone into azelaic acid and formaldehyde. This is the first instance on record of the isolation of an unsaturated acid of such low molecular weight or of one containing a terminal double bond from a natural fat.—H. W.

Soya bean milk. E. Remy. Z. Unters. Nahr. Genussm., 1922, **43**, 380—381.

A sample of soya-bean milk, yellowish-white in colour and having a sickly sweet taste and a faintly acid reaction, gave the following results on analysis: Water, 88·93%; dry matter, 11·07%; fat, 3·06%; non-fatty solids, 8·01%; protein, 2·96%; starch, 0·57%; glucose, 2·48%; mineral matter, 0·63%; alkalinity of ash, 6·44 c.c. of *N*/1 acid; germs per c.c., 4000. The gross energy content was 54 Cals. (cow's milk 70 Cals.). Content of food-units, 27 (cow's milk 34). The price of the soya bean milk at the time of the investigation was the same as that of cow's milk. It cannot therefore be considered to be an economical substitute for cow's milk.—H. C. R.

Chlorides in foodstuffs; Determination of ——. M. Bornand. Mitt. Lebensmittelunters. u. Hyg., 1922, **13**, 67—68. Chem. Zentr., 1922, **93**, IV., 66—67.

The organic matter is destroyed with persulphate and nitric acid. 2—5 g. or 10 c.c. of the sample is treated with 20—30 c.c. of water, 5—20 c.c. of concentrated nitric acid, and 20 c.c. of *N*/10 silver nitrate solution. The mixture is gently heated, and 1—5 g. of potassium persulphate is added in small portions until after boiling for 5—15 mins. the liquid is quite clear. If the sample is very rich in fat the whole of the fat and protein is not destroyed. The residue, however, remains in suspension and does not interfere with the titration. A small quantity of iron alum solution is added to the solution, which is diluted with 100 c.c. of water and titrated with *N*/10 thiocyanate. In order to prevent the oxidation of the chloride to chlorate 5 c.c. of formaldehyde or acetaldehyde is added towards the end of the reaction. This method is suitable for the analysis of urine, bread, milk, wine, meat extract, soup-cubes, and cheese. It is not suitable for butter.—H. C. R.

Phytin content of foodstuffs; Determination of ——. E. Arbenz. Mitt. Lebensmittelunters. u. Hyg., 1922, **13**, 45—52. Chem. Zentr., 1922, **93**, IV., 67.

The volumetric method of Heubner and Stadler (J., 1914, 713) was employed. The sample to be analysed was dried at 36° C. if necessary, finely ground, and freed from fat. A weighed quantity was then treated with a known volume of 0·6% hydrochloric acid, shaken, and filtered after standing for some hours. The residue was again extracted with hydrochloric acid and the extraction repeated until the filtrate was free from phytin. For each 20 c.c. of filtrate 10 c.c. of 3% ammonium thiocyanate was added, the volume made up to 100 c.c. with 0·6% hydrochloric acid, and the solution titrated with a standard solution of ferric chloride (0·05—2% Fe); 1 mg. Fe is equivalent to 1·19 mg. of phosphorus in the form of phytin. A large number of extractions are necessary to remove all the phytin from foodstuffs and the filtrations are tedious. The percentage of phytin, reckoned as anhydrous phytic acid, in the dry matter of various foodstuffs is given as follows: Rice bran, 4·232; rice flour, 0·216; wheat bran, 5·073; whole meal, 0·572; wheat flour, 0·208; maize flour, 0·857; lentils, 0·326; peas, 0·561; oatmeal, 0·506; cocoa, 2·230. No phytin was found in carrots, turnips, cauliflower, brussels sprouts, cabbage, spinach, asparagus, apples, pears, or figs. —H. C. R.

Cocoa; Torrefaction of ——. R. Lecoq. J. Pharm. Chim., 1922, **26**, 96—101.

The torrefaction of cocoa is accompanied by a loss in weight of 5—8% according to the duration of the operation. This loss is not due to a simple elimination of water, which in itself accounts for little more than half, or even less, of the total loss. Chemically, torrefaction involves a series of complex changes, which are manifested by an improvement in the aroma and taste, due to changes in the essential oils, and the destruction or modification of the acids of fermentation, and the tannins, by alterations in the colour resulting from the action of heat on the "cocoa red," and by the gelatinisation of the starch. A variation in the proportion of cacao butter as torrefaction proceeded was observed with certain varieties. At first owing to loss of water the percentage of fat rises, but falls again as the constituents of the cocoa are attacked. Finally a considerable rise again occurs indicating a selective destruction of constituents other than fat. Torrefaction is also accompanied by a notable increase in the proportion of substances soluble in water. The percentages of xanthine bases remain sensibly unaltered unless the heating is somewhat severe and prolonged.—G. F. M.

Proteins and derivatives; Recognition of —— by colour reactions. M. A. Rakusin. Biochem. Zeits., 1922, **130**, 268—281.

The author has examined a large number of vegetable and animal proteins, enzymes, and toxins, in respect of their behaviour to eight colour reactions, viz., the biuret, Millon, xanthoprotein, Liebermann, Adamkiewitsch, Molisch, Pettenkofer, and Ostromyslenski reactions; and the behaviour toward the sulphur reactions of Vohl and Rakusin. Each protein corresponds to a definite complex of reactions.—H. K.

Leucosin; Isoelectric point of the vegetable albumin ——. H. Lüers and M. Landauer. Z. Elektrochem., 1922, **28**, 341—347.

The isoelectric point of leucosin was determined by five different methods, with the following results: from the maximum of coagulation, $2·6\times10^{-5}$; from cataphoresis, $2·8\times10^{-5}$; from the maximum of alcohol precipitation, $2·7\times10^{-5}$; from the minimum of the internal friction, $2·3\times10^{-5}$; and from the maximum of the surface tension, $2·2\times10^{-5}$. The isoelectric point of serum-, vegetable-, and yeast-albumin is therefore the same, as also is the chemical composition; only in the biological properties is a marked difference to be found.—J. F. S.

Milk; Process of dissolving dried or concentrated ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 182,612, 28.4.21.

Dried milk is treated with 6—7 times its weight of water in a colloid mill (E.P. 155,836; J., 1922, 357 a). Oatmeal or other nutrient substances may be mixed with the milk previous to dispersing in the mill.—A. G. P.

Milk product; Method of producing a condensed- ——. H. S. Mellott, Assr. to The By-Products Recovery Co. U.S.P. 1,423,810, 25.7.22. Appl., 11.4.16.

Milk is subjected for a short time to a "disrupting temperature," the vapours generated being permitted to escape. The hot product is then subjected to the action of a cooling agent.—H. H.

Sulphite-cellulose waste liquor. G.P. 352,624. *See* V.

XIXb.—WATER PURIFICATION; SANITATION.

Water purification; Investigation, by means of the hydrogen electrode, of the chemical reactions involved in ——. R. E. Greenfield and A. M. Buswell. J. Amer. Chem. Soc., 1922, **44**, 1435—1442.

The shape and position of the neutralisation curves of the carbonates of sodium, magnesium, and calcium, using a strong acid, is unaffected by the metallic ion, but the inflection point occurs at a slightly higher p_H value in dilute solutions than in more concentrated solutions. The precipitation of magnesium as hydroxide commences at p_H 9·0 and is complete at p_H 10·6. Calcium carbonate is completely precipitated at p_H 9·5. Aluminium hydroxide commences to precipitate at p_H 4·0 and precipitation is complete at p_H 6·5—7·5; the precipitate commences to re-dissolve at p_H 8·0 and solution is complete at p_H 10·0—11·0. (*Cf.* J.C.S., Sept.)—J. F. S.

Water; Volumetric determination of sulphates in ——. J. Kuhlmann and J. Grossfeld. Z. Unters. Nahr. Genussm., 1922, **43**, 377—381.

This determination is best carried out by precipitating the sulphates with a known quantity of barium chloride, precipitating the excess of barium with a known quantity of potassium chromate, and titrating the excess of chromate iodometrically. Only one filtration is necessary, as the chromate has no action on the precipitated barium sulphate. All precipitations are carried out in cold solutions and the precipitates are retained on special "kieselguhr filter papers," which admit of rapid filtering. The method, which is described in detail, is easy to carry out, rapid, and accurate. —H. C. R.

Bacteria fermenting lactose, and their significance in water analysis. M. Levine. Iowa State Coll. Agric., 1921, **20** [31]. Bull. 62, 127 pages.

The whole of the colon group of organisms are characterised by the following reactions: formation of acid and of gas from monosaccharoses and from lactose; reduction of nitrates; production of acidity in, and clotting of, milk. All other tests vary with varieties of organisms. There is striking correlation in the results from the following tests:—(1) Gas ratio, (2) acidity to methyl red, (3) Vosges-Proskauer reaction, (4) growth in uric acid media, (5) appearance on agar media. These five tests serve to distinguish between members of colon organisms of the type *B. coli* and those of the aerogenes group. Tests (2) or, preferably, (3) may be used for the routine separation of the two subsections. A more detailed scheme is given for the differentiation of *B. coli, acidi-lactici, communior neapolitanum, coscoroba, aerogenes, and cloacae.* The aerogenes group are less indicative of recent pollution than *B. coli*, since they are more common in soil than in fæces and more persistent in water. Spore-forming lactose-fermenting organisms such as *Cl. melchii* and *Cl. enteritidis sporogenes* are considered to be of no value in detecting pollution of water supplies.—A. G. P.

Cresol in cresol soap solutions; Determination of ——. O. Schmatolla. Chem.-Zeit., 1922, **46**, 661—662.

The method previously described by Frank (J., 1922, 433 A) yields erroneous results, as no provision is made for neutralising the soap solution, which, if it contains free fatty acid, yields a portion of this to the ether, and if alkaline retains part of the cresol. Again, the cresol obtained cannot be freed from ether by evaporation of the latter at 100° C., or even at 150° C. Accurate results may be obtained by the following method: the soap solution is made slightly acid with sulphuric acid and distilled up to 250° C. or in a current of steam. The distillate is treated with a large excess of caustic potash, concentrated, and the cresol precipitated by acidifying the solution with hydrochloric acid and saturating it with salt in a graduated tube. The volume of cresol is then read off; it contains 6% of water.—A. R. P.

Hypochlorite solution; The effect of Dakin's —— *on certain organic substances.* N. O. Engfeldt. Z. physiol. Chem., 1922, **121**, 18—61.

The action of Dakin's hypochlorite solution on carbohydrates, fats, soaps and glycerol, proteins, amino-acids, ammonia, and aldehydes has been investigated. Fats, soaps, and glycerol react only to a small extent; most of the other substances investigated react much more completely and rapidly.—W. O. K.

Effluent spent liquors from the distillation of ammoniacal liquor; Treatment of ——. Fifty-eighth Annual Report on Alkali, etc. Works, 1921, 9—20.

Effluent spent liquor from an ammonia still was passed through the usual settling pits and then while still hot was passed down a scrubber, 18 ins. high and 5 ins. diameter, packed with coke. Waste furnace gases containing the equivalent of 1 grain H_2SO_4 per cub. ft. were passed up the scrubber, and it was found that, with a liquor feed of 160 c.c. per min., 85% of the phenols in the liquor could be volatilised and that the liquor could be decolorised as a result of the neutralisation of the alkali. In preliminary trials with a working scale plant, during which the supply of waste gases was inadequate, 56% of the phenols and 7·5% of the thiocyanate were removed, while the amount of oxygen required for the complete oxidation of the liquor was reduced by 31·5%. (*Cf.* J., 1922, 316 R; also *cf.* Skirrow, 1908, 58; Fowler and others, 1911, 174; Frankland and Silvester, 1907, 231.)—H. Hg.

Phenol in trade liquors; Estimation of ——. Fifty-eighth Annual Report on Alkali, etc. Works, 1921, 22—28.

When phenol is distilled from effluent spent liquors from ammonia distillation plants as in the method described by Skirrow (J., 1908, 58), the passage of the vapours through a flask containing a solution of sodium carbonate and lead carbonate maintained at the boiling point prevents the necessity of a second distillation, but leads to low results owing to the retention of phenol by the sodium carbonate solution. The catch flask may be omitted if 35 g. of salt and a slight excess of lead acetate solution are added to 100 c.c. of the liquor, rendered slightly acid if necessary, prior to the distillation. Volatilisation of acid is prevented by the addition of precipitated chalk. Liquors containing basic organic compounds must be evaporated with caustic soda prior to the distillation.—H. Hg.

Tellurium poisoning; A rare case of ——. W. Adolphi. Chem.-Zeit., 1922, **46**, 722.

Three cases of acute poisoning by tellurous acid

occurred during the smelting of some platinum mud which had been obtained as a by-product from Siberian gold ores containing as impurities tellurides of gold and silver. During the melting, the tellurous acid volatilised with the accompaniment of a white fume and a greenish flame. The symptoms observed in the victims were weakness, dizziness, greatly accelerated frequency of breathing and of the pulse, and a foul garlic-like odour of the breath, and in one case lasted 8—10 weeks.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Quinine and strychnine; Extraction of —— *from solutions of varying hydrogen ion concentration; a method for the separation of strychnine from quinine.* N. Evers. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 90—91.

In order to ensure complete extraction of strychnine as alkaloid from aqueous solution by chloroform, p_H must not be allowed to fall below 7, *i.e.*, the solution must be alkaline. Strychnine hydrochloride is dissolved to a considerable extent from acid solution by chloroform, the amount rising with increasing acidity, and 1% of strychnine hydrochloride in 2*N* hydrochloric acid can be completely removed by five extractions with chloroform. In the case of quinine the amount of hydrochloride extracted is diminishingly small with increasing acidity above p_H 3 and in 2*N* hydrochloric acid is practically nil, and hence the two alkaloids may be quantitatively separated by extracting the strychnine as hydrochloride from 2*N* hydrochloric acid solution, and then the quinine as alkaloid after rendering alkaline. For the complete extraction of quinine as alkaloid p_H must not be less than 8; with p_H 6—7 the whole of the quinine is extracted by chloroform, but partially as hydrochloride. At a greater acidity than p_H 4 there is a sudden reduction in the amount of hydrochloride dissolved, corresponding with the formation of the acid hydrochloride, and the quantity extracted rapidly becomes negligible. The above method of separation applied to the estimation of strychnine and quinine in Easton's syrup and iron quinine and strychnine citrates gives results which, although tending to be somewhat on the low side, are sufficiently accurate for ordinary purposes, and probably quite as accurate as those obtained by other more elaborate and tedious methods.—G. F. M.

Quinine salts; Rapid estimation of —— *in tablets.* S. G. Liversedge and F. W. Andrews. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 92—93.

Quinine in quinine salts or in tablets can be rapidly estimated by dissolving or extracting the alkaloidal salt with 20 c.c. of *N*/5 sulphuric acid, adding a known excess of *N*/2 sodium hydroxide, removing the liberated quinine with ether saturated with water, and subsequently titrating the excess of alkali with *N*/5 sulphuric acid, using phenolphthalein as indicator. If boric acid is present hæmatoxylin is used as indicator. Sugar, starch, gum, and talc, which may be present in quinine tablets, do not affect the accuracy of the determination.—G. F. M.

Scopoline. VI. Constitution of scopolamine and scopoline. The Hofmann degradation of scopoline. K. Hess and O. Wahl. Ber., 1922, **55**, 1979—2025.

dl-Scopoline can be esterified quantitatively with *r*-desoxytropic (α-phenylpropionic) acid with the formation of two racemic desoxytropylscopoleins, neither of which is identical with the single racemic compound (desoxyscopolamine) prepared by converting scopolamine by loss of water into aposcopolamine and reduction of the latter. The authors therefore consider that King's conception of the partially racemic nature of *l*-scopolamine is no longer tenable (*cf.* Chem. Soc. Trans., 1919, **115**, 476, 974); that scopoline is not present as such in the alcoholic component of *l*-scopolamine but is formed therefrom by structural change during hydrolysis, and that since desoxyscopolamine exists in only a single racemic form it contains only one asymmetric carbon atom and, as this is present in the tropyl group, it follows that the basic component is itself symmetrical in structure. Formulæ are proposed for scopolamine and scopoline respectively. (*Cf.* J.C.S., Sept.)—H. W.

Anhalonium alkaloids. IV. Synthesis of anhalamine. E. Späth and H. Röder. Monatsh., 1922, **43**, 93—111.

6-Hydroxy-7.8-dimethoxy-1.2.3.4-tetrahydroisoquinoline has been prepared synthetically and shown to be identical with anhalamine from the *Echinocactus Lewinii.* (*Cf.* J.C.S., Sept.)
—C. K. I.

Alkaloids; Report on ——. A. R. Bliss, jun. J. Assoc. Off. Agr. Chem., 1922, **5**, 564—573.

In the assay of strychnine in tablets or in liquids the volumetric check obtained by dissolving the isolated alkaloid in alcohol, adding excess of *N*/10 sulphuric acid and titrating back with *N*/50 potassium hydroxide, with methyl red as indicator, gave results in satisfactory agreement with the gravimetric determination. The method already published for the separation of quinine and strychnine (J. Assoc. Off. Agr. Chem., 1921, **4**, 416) was tested and gave much more accurate results than either the oxalate, tartrate, or ferrocyanide methods. The method for the determination of alkaloids in physostigma preparations already published (*loc. cit.*) gives more accurate results than the U.S.P. method. A modification of the official method for the assay of fluid extract of hyoscyamus, in which at least 30 c.c. of water and 5—10 c.c. of *Liq. Ammonia Fortior.* were used, and before titrating, the residue was treated twice with 5 c.c. of ether, evaporating to dryness each time, gave satisfactory results, higher than those obtained by the U.S.P. method. A preliminary report is made on the determination of the alkaloids of ipecacuanha, and attention is particularly drawn to the necessity of avoiding overheating in evaporating the ethereal extracts, otherwise decomposition of the alkaloids, notably of cephaeline, will cause a great discrepancy between the gravimetric and volumetric results. The last portions of ether should be evaporated spontaneously without heat, and the residue dried at a temperature not exceeding 60° C.—G. F. M.

Alkaloidal bismuthic iodides; Method for the preparation of —— in a crystalline form. M. François and L. G. Blanc. Comptes rend., 1922, **175**, 273—274.

Crystalline bismuthic iodides of caffeine, theobromine, morphine, codeine, quinine, atropine, arecoline, pilocarpine, sparteine, nicotine, aniline, pyridine, and quinoline were prepared from potassium bismuthic iodide and acid solutions of the hydrochlorides of the bases by methods precisely analogous to those employed for the preparation of the double mercuric iodides (J., 1922, 645 A). These compounds form extremely well-defined microscopic crystals, and in the bulk are considerably darker in colour than the corresponding amorphous substances. They contain no water of crystallisation, and have the general formula $(BiI_3)_x(Alk.HI)_y$. They appear to be adapted for the microchemical characterisation of the alkaloids.—G. F. M.

Microsublimation of plant products. A. Viehoever. J. Assoc. Off. Agr. Chem., 1922, **5**, 557—559.

The sublimation is conducted in a small beaker-like container with a small cup, about 1×1 cm., extending from the bottom. The cup containing the plant material, is heated in a cottonseed-oil bath to the desired temperature, and a small glass placed over the opening serves as a receiver for the sublimate. In this way santonin was obtained in characteristic crystalline form from *Artemisia cina* and *A. neo-mexicana*, and was identified further by the blue coloration with alcoholic furfural solution and sulphuric acid, and by the greenish precipitate with hydriodic acid—iodine. Caffeine was obtained from the leaves of *Ilex-cassine*, Michx., and was identified by the characteristic crystals produced under the micriscope on addition of mercuric chloride solution. From *Piper cubeba* needle-shaped crystals of cubebin were obtained, and identified by the blood-red coloration with sulphuric acid. Crystals of hydrastine were obtained from *Hydrastis canadensis.*—G. F. M.

Digitonin and its derivatives. A. Windaus and K. Weil. Z. physiol. Chem, 1922, **121**, 62—79.

The following formulæ are ascribed to the compounds previously investigated by Kiliani:—Digitonin, $C_{55}H_{90}O_{29}$; digitogenin, $C_{26}H_{42}O_5$; digitogenic acid, β-digitogenic acid, and digitoic acid, $C_{26}H_{38}O_7$; oxydigitogenic acid, $C_{26}H_{38}O_8$; digitic acid, $C_{26}H_{38}O_{10}$. (*Cf.* J.C.S., Sept.).—W. O. K.

Santonin; Occurrence of ——. H. G. Greenish and C. E. Pearson. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 85.

The leaves of *Artemisia brevifolia* gave on extraction with chloroform 1·09% of santonin calculated on the material dried at 100° C From *A. mexicana* and *A. redolens*, species occurring widely distributed in North and South Mexico, no santonin could be obtained by extraction of either the leaves or the stems, although Viehoever and Capen have reported its presence in these species (Amer. J. Pharm., 1922, **94**, 446). The leaves of *A. Abrotanum and A. vulgaris* were also examined for santonin but without positive results.—G. F. M.

Arsenic content of some of the marine algæ. A. J. Jones. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 86—87.

Seaweeds generally contain small proportions of arsenic, varying from about 0·01% in the coarser varieties, such as *Laminaria* and *Fucus sp.*, to as little as 0·0005% in the so-called edible seaweeds, such as *Chondrus crispus*, or Irish moss, and *Gigartina mammillosa*, the above percentages being calculated on the air-dried weed. These algæ readily yield a large proportion of their arsenic content to cold water, and in one case nearly one-sixth of the total amount was removed by contact with distilled water for 15 mins.—G. F. M.

Adrenaline; The comparative activity of racemic —— and l-adrenaline in increasing the blood-pressure. A. Richaud. J. Pharm. Chim., 1922, **26**, 81—86.

r-Adrenaline employed in very small doses of the order of 0·01 mg. increases the blood-pressure to a somewhat lesser degree than *l*-adrenaline, but the difference in activity is not by any means so great as has been supposed. It is not constant, but rarely exceeds 10—15%, with 25—30% as a maximum difference. As the dose is increased to 0·04—0·05 mg. the difference in activity disappears entirely, and as the usual therapeutic dose is from 0·04 to 0·1 mg. there is no disadvantage attendant on the use of the racemic compound, and the resolution of the synthetic substance into its optical isomerides is therefore quite unnecessary.
—G. F. M.

Thymine; Detection of —— in the presence of sugar. H. J. Deuel and O. Baudisch. J. Amer. Chem. Soc., 1922, **44**, 1581—1584.

Thymine is precipitated in the form of its mercury salt, from a solution which also contains sugar, by the addition of saturated mercuric chloride solution (10 c.c.) and sufficient sodium hydroxide solution to make the mixture decidedly alkaline. The precipitate is separated by centrifuging, and, after pouring off the supernatant liquid, is thoroughly mixed with distilled water (100 c.c.) and again centrifuged. It is then suspended in water (100 c.c.) and decomposed with hydrogen sulphide; the precipitated mercuric sulphide is filtered off and excess of hydrogen sulphide is removed by boiling the filtrate. The remaining liquid is cooled and made up to 100 c.c. Oxidation of the thymine is effected as described by Baudisch (Ber., 1921, **54**, 406), and the test is completed by the method of Johnson and Baudisch (J., 1922, 194 A). Thymine in quantities of 10—15 mg. may readily be detected in the daylight, whilst quantities as small as 1 mg. may be detected by the use of the iron arc light.—H. W.

Scammony resin; Ether-solubility of ——. H. Deane and W. E. Edmonton. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 82.

For the determination of the solubility of scammony resin in ether, extraction in a Soxhlet apparatus has been suggested, but to obtain concordant results by this method it is necessary to have the conditions of working very closely defined. Variations in the size of the extractor and the frequency of siphoning may lead to discordant results. Values varying from 76·7 to 97% were obtained

with the same sample of resin extracted with ether under different conditions in Soxhlet extractors.
—G. F. M.

Butylethylmalonylurea, a new hypnotic of the barbituric acid series. P. Carnot and M. Tiffeneau. Comptes rend., 1922, 175, 241—244.

A pharmacodynamical and clinical study was made of a new series of unsymmetrically disubstituted malonylureas. The hypnotic powers referred to that of diethylmalonylurea (veronal) as 10, were as follows:—Ethylmethylmalonylurea 5, ethylpropylmalonylurea 20, ethylbutylmalonylurea 30, ethylisobutylmalonylurea 30, ethylisoamylmalonylurea 30, ethylheptylmalonylurea 25. As in the symmetrically disubstituted series the members containing 10 and 11 C atoms are the most active, and the ethylbutyl-derivative appears to be particularly suitable for therapeutic use on account of its greater solubility in water, which renders it rapid in action and quickly eliminated. The toxicity of this derivative is proportional to its hypnotic activity, 18 cg. per kg. weight of animal being a lethal dose for a mouse, compared with 54 cg. of veronal. The normal dose of the ethylbutyl-derivative for a human being is 5—10 cg. subcutaneously, and 10—20 cg. *per os.*—G. F. M.

Platinum black; Catalysis by ——. G. Vavon and A. Husson. Comptes rend., 1922, 175, 277—279.

A platinum black catalyst which has become poisoned and inactive in the hydrogenation of a particular substance is not necessarily inactive towards another substance, and experiments were undertaken to determine the point at which absorption of hydrogen ceased with various unsaturated substances when the catalyst was progressively poisoned by the gradual addition of small quantities of carbon bisulphide. This limiting point was found to vary with the nature of the substance, with the nature of the solvent, with the quality of the platinum, and with the amount of the catalyst used, but to be independent of the concentration of the solution. In one instance using 5·5 g. of substance, 50 c.c. of alcohol, and 0·2 g. of platinum, the amount of carbon bisulphide required to inhibit hydrogenation was 1·1 mg. for cyclohexene, 0·8 mg. for nitrobenzene, 0·5 mg. for cinnamic acid, and 0·4 mg. for acetophenone, so that a catalyst which was inactive towards acetophenone would still hydrogenate nitrobenzene or cyclohexene.
—G. F. M.

Furfural; Estimation of small quantities of —— *colorimetrically.* P. Fleury and G. Poirot. J. Pharm. Chim., 1922, 26, 87—96.

Small quantities of furfural may be determined colorimetrically with an accuracy of about ±1%, by means of the blue coloration which is formed in an acidic medium with orcinol in a suitable solvent, preferably acetic acid. The reagents required are hydrochloric acid (sp. gr. 1·19) containing 0·02 c.c. of solution of ferric chloride per litre; glacial acetic acid containing 1 g. of orcinol in 1600 c.c., and a standard solution of furfural containing 1 g. in 10 l. of 1% acetic acid. 1 c.c. of the standard solution or of the solution under examination is mixed with 4 c.c. of the acetic acid-orcinol solution and 5 c.c. of the ferro-hydrochloric acid solution and warmed in a water bath for 1 minute. After keeping for 30 mins. the maximum coloration is developed, and comparison is made with the standard in a Duboscq colorimeter. The reaction has a sensitiveness of about 4 mg. of furfural per litre.—G. F. M.

Urea; Direct synthesis of —— *starting from carbon dioxide and ammonia.* K. C. Bailey. Comptes rend., 1922, 175, 279—281.

A yield of 14% of urea calculated on carbon dioxide was obtained by passing this gas with an excess of ammonia through a quartz tube, heated to redness, and traversed by a concentric glass tube through which cold water was circulated. The urea was deposited on the cool walls of the latter, and by using thoria or alumina as catalysts the yield was increased to 19%. By re-circulation of the unused carbon dioxide the yield was raised to 50% or more. Above 500° C. no urea was formed, and at 450° C. in presence of thoria, only a small quantity. As the experiments were conducted at atmospheric pressure and the product was always accompanied by a small amount of ammonium cyanate, ammonium carbamate cannot be considered to be an intermediate product, and it seems probable that the reactions occurring are represented by the equations:—$CO_2+NH_3=H_2O+HO.C{:}N$; $HO.CN \rightleftarrows H.N{:}CO$; $H.N{:}CO+NH_3=CO(NH_2)_2$; $HO.CN+NH_3=NH_4O.CN$.—G. F. M.

Sodium chaulmoograte or gynocardate; Preparation of ——. H. C. T. Gardner. Pharm. J., 1922, 109, 154—155.

Genuine *Taraktogenos Kurzii* (chaulmoogra) oil (80 pts.) is saponified with sodium hydroxide (14 pts.) by boiling for 6 hrs. with lye of 26° B. (sp. gr. 1·22). After cooling salt is added and the precipitated soap is removed, dissolved in cold water, and decomposed by the addition of 31 pts. of sulphuric acid (sp. gr. 1·530). The liberated fatty acids are dissolved in 80—90 pts. of alcohol, and the solution cooled to 8°—12° C. for some hours. The acids which separate are removed and the alcohol is distilled from the residue under reduced pressure. The dry fatty acids remaining should melt at 32°—34° C., otherwise the operation must be repeated until this m.p. is attained. The sodium salts prepared by exactly neutralising (to phenolphthalein) the alcoholic solution of these acids of m.p. 32°—34° C. with sodium hydroxide are satisfactory for therapeutic use, and are soluble in water. The dry salt is isolated by distilling off the alcohol *in vacuo* at a temperature not exceeding 80° C., and preferably lower, to prevent darkening. The dry salt should be stored in air-tight containers.
—G. F. M.

Potassium acetate; Oxidation of —— *to potassium oxalate.* W. L. Evans and P. R. Hines. J. Amer. Chem. Soc., 1922, 44, 1543—1546.

Potassium acetate may be oxidised to potassium oxalate with alkaline permanganate under certain definite conditions. The yield of oxalic acid is a function of the concentration of the reacting materials, the temperature, and the duration of the experiment.—H. W.

Peppermint oils; Differentiation of Japanese and American ——. E. O. Eaton. J. Assoc. Off. Agr. Chem., 1922, 5, 597—599.

Japanese peppermint oil derived from *Mentha arvensis* may be quickly differentiated from the oil of *Mentha piperita* by the following colour reaction: 5 drops of the oil and 1 c.c. of glacial acetic acid are heated with 1 drop of nitric acid in a water bath to about 60° C. for about 2 mins. A violet or bluish colour develops in *M. piperita* oil in a few minutes when observed by transmitted light, and a copper-coloured fluorescence by reflected light. Japanese oils usually show a straw colour or sometimes a very faint blue colour, but no copper-coloured fluorescence. The method of storage of *M. piperita* oils has some effect on the reaction, oils stored in open vessels in sunlight giving a negative result after a few months, but in every case oils which had lost their ability to give the reaction recovered the property on being treated with nascent hydrogen and subsequently steam distilled. Japanese oils treated in the same way *still gave a negative test. The refractive index* and the sp. gr. of Japanese oils are lower than those of *M. piperita* oils, and the odour and taste are also inferior.—G. F. M.

Patents.

Colloidally soluble substances and of suspensions or emulsions; Process for the manufacture of ——. L. Lilienfeld. E.P. 156,725, 7.1.21. Conv., 1.8.19.

Water-soluble alkyl or aryl ethers of polysaccharides of the empirical formula $(C_6H_{10}O_5)_n$ such as cellulose or its conversion products or derivatives, starch, dextrin, inulin, lichenin, or the like, or mixtures of these ethers, with or without the addition of other protective colloids, are used as protective colloids in the preparation of colloidal solutions, suspensions, or emulsions, especially for therapeutic purposes. For example, 200 pts. by weight of a 5—10% solution of an ethyl- or methylcellulose, or ethyl- or methyl-starch, is mixed with a solution of 5—7 pts. of silver nitrate in 5—7 pts. of water, and 250 pts. of 10% ammonia and 200—250 pts. of 6—8% ammonium formate solution are added. The mixture is heated for some time, cooled, dialysed, and either evaporated *in vacuo* or precipitated by the addition of alcohol or the like, and the precipitate is separated and dried. —L. A. C.

Colloids and colloidal solutions; Process for preparing ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 182,696, 15.7.21.

Colloidal solutions of elements such as silver, gold, mercury, platinum, palladium, lead, sulphur, selenium, arsenic, and the like, are prepared by a process of combined precipitation and dispersion in a colloid mill as described in E.P. 155,836 (J., 1922, 357 A). For example, a mixture of 169 pts. of a 1% silver nitrate solution and 3·4 pts. of 10% ammonia is treated in a colloid mill in the presence of 3 pts. of agar-agar and 30 pts. of 1% formaldehyde, the constituents being added drop by drop. Dissolved salts, such as ammonium nitrate, are removed, and a more permanent and concentrated solution is obtained by subjecting the solution to ultra-filtration at high pressure as described in E.P. 155,834 (J., 1922, 619 A).—L. A. C.

Saccharin; Manufacture of ——. H. Lowe. E.P. 174,913, 5.1.22. Conv., 31.1.21.

Saccharin is obtained in a yield largely exceeding 75%, when *o*-toluenesulphamide suspended in a 2*N* solution of sodium carbonate or bicarbonate is subjected to anodic oxidation with a current of 12 volts and a density of 0·04 amp. per sq. cm. If desired lead, cerium, or manganese compounds or ammonia may be added to the electrolytic bath.—G. F. M.

CC-Isopropylallylbarbituric acid; Manufacture of ——. H. R. Napp. From F. Hoffmann-La Roche & Co. E.P. 181,247, 30.6.21.

Isopropylallylbarbituric acid is obtained in 80% yield by the action of allyl bromide (130 pts.) on a solution of isopropylbarbituric acid (170 pts.) in 500 pts. of water and 135 pts. of 30% sodium hydroxide at 25° C. for 12 hrs. The product is filtered off and crystallised from dilute alcohol. It is sparingly soluble in water, readily soluble in alcohol and ether, and melts at 137°—138° C. —G. F. M.

Cinchona alkaloids and their derivatives; Preparation of amino-derivatives of hydrogenated ——. Howards and Sons, Ltd., J. W. Blagden, and M. Nierenstein. E.P. 182,986, 6.5.21.

Good yields of the amino-derivatives of hydrogenated cinchona alkaloids are obtained by reducing the nitro-derivatives in neutral or nearly neutral solution with suitable reducing agents, such as zinc or iron, in conjunction with a neutral salt. Thus nitrohydroquinine, dissolved in alcohol, or in water in the form of a salt, is heated to 50° or more, and zinc dust and aqueous ammonium sulphate solution are added. After stirring for some hours at this temperature the filtered solution is concentrated *in vacuo* to crystallise the product. —G. F. M.

Hydrocarbon mixtures; Treating gaseous ——. *Process of treating gaseous mixtures. Process of separating ethylene and other components from gaseous mixtures containing the same.* G. O. Curme, jun., Assr. to Union Carbide Co. U.S.P. (A) 1,422,182, (B) 1,422,183, and (C) 1,422,184, 11.7.22. Appl., (A) 5.6.19, (B) 4.5.20, (C) 20.4.17. (C) Renewed 1.12.20.

(A, B) A relatively soluble component is separated from a mixture of hydrocarbons or other gases by compressing the mixture and bringing it in contact with a suitable solvent liquid at a temperature below that of the atmosphere. Residual gases are withdrawn, and the solvent power of the liquid is progressively reduced to liberate the less soluble gases from solution, the gases liberated being brought in contact with portions of the liquid having progressively higher solvent power, and finally returned to the absorption apparatus. The relatively soluble component is separated from the solvent by reducing the pressure on the solution. (C) Ethylene is separated from gaseous mixtures containing it by the process described under (A, B). —L. A. C.

Diphenylguanidine; Process of making ——. M. L. Weiss, Assr. to Dovan Chemical Corp. U.S.P. 1,422,506, 11.7.22. Appl., 2.7.21.

Diphenylguanidine containing carbodiphenylimide as an impurity is dissolved in hot toluene, the solution is cooled, and the crystals are separated, washed with pure toluene, and dried.—L. A. C.

Secondary alcohols; Process of purifying higher ——. R. B. Lebo, Assr. to Standard Oil Co. U.S.P. 1,422,583, 11.7.22. Appl., 16.2.21.

Isopropyl alcohol is separated from mixtures containing it, and higher secondary alcohols by adding at least sufficient benzene to the mixture to form a low-boiling mixture with the isopropyl alcohol, and subsequently separating the low-boiling mixture by fractional distillation.—L. A. C.

Hydrocarbons; Process of chlorinating gaseous —— *and recovering products therefrom.* G. O. Curme, jun., Assr. to Carbide and Carbon Chemicals Corp. U.S.P. 1,422,838, 18.7.22. Appl., 7.7.20.

A mixture of a halogen gas and an excess of a hydrocarbon gas is caused to react with the liberation of a gaseous halogen acid, and reaction products of higher boiling point than the hydrocarbon are separated by anhydrous liquefaction from the mixture of gases obtained. The residual unchanged hydrocarbon is returned for further treatment.—L. A. C.

Dicyanodiamide; Method of making ——. H. C. Hetherington and J. M. Braham. U.S.P. 1,423,799, 25.7.22. Appl., 28.6.21.

Calcium cyanamide is extracted with water, and the solution is filtered. Sufficient sulphuric acid

is added to the solution to combine with one-half of the calcium present, the calcium sulphate formed is separated, more sulphuric acid is added, in finely-divided streams, calcium sulphate is again removed, and dicyanodiamide is recovered.
—L. A. C.

Dicarboxylic acids; Production of ——. A. G. Williams, Assr. to The Barrett Co. U.S.P. 1,423,980, 25.7.22. Appl., 22.3.21.

An aromatic compound containing a diketone group forming part of a carbocyclic ring structure is dissolved in an alkaline reducing solution, and the solution is oxidised.—L. A. C.

[*Maleic acid;*] *Purification of substances* [*e.g.* ——] *by distillation with a solvent.* G. C. Bailey, C. W. Fischer, and J. F. W. Schulze, Assrs. to The Barrett Co. U.S.P. 1,424,138, 25.7.22. Appl., 9.2.21.

Maleic acid containing benzoquinone as impurity is purified by distillation in the presence of xylene.
—L. A. C.

Chlorinated nitronaphthalenes; Preparation of ——. O. Matter. G.P. 348,069, 14.1.19.

The products obtained by treating chlorine addition products of naphthalene with nitric acid are treated with ammonia or mixtures which liberate ammonia. Dry ammonia gas is led into a solution of nitronaphthalenetetrachloride in methyl alcohol, or a mixture of ammonium chloride and calcium hydroxide is added to the solution. The product is separated by filtration, washed with water, and purified by distillation under reduced pressure and crystallisation from methyl alcohol, yielding 5.8-dichloro-1-nitronaphthalene, m.p. 94° C.
—L. A. C.

Betaine and other organic bases; Production of pure ——. Akt.-Ges. f. Anilin-Fabr. G.P. 348,380, 18.4.17, and 348,381, 14.6.17.

Solutions of betaine or other organic bases which contain an excess of base or acid are treated in the cathode chamber of an electrolytic cell until the anions of the acid are completely removed. The solution of betaine obtained thereby is either used direct, or the betaine is separated or converted into salts. The process is not applicable for purifying strong bases, such as tetra-alkylammonium bases.
—L. A. C.

Basic aluminium salts containing silicic acid; Preparation of solutions of ——. *Preparation of solid mixtures containing basic aluminium acetate or aluminium salts containing silicic acid.* Lecinwerk E. Laves. G.P. (A) 348,411, 19.9.20, 349,984, 16.11.20, and 351,732, 24.12.20, (B) 351,731, 7.12.20.

(A) Colloidal aluminium silicate, prepared by the addition of aluminium sulphate to solutions of soluble silicates, is dissolved in a mixture of dilute hydrochloric or sulphuric acid and acetic acid or other organic acids, such as lactic acid, formic acid, tartaric acid, aldehydesulphurous acid, or mixtures of these acids with acetic acid, more aluminium sulphate and calcium carbonate are added to the solution, and calcium sulphate is separated by filtration. For example, water-glass diluted with water is added to a mixture of dilute hydrochloric acid and 96% acetic acid; aluminium sulphate and calcium carbonate are added to the solution, which is then stirred for several hours and filtered. The clear solution contains about 1·5% of colloidal silicic acid and 8% of aluminium acetate, *i.e.*, 1 mol. of SiO_2 to 2 mols. of $Al(OH)(CH_3CO_2)_2$, does not gelatinise on standing for 1 year, and possesses the properties of colloidal silicic acid in stimulating leucocytosis and the formation of connective tissue. The sodium chloride present in the solution has usually no harmful effect, but can be separated by dialysis after the addition of a little acetic acid, or solutions containing no alkali salts can be prepared without dialysis by adding aluminium sulphate to solutions of water-glass diluted with distilled water, the precipitate formed after filtration and washing with water, being dissolved in a mixture of dilute sulphuric acid and 96% acetic acid, and subsequently treated as described above. (B) Starch, amylodextrin, vegetable mucilage, the extracts of quince seeds, linseed, and the like, or other protective colloids, with or without the addition of inactive substances, such as talc or lycopodium, are added to solutions prepared as described in (A), and the mixtures are dried at low temperatures *in vacuo*. The products can be used in the form of powder or may be added to ointments, and on account of the ready solubility of the active constituents, possess the same therapeutic properties as the solutions.—L. A. C.

Aromatic selenium compounds; Preparation of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 348,906, 26.1.19, and 350,376, 18.2.19. Addns. to 299,510.

Aromatic compounds are treated with selenic acid, instead of with selenium or selenium dioxide as described in the chief patent, in the presence of concentrated sulphuric acid or other suitable solvents. A product containing 16% Se is prepared by treating *o*-nitrophenol with selenic acid in the presence of sulphuric acid; antipyrine on similar treatment yields a product, m.p. about 238° C., containing 17% Se. The compound diantipyrilselenide described in the chief patent can be prepared by treating an aqueous solution of antipyrine or the base itself with selenious acid or with 67% aqueous selenic acid. Solutions of *p*-nitroantipyrine in formic acid and *p*-tolylantipyrine in ethyl alcohol on heating with solutions of selenium dioxide in the same solvents yield respectively di-*p*-nitroantipyrilselenide, m.p. about 260° C. (decomp.), and di-*p*-tolylantipyrilselenide, $(C_{12}H_{13}ON_2)_2$ Se, m.p. about 255° C. (decomp.).
—L. A. C.

Carbonic acid esters of monohydric alcohols; Preparation of ——. C. F. Boehringer und Soehne G.m.b.H. G.P. 349,010, 29.1.21.

One mol. of carbonyl chloride is added to 2 mols. of a monohydric alcohol, or a mixture of monohydric alcohols, in the presence of dialkylaniline, and the mixture is allowed to stand for several hours. The desired neutral ester is obtained in almost quantitative yield. The process can be employed for the production of neutral esters of aliphatic, aromatic, or hydroaromatic alcohols, *e.g.*, benzyl alcohol and menthol. An example is given describing the preparation of diethyl carbonate by the action of carbonyl chloride on ethyl alcohol below 30°—40° C. in the presence of dimethylaniline and benzene.—L. A. C.

Di- and polyhalogen substitution products of monohydric phenols; Preparation of ——. Akt.-Ges. f. Anilin-Fabr. G.P. 349,794, 29.7.14. Addn. to 281,175 (J., 1915, 543).

Tri- or polyhalogen substitution products of aromatic hydrocarbons are heated under pressure with alkali hydroxides and methyl alcohol, or its homologues, with or without the addition of other solvents. 1.2.4.5-Tetrachlorobenzene on heating under pressure to 160° C. for 7 hrs. with sodium hydroxide and methyl alcohol, with or without the addition of pyridine, or to 200° C. for 10 hrs. with potassium hydroxide and ethyl alcohol, or to 200° C. for 16 hrs. with potassium hydroxide and amyl alcohol, yields 2.4.5-trichlorophenol, m.p. 64°—65° C. The corresponding tribromo compound has m.p. 80° C. 1.2.4-Trichlorobenzene on heating under pressure for 4 hrs. at 180°—190° C. with sodium hydroxide and methyl alcohol yields 2.5-dichlorophenol, b.p. 211° C., m.p. 58° C. The product obtained by treating 60 pts. of naphthalene with 320 pts. of bromine at 100° C., on heating at 150° C. under pressure for 6 hrs. with sodium hydroxide and methyl alcohol, yields a resinous mixture of polybromohydroxynaphthalenes. The products are of value as germicides.—L. A. C.

Serums, vaccines, and the like; Process for sterilising ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 349,806, 11.9.18.

Complex organic mercury compounds which are soluble in water and which have no chemical action on proteins, *e.g.*, complex aliphatic or aromatic mercurycarboxylic acids, or oxymercurycarboxylic acids, or their anhydrides or salts, or derivatives of these compounds, such as sodium oxymercurysalicylic acid, sodium oxymercuryacetic acid, salts of mercury fatty acids, and mercuriated aryloxy fatty acids, are suitable for sterilising serums, vaccines, and the like. Such compounds are superior to mercuric chloride for sterilising purposes, and have no injurious effect on the serums and vaccines.—L. A. C.

2-Phenylquinoline-4-carboxylic acid; Process for manufacture of derivatives of a hydrogenated ——. Chem. Werke Grenzach A.-G. G.P. 351,464, 18.12.17.

The derivatives are produced by electrolytic reduction of 2-phenylquinolinecarboxylic acid in alkaline solution, or by the use of an alkaline reducing agent, the resulting hydrogenated acid being converted by the usual methods into esters, or into N-alkyl or N-acidyl derivatives and the latter into esters. The crystals of the hydrogenated acid produced by cathodic reduction of 2-phenylquinoline-4-carboxylic acid have m.p. 167° C., and give, on esterification with alcohol and concentrated sulphuric acid, the ethyl ester as white needles, m.p. 83° C., soluble in the usual organic solvents, but insoluble in dilute alkaline solutions. The methyl ester of hydro-2-phenylquinoline-4-carboxylic acid crystallises from methyl alcohol in colourless needles, m.p. 99° C. If the hydrogenated acid is heated with acetic anhydride and several drops of concentrated sulphuric acid under a reflux condenser, it is converted into the N-acetyl-hydro-2-phenylquinoline-4-carboxylic acid, m.p. 209° C. The acetyl derivative is soluble in the usual organic solvents and in dilute alkaline solutions. These compounds stimulate reflex action and are therefore of use for treating diseases of the nervous system.
—A. G.

Cells, parasites, tissues, and organs; Process for decomposition and extraction of ——. Tetralin Ges.m.b.H. G.P. 349,807, 20.2.21.

The organs are treated with hydronaphthalenes, either alone or in admixture with other substances. The substances are treated with a quantity of hydronaphthalene (or its derivatives) insufficient for complete solution, and the insoluble matter is separated. The bacilli of tuberculosis and typhoid bacteria are rendered soluble by the action of hydronaphthalene, whilst large organs, *e.g.*, the brain, can also be made to dissolve, yielding clear solutions. If more than 4 mg. of tubercle bacilli are treated with 1 c.c. of tetrahydronaphthalene, the insoluble residue, after separation from the solution, yields a new, easily resorbable product, which is highly serviceable for diagnosis, inoculation and therapeutic purposes.—A. G.

Crotonaldehyde; Preparation of ——. Consortium für elektrochem. Ind. G.m.b.H. G.P. 349,915, 30.11.19.

Acetaldehyde vapour, at a temperature below 300° C., is led through a contact chamber containing heated metal oxides, such as wood charcoal coated with titanium oxide, or blocks of aluminium oxide or hydroxide, beryllium oxide, calcium hydroxide, bog iron ore, cement, or mixtures of these, at such a velocity that the acetaldehyde is only partially converted into crotonaldehyde. The unchanged acetaldehyde is separated from the product, *e.g.*, by fractional distillation or blowing, and is then mixed with the vapour admitted to the chamber.—L. A. C.

Drugs; Production of extracts of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 350,122, 4.4.20.

Acetamide or formamide is used as the extracting medium, either in the molten state or in solution. The extracted products have a better taste than those extracted with aqueous or alcoholic solutions, and in many cases contain a larger proportion of active substance. They are quite stable and are not liable to take fire. Extracts produced with the aid of acetamide can be concentrated, and converted into pulverulent or tabloid form, whilst formamide is used for the production of liquid extracts. Solutions of the drugs can be made with greater facility in aqueous solutions of formamide or acetamide than in diluted alcohol of the same concentration.—A. G.

Dialkylamides of pyridine-3-carboxylic acid (nicotinic acid); Preparation of ——. Ges. f. Chem. Ind. in Basel. G.P. 351,085, 14.9.20.

Pyridine-3-carboxylic acid dialkylamides, which are of therapeutic value owing to their property of raising the blood pressure and regulating the central nervous system, are prepared by treating compounds containing the pyridine-3-carboxylic acid nucleus, *e.g.*, the acid halides, with secondary aliphatic amines, such as diethylamine, dipropylamine, diamylamine, or piperidine. Pyridine-3-carboxylic acid dipropylamide, diamylamide, and piperidide have b.p. 184° C. under 17 mm., 210° C. under 20 mm., and 310° C. respectively.—L. A. C.

Bile acid; Preparation of an unsaturated ——. J. D. Riedel A.-G. G.P. 352,129, 24.3.17.

The acid prepared as described in G.P. 334,553 (J., 1921, 529 A), is treated with bromine, and the product is treated with alkalis. For example, bromine is added, drop by drop, to a cooled solution of the acetic acid compound of apocholic acid in acetic acid or methyl alcohol, the oily dibromide produced is heated with a dilute alkaline solution until dissolved, and an unsaturated bile acid, m.p. 245°—247° C. after recrystallisation from acetic acid, is precipitated by the addition of dilute hydrochloric acid to the solution. The product has a strong antiseptic action and is of therapeutic value.—L. A. C.

Medicinal solutions; Production of oily ——. Byk-Guldenwerke Chem. Fabr. A.-G. G.P. 352,364, 27.9.17.

For compounding non-oily substances such as iodoform, salicylic acid, phenol, iodine, camphor, naphthalene, menthol, soaps, etc., esters of the higher fatty acids, which are fluid at normal temperatures, are used as solvent. The ethyl, methyl, and propyl esters of linolic acid and the alkyl esters of oleic acid and palmitic acid are better solvents for solid medicinal substances than the natural glycerides. The solutions made with the alkyl esters are easily absorbed and can therefore be used for injection purposes. Substances such as mercuric chloride and alkaline earth and heavy metal soaps, which are quite insoluble in linseed oil, are soluble in the alkyl esters.—A. G.

Hydrated magnetic oxide of iron; Production of finest ——. H. Spude. G.P. 352,365, 27.11.19.

Precipitated and elutriated ferrosoferric oxide is stirred with gum arabic and water without previous drying, and disintegrated (atomised) under pressure. After settling of the coarser material the suspension of the finest particles is concentrated by draining off the liquid with the aid of suction. The product mixed with water is used for injections for the treatment of cancerous affections.—A. G.

Carbon compounds; Process [catalysts] for hydrogenation and dehydrogenation of ——. Badische Anilin- u. Soda-Fabrik. G.P. 352,439, 16.11.13. Addn. to 307,580.

Combined silica or an alkali silicate is used as activating substance. The catalyst is highly insensitive to catalyst poisons, has a long life, and possesses a high reaction efficiency. Pumice is made into a paste with nickel carbonate and a solution of water-glass. After drying, the mass is reduced with hydrogen at 300°—350° C. With the aid of this catalyst, phenol can be converted continuously at 100°—120° C. into cyclohexanol, without the formation of by-products. In place of nickel, copper or mixtures of nickel and aluminium may be used. The catalyst can also be used for the production of methylcyclohexanone from methylcyclohexanol, aniline from nitrobenzene, and for the hydrogenation of oils.—A. G.

Carboxylic acids of the purine series; Preparation of ——. E. Merck, O. Wolfes, and E. Kornick. G.P. 352,980, 25.4.20.

Salts of mono- or dialkylated xanthine are treated with salts of monohalogenated aliphatic carboxylic acids, yielding N-alkylcarboxylic acids of mono- and dialkylated xanthine which are of therapeutic value. For example, sodium-theobromine and theophylline on heating with monochloroacetic acid in aqueous alkaline solution yield respectively theobromine-1-acetic acid, m.p. 260°., and theophylline-7-acetic acid, m.p. 266° C., and sodium 3-methylxanthine on heating with β-iodopropionic acid, first to 100° C. and then to 105° C., yields 3-methylxanthinepropionic acid, m.p. 308°—309° C. (decomp.).—L. A. C.

Monohydroxyethyl catechol ether; Process for manufacture of ——. Chem. Werke Grenzach A.-G. G.P. 352,983, 27.7.19.

Either ethylene-halogenhydrin is allowed to react with the acid alkali salts of catechol, or ethylene oxide is treated with free catechol. For example, a solution of catechol in 40% caustic soda is heated with ethylene-chlorhydrin to 100° C., or catechol is heated with ethylene-oxide under pressure to 140°—150° C. The ether, $C_6H_4(OH)(O.CH_2.CH_2OH)$ crystallises from water or benzene, has m.p. 99°—100° C., and gives with a drop of ferric chloride a temporary violet colour which changes almost instantaneously to yellowish-red.—A. G.

Esters of dioxydiethylsulphide and process of making same. G. Kränzlein and M. Corell, Assrs. to Farbw. vorm. Meister, Lucius, und Brüning. U.S.P. 1,422,869, 18.7.22. Appl., 2.7.21.

See E.P. 154,907 of 1920; J., 1922, 309 A.

sym-Octohydro-anthracene and -phenanthrene. G.P. 352,721 and 352,719. *See* III.

Catalyst for hydrogenation. G.P. 352,431. *See* XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[Photographic] sensitisers for the deep red; New ——. C. E. K. Mees and G. Gutekunst. Brit. J. Phot., 1922, **69**, 474—475.

The methods of preparation and properties of three sensitising dyes, Naphthacyanole, Acetaminocyanole, and Kryptocyanine are described. Naphthacyanole shows a maximum at 690μμ, and a sensitising power for green less than Pinacyanol; it can be added to the emulsion or used as a bath for plates. Acetaminocyanole, when added to the emulsion gives a maximum at 730μμ, but when used in solution for bathing plates, entirely different results are obtained. Kryptocyanine is the most powerful sensitiser known and gives a maximum at 760μμ. It is useless for infra-red work at wavelengths above 900μμ, and confers no green sensitiveness.—W. C.

Latent [photographic] image; Conductivity of the ——. A. G. Rabinovich. J. Phys. Chem., 1922, **26**, 577—590.

The electrical conductivity of a dry "Premo" photographic film, 5×10 mm. is 10^{-11} ohm^{-1}/cm. at 18°—20° C. and has a temperature coefficient of 10% per degree, whilst the specific conductivity of a silver bromide gelatin emulsion is $8·0\times10^{-4}$ ohm^{-1} at 22° and the temperature coefficient is 3% per degree. These values are unchanged by exposing the films or emulsions.—J. F. S.

[Photographic] development; Grain structure v. light quanta in the theory of ——. W. Clark. Brit. J. Phot., 1922, **69**, 462.

"Reduction centres" from which development of the silver halide grains of an emulsion proceeds may be rendered visible by treatment with 10% sodium arsenite solution and partial development with ordinary developers, in absence of light. The centres thus shown follow the same laws of distribution among the grains as those made visible by the action of light and X-rays. This indicates that the centres are an essential part of the grain structure and that light action is not necessary for their formation.—W. C.

Actinometer with electrodes of mercury halides or sulphides. G. Athanasiu. Comptes rend., 1922, **175**, 214—217.

Mercury covered with very thin layers of mercurous halide or mercuric sulphide can be used in the same way as silver salts as electrodes in an electro-actinometer, and measurements were made of the E.M.F. generated by the illumination of one electrode of such an actinometer by the light of a mercury vapour lamp. The results for the various salts in different electrolytes are given, from which it appears that the light increases the potential of the halogenated electrodes, and diminishes that of the mercuric sulphide electrode. The most sensitive films were those of mercuric iodide prepared by treating mercury with a dilute alcoholic solution of iodine. Perfectly pure mercury is insensitive to light.—G. F. M.

Patents.

X-ray photography [; Intensifying screen for use in ——]. N. E. Luboshez. E.P. 182,496, 5.1.21.

An intensifying screen consisting of a sheet of opaque material coated with calcium tungstate or similar material is caused to adhere to the back of the emulsion-bearing base of an X-ray photographic film or plate by means of rubber, or various resins or waxes, so that the screen may be readily separated when desired without being wetted. If desired, an intensifying screen may be likewise applied to the emulsion surface.—J. S. G. T.

X-ray plates; Preparation of ——. Kranseder und Co. G.m.b.H., and Lüppo Cramer. G.P. 348,661, 30.12.20.

In X-ray plates having a film of silver bromide, this film is treated with desensitising agents which reduce its sensitiveness to light rays but have no influence on its sensitiveness to X-rays. Suitable desensitisers are aminophenols, diamines, and dyestuffs containing amino groups, or substituted amino groups, such as phenylenediamine, N-dimethyl-*p*-phenylenediamine, carbazoleleucoindophenolsulphonic acid, *p*-amino-*p*-hydroxydiphenylamine, Safranines, Brilliant Rhoduline Red, Methylene Blue, Auramine, Brilliant Green, Chrysoidine, and Vesuvine. The desensitising effect of dyestuffs is purely chemical, and is independent of the shade. Methylene Blue possesses the strongest desensitising action, but red and yellow dyestuffs which dye yellow and red shades appearing bright in the light of the dark room give the best results. The desensitising agent may either be added to the silver bromide-gelatin emulsion before coating the plates, or the coated plates may be steeped in a solution of the desensitiser.—L. A. C.

Photographs; Production of coloured ——. P. von Ditmar. G.P. 350,005, 13.1.21.

An alcoholic solution containing an aniline dyestuff with a metallic lustre and a substance which causes the dyestuff to remain amorphous on drying the solution, is poured on to a hot sheet of glass or the like. When dry, the plate is placed under a negative or diapositive, exposed to light, and subsequently treated successively with a bath containing chlorides or sulphates, potassium carbonate solution, and a solution of calcium hypochlorite or is exposed to the action of chlorine gas. For example, thymol, pyrogallol, or pyridine, is added to an alcoholic solution of Fuchsine, and the solution is poured over heated glass or paper into which the colour cannot penetrate. On exposure to light, the colour begins to crystallise, and after exposure, the plate is rapidly developed by treatment in the solutions described above. If treatment with potassium carbonate is omitted, silver images on a dark ground are obtained.—L. A. C.

Developing paper; Process for the manufacture of photographic ——. O. Mente. G.P. 351,322, 11.1.21.

Between the paper and the sensitive film a layer of colour is interposed, which absorbs chemically active rays, but is inert to the silver halide layer, and which can be subsequently destroyed or washed out. Certain red colouring matters, potassium permanganate, and manganese dioxide can be used for this purpose.—A. G.

Composition for coating metals for the purpose of permitting electric currents to operate by the action of light. H. L. Falk, Assr. to L. D. Wood. U.S.P. 1,424,088, 25.7.22. Appl., 10.12.21.

A mixture of crystals of platinum-barium-cyanide of potassium, crude sulphur, sodium tungstate, calcium chloride, and selenium crystals forms a composition for coating surfaces for the purpose of permitting electric currents to operate by light action.—W. C.

Photographic images; Process for treating and dyeing —— *and products obtained thereby.* W. Van D. Kelley. E.P. 160,137, 11.3.21.

See U.S.P. 1,411,968 of 1922; J., 1922, 393 A.

Photographic materials; High-temperature development of ——. A. J. Agnew and F. F. Renwick, Assrs. to Ilford, Ltd. U.S.P. 1,424,062, 25.7.22. Appl., 28.2.19.

See E.P. 128,337 of 1918; J., 1919, 602 A.

XXII.—EXPLOSIVES; MATCHES.

Nitration of aromatic substances; Rôle of mercuric nitrate in the "catalysed" ——. *Nitration of naphthalene.* T. L. Davis. J. Amer. Chem. Soc., 1922, **44**, 1588—1591.

Concentrated nitric acid, even in the presence of mercuric nitrate, converts naphthalene into nitronaphthalenes, the amount of nitronaphthols formed being exceedingly small. The best conditions for the direct production of the latter from naphthalene consist in the use of moderately dilute acid and moderately low temperature; in addition to nitronaphthalenes, 2.4-dinitro-α-naphthol and probably 2-nitro-α-naphthol are obtained. The unexpected formation of substituted α-naphthols renders the interpretation of the course of the action a matter of considerable difficulty.—H. W.

Patents.

Explosive. C. J. S. Lundsgaard and K. T. Herbst. U.S.P. 1,423,233, 18.7.22. Appl., 14.9.21.

A perchlorate of a methyl-substituted ammonium compound is used as an explosive.—H. C. R.

Pyrotechnic composition. W. T. Scheele, Assr. to Government of the United States. U.S.P. 1,423,264, 18.7.22. Appl., 9.12.19.

The composition comprises hexamethylenetetramine and strontium nitrate in the form of a double salt, to which a finely powdered metal is added.
—H. C. R.

XXIII.—ANALYSIS.

Refractive indices of liquids; Simple instrument for taking ——. R. Fouracre. Brit. Pharm. Conf., July. Pharm. J., 1922, **109**, 88—89.

A parallel beam of light from a small electric lamp placed at the focus of a convex lens, is projected through another convex lens laid on a glass plate with the liquid to be examined between the two, and brought to a focus on a plane surface. The focal length of the lens used in the combination divided by the distance between the surface of the liquid and the image, and the result subtracted from 2, will give the refractive index of the liquid.
—G. F. M.

Diphenylguanidine; Symmetrical —— *as a standard in acidimetry and alkalimetry.* C. A. Carlton. J. Amer. Chem. Soc., 1922, **44**, 1469—1474.

Diphenylguanidine is the only basic substance, proposed as a standard, which fulfils all the requirements of an ideal standard. It can easily be purified by three recrystallisations of the crude material from toluene, it is stable in air, and soluble in alcohol. It may be titrated directly in cold solution with either an alcoholic or an aqueous solution of hydrochloric acid, using either bromophenol blue or methyl red as indicator. The results are comparable with those obtained with sodium carbonate or silver chloride, and diphenylguanidine is more convenient to use.—J. F. S.

Fluorine; Detection of ——. B. Fetkenheuer. Wiss. Veröffentl. Siemens-Konzern, 1922, **1**, [3], 177.

The substance to be tested for fluorine is heated with sand and a few c.c. of strong sulphuric acid to

90° C. in a test-tube. On shaking, the acid runs off the glass like water off an oily surface if fluorine is present. With 2 g. of substance 0·01% F is easily detected after heating for 1 minute. Fluorides which are only attacked with difficulty by sulphuric acid, *e.g.*, ignited aluminium fluoride, must first be fused with a little sodium carbonate and sand and the melt treated as above with sulphuric acid.—A. R. P.

Magnesium compound of 8-*hydroxyquinoline.* [*Detection of magnesium.*] C. T. Mörner. Pharm. Zentralh., 1922, **63**, 399—402.

Magnesium hydroxide in suspension, magnesia mixture, or magnesium salts in alkaline solution give a yellow microcrystalline precipitate with aqueous solutions of 8-hydroxyquinoline sulphate. The reaction is very sensitive for magnesium. The precipitate approximates to the composition $(C_9H_6NO)_2Mg,4H_2O$. (*Cf.* J.C.S., Sept.) —G. W. R.

Potash; Determination of small amounts of —— by the Lindo-Gladding method. W. Hazen. J. Assoc. Off. Agr. Chem., 1922, **5**, 456—460.

In the determination of potassium by the Lindo-Gladding method the use of 90% alcohol for washing gives better results than that of 80% alcohol, and when working with small amounts of potash and high accuracy is desired, it is advisable to use the stronger alcohol for washing after the ammonium chloride treatment as well as for the first washing. The lower results obtained by using the weaker alcohol do not appear to be due to the sodium salts which may be present, as has been suggested, as equally low results are obtained in the absence of sodium salts. As, however, it takes a longer time to wash out the ammonium salts with 90% alcohol, it is preferable to use 80% alcohol for the second washing in ordinary work with fertilisers, where the percentage error arising from this will not be very serious, as the samples generally contain relatively high amounts of potash.—G. F. M.

Sulphur; Rapid estimation of ——. L. Losana. Giorn. Chim. Ind. Appl., 1922, **4**, 297—299.

Application of the method previously described (J., 1922, 614 a) to the estimation of sulphur in pyrites, copper pyrites and other mineral sulphides, ultramarine, adulterated white lead, cement, various rocks, sulphates of copper, sodium, etc. shows that the method serves generally with inorganic sulphur compounds. With fuels such as petroleum, anthracite and coke, results are obtained agreeing perfectly with those furnished by Eschka's method, which takes a considerably longer time. With ichthyol, saccharin, ebonite, and rubber, the method also gives excellent results.—T. H. P.

Uranium; Electrometric titration of —— with potassium permanganate and potassium bichromate. D. T. Ewing and E. F. Eldridge. J. Amer. Chem. Soc., 1922, **44**, 1484—1489.

When solutions of uranyl sulphate, reduced with zinc, are titrated electrometrically with permanganate, or when solutions of uranium chlorides similarly reduced are titrated with bichromate, a change in the oxidation potential occurs when the trivalent uranium is all oxidised to quadrivalent uranium, and a second change occurs when the latter is all oxidised to the hexavalent condition. Thus the total amount of uranium may be calculated. A third change of potential is observed when iron is present, and this is the stage at which all the ferrous iron is oxidised to ferric iron. The determination is carried out with apparatus of the usual type except in the form of the titration vessel. Since it is necessary to prevent the free access of air, the titration cell is a glass vessel closed by a tightly fitting cover which has six holes bored through it. Through the holes pass a tube for leading in carbon dioxide, a platinum electrode, the connecting tube of a calomel electrode, a stirrer fitted with a mercury seal, the tip of a burette, and the mouth of a Jones "reductor." All the tubes are tightly fitted. The method of procedure is as follows: *Estimation of uranium with permanganate.* Ten c.c. of a solution of uranyl sulphate, containing about 0·013 g. U_3O_8 per c.c. is added to 40 c.c. of sulphuric acid *A* (2 c.c. of concentrated acid to 88 of water) and warmed to 80°—90° C. Carbon dioxide is passed through the titration cell to remove the air, and the uranium solution slowly passed through the Jones "reductor" into the cell, the "reductor" being finally rinsed with 50 c.c. of sulphuric acid *A*. At this stage the solution is brown in colour, has a volume of 100 c.c., and contains 2 c.c. of concentrated sulphuric acid. The stirrer is set in motion and the permanganate slowly added. The EMF rises slowly at first and then jumps to a steady value, which is the point where all the trivalent uranium has passed into the quadrivalent condition and the solution has become green. Continued addition of permanganate does not affect the EMF markedly until the second change point is reached, and here the EMF jumps rapidly. At this point the whole of the quadrivalent uranium has passed into the hexavalent condition. The volume of permanganate used between the first and second end points represents the theoretical amount of oxidising agent required to oxidise uranium from the quadrivalent to the hexavalent state. Hence from this quantity the total amount of uranium present, no matter what its state of oxidation provided that none is hexavalent, can be calculated. *Estimation of uranium and iron with permanganate.* The process is carried out as above, the first and second change points giving the amount of uranium. After the uranium has all been oxidised to the hexavalent condition the oxidation of the ferrous iron commences, and is complete when the third change point is observed. Hence the amount of permanganate required to carry the EMF from the second to the third change point is equivalent to the amount of iron present. *Estimation of uranium by bichromate.* The two change points observed have the same significance as in the other cases. All the methods yield excellent results. —J. F. S.

Carbon and hydrogen; Volumetric estimation of —— in organic compounds. J. Lindner. Ber., 1922, **55**, 2025—2031.

The substance is burnt in the usual manner and the products of its combustion are passed over a substance which by its hydrolysis gives hydrogen chloride, and thence into a known volume of standard barium hydroxide solution. This is titrated with $N/10$ hydrochloric acid in the presence of phenolphthalein; the carbon dioxide is removed subsequently after addition of an excess of hydrochloric acid and the resulting solution is again titrated with barium hydroxide. The most suitable substance for hydrolysis is chloronaphthyloxychlorophosphine, prepared by passing chlorine into molten naphthyldichlorophosphine.—H. W.

Micro incineration. A. Schoeller. Ber., 1922, **55**, 2191—2192.

The substance under investigation is spread evenly over a thin strip of glass (5—6 mm. wide), which is placed in a horizontal hard glass tube about 10 mm. in diam. and 12 cm. long. The tube is heated very gently until all volatile matter is expelled. The residue is allowed to cool and is subsequently heated rather more strongly in a current of moist oxygen; in most cases the carbon disappears rapidly without at any time glowing. With difficultly combustible substances it is advisable to interrupt the heating again. Too powerful ignition is to be avoided. The minutest trace of ash is readily visible under the microscope. The method is particularly suitable for the incineration of sections of plant tissue, since the original structure is better preserved than when they are heated over a free flame.—H. W.

Filtration of vegetable juices. G. André. Comptes rend., 1922, 175, 286—289.

The passage of the expressed juice of potatoes, clarified by centrifuging, through a collodion membrane impoverishes the liquid in nitrogen and phosphorus, the results in a typical instance showing a reduction from 0·385% to 0·167% of the former, and from 0·044% to 0·019% of the latter. The phosphorus traversing the membrane is practically all mineral phosphate. Coagulation of the juice at 100° C. produces a similar effect as far as the nitrogen is concerned, but the reduction of the phosphorus in solution is, in general, not nearly so great, 0·033% being non-coagulable in the juice above cited, against only 0·019% traversing the membrane. Instances were not lacking, however, where the fraction of the phosphorus traversing the collodion approached that remaining in the non-coagulable liquid.—G. F. M.

Patents.

Calorific value of fluids [gas]; Method of and apparatus for carrying on the combustion of proportioned quantities of fluid for the purpose of measuring the ——. Igranic Electric Co., Ltd. From Cutler-Hammer Mfg. Co. E.P. 182,573, 7.4.21.

In a gas calorimeter, "firing back" at the burner is prevented by mixing the combustible gas, prior to combustion, with less than the total requisite proportion of the other constituent of the combustible mixture and supplying the remainder at or near the point of combustion.—J. S. G. T.

Gases; Method of and apparatus for measuring the density of ——. G. König. E.P. 159,845, 5.3.21. Conv., 5.3.20.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Alexander. Separating liquids of different specific gravity. 22,172. Aug. 18.

Altenkirch, and Siemens-Schuckertwerke Ges. Refrigerating-apparatus of the absorption type. 22,571. Aug. 18.

Bloomfield, and Boake, Roberts and Co. Distilling and fractionating apparatus. 22,781. Aug. 22.

Broadbridge, Minerals Separation, Ltd., and Williams. Filtration and conveying of granular etc. material. 22,576. Aug. 18.

Burt, Boulton, and Haywood, Ltd., and China. Grinding-mills. 23,132. Aug. 25.

Collins. Mixing-machines. 23,181. Aug. 26.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. Manufacture of porous or absorbent material. 22,093. Aug. 14.

Dried Milk Dairy Products, Ltd., and Sierra. Separation of solids from gases. 22,748. Aug. 21.

Dried Milk Dairy Products, Ltd., and Gluckstein. Collection and separation of solids from gases. 22,749. Aug. 21.

Fowler. Grinding-mills. 22,332. Aug. 16.

Hurrell. Pressure filters. 22,261. Aug. 16.

Hurrell. Continuous pressure filter. 22,282. Aug. 16.

Kirchhoff & Co., and Oppen. 22,591. *See* XI.

Lambert. Mixing-machines. 23,056. Aug. 24.

Lawrence Patent Water Softener and Sterilizer Co., Ltd., and Warden-Stevens. Proportioning, mixing, and dividing liquids and dissolving solids etc. 23,213. Aug. 26.

Loke. Furnace linings, crucibles, etc. 22,519. Aug. 18.

Paterson. Apparatus for treating liquids by chemical reagents. 23,063. Aug. 24.

Pehrson. Rotary furnaces. 22,543. Aug. 18. (Sweden, 20.8.21.)

Richards and Sopwith. Refrigeration. 22,070. Aug. 14.

Shores, and United Alkali Co., Ltd. Manufacture of ice. 22,096. Aug. 14.

Stuart. Heat exchangers. 22,826. Aug. 22. (U.S., 22.8.21.)

Stuart. Filter screens. 22,827. Aug. 22. (U.S., 22.8.21.)

Thomas. Apparatus for mixing gases automatically. 23,110. Aug. 25.

Thomson. Disintegrating solids. 23,155. Aug. 25.

Tunnadine. Means for filtering liquids. 22,605. Aug. 19.

Yardley. Apparatus for purifying etc. air etc. 23,146. Aug. 25.

Complete Specifications Accepted.

4898 (1921). Barbet et Fils et Cie. Process and apparatus for continuous rectification of liquid air. (159,131.) Aug. 30.

10,024 (1921). Mather. Condensers, preheaters, heat-exchangers, and the like. (184,222.) Aug. 23.

10,889 (1921). Twigg. *See* VIII.

12,395 (1921). Schloemann and Dobbelstein. Process and apparatus for the conveyance of loose materials. (184,237.) Aug. 23.

12,524 (1921). Glossop, Bradley, and Willsdon. *See* III.

12,981 (1921). Pessi. Method of preventing incrustation in steam-boilers. (163,013.) Aug. 23.

13,379 (1921). Sturtevant Engineering Co., Ltd., and Powell. Treatment of material and substances ith jets of fluid. (184,557.) Aug. 30.

14,848 (1921). Burden. Machines or apparatus or reducing or disintegrating minerals and similar materials. (184,609.) Aug. 30.

18,336 (1921). Schull. Process and apparatus or purifying and condensing exhaust steam and or purifying the condensate. (184,342.) Aug. 23.

34,962 (1921). Von Wurstemberger. Prevention f selective corrosion in machines or apparatus of metallic parts made of copper and copper-containng alloys and subject to the corrosive action of water containing ions. (174,059.) Aug. 30.

17,391 (1922). Gardner. Mixing and/or disntegrating machines. (184,433.) Aug. 23.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION, HEATING; LIGHTING.

Applications.

Allan, Burmah Oil Co., Ltd., and Moore. 22,168. *See* XII.

Broadhead. Manufacture of combustible gases. 22,884. Aug. 22.

Burmah Oil Co., Ltd., and Moore. 22,167. *See* XII.

Burn. Gas-producers. 23,160. Aug. 25.

Davidson. Destructive distillation of coal etc. 22,198. Aug. 15.

Ges. für Kohlentechnik. 22,127. *See* VII.

Hudson and Hudson. Complete coal gasification plant. 22,475–6. Aug. 18.

Lelarge. Apparatus for separating coke etc. from ashes etc. 22,562. Aug. 18.

Leopold, and Meguin A.-G. Magnetic separating process for treatment of residues of fuel. 22,751. Aug. 21. (Ger., 21.8.21.)

Pautriero. Electric lamps. 22,839. Aug. 22.

Pedersen and Prass. Manufacture of electric-incandescent lamps. 22,456. Aug. 17.

Pickard. Production of combustible gases. 22,280. Aug. 16.

Poulson. 22,606. *See* XII.

Complete Specifications Accepted.

4996 (1921). Roberts. Process and apparatus for recovering by-products from distillate gases. (184,507.) Aug. 30.

7317 (1921). Withers (Deutsche Evaporator A.-G.). Method and means for utilising the heat contained in the fuel residues of furnaces. (184,211.) Aug. 23.

8636 (1921). Hird. Apparatus for the carbonisation of coal, shale, peat, lignite, and the like. (184,525.) Aug. 30.

12,406 (1921). Thompson (Ver. Glühlampen- und Elektrizitäts A.-G.). Sealing of leading-in wires for electric incandescent lamps and for similar purposes. (184,238.) Aug. 23.

12,700 (1921). Blyth. Process for the combustion of pulverised fuel. (184,250.) Aug. 23.

12,911 (1921). Jacobs. Drying of lignite, peat, turf, and the like. (163,719.) Aug. 23.

13,010 (1921). Patent Treuhand Ges. für Elektrische Glühlampen. *See* X.

13,277 (1921). Haddan (Torfverwertungsges. Pohl und von Dewitz). Process of drying and compressing raw peat and the like. (165,445.) Aug. 30.

13,278 (1921). Haddan (Torfverwertungsges. Pohl und von Dewitz). Process of dry distillation and coking of raw peat and the like. (169,952.) Aug. 30.

13,447 (1921). Dale. *See* XXIII.

13,514 (1921). Quarzlampen-Ges. Quartz mercury-vapour lamps. (165,081.) Aug. 23.

13,515 (1921). Dunstan. Refining of liquid hydrocarbons. (184,281.) Aug. 23.

14,144 (1921). Oberlander and Le Maréchal. Incandescent electric lamps and the like. (184,291.) Aug. 23.

14,188 (1921). Plauson's (Parent Co.), Ltd. (Plauson). *See* XX.

14,781 (1921). Hawes. Alcohol fuel. (184,607.) Aug. 30.

14,918 (1921). Woosnam. Electric glow lamps. (184,302.) Aug. 23.

15,248 (1921). Courbeyeur and Clabaut. Apparatus for generating combustion-products under pressure. (164,693.) Aug. 30.

16,469 (1921). Climie. Gas-producers. (184,323.) Aug. 23.

29,429 (1921). Ges. für Drähtlose Telegraphie. *See* XXIII.

34,948 (1921). Schulz. Regenerators for heating air or gas for combustion. (184,744.) Aug. 30.

2401 (1922). British Thomson-Houston Co., Ltd. (General Electric Co.). Electric incandescent lamps. (184,748.) Aug. 30.

15,444 (1921). Dingler'sche Maschinenfabrik A.-G. Process for pre-heating blast-furnace and like gases in dry-gas purifying-plants. (182,102.) Aug. 30.

III.—TAR AND TAR PRODUCTS.

Complete Specifications Accepted.

12,524 (1921). Glossop, Bradley, and Willsdon. Process and apparatus for distilling tar and other liquids. (184,242.) Aug. 23.

13,515 (1921). Dunstan. *See* II.

15,726 and 34,279 (1921). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., Morgan, and Rider. Distillation of tar. (184,624.) Aug. 30.

IV.—COLOURING MATTERS AND DYES.

Applications.

Bailey. 22,979. *See* VI.

Sokal (Kalle und Co., A.-G.). Process for producing vat colouring-matters. 23,033. Aug. 24.

Complete Specification Accepted.

8254 (1921). Farbw. vorm. Meister, Lucius, und Brüning. *See* VI.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Cope (Pfarrius). Method of treating fibrous material. 22,067. Aug. 14.

Dawber. Utilisation of waste refuse from paper-making. 22,151. Aug. 15.

Perry. 22,211. *See* XVIII.

Plauson's (Parent Co.), Ltd. (Plauson). Treatment of cellulose etc. 22,687. Aug. 21.

Complete Specifications Accepted.

3742 (1921). Duclaux. Process for utilising cellulose esters. (184,197.) Aug. 23.

7570 (1921). Little, Inc. Process of preparing cellulose butyrate. (167,143.) Aug. 23.

10,615 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture and treatment of viscose. (184,533.) Aug. 30.

13,592 (1921). Schülke. Method of and apparatus for producing artificial threads, more particularly multiple-filament threads, from cellulose solution. (163,312.) Aug. 23.

14,852 (1921). Budde. Manufacture of hydra-oxy-cellulose and a xanthogenated compound obtained therefrom and a solid compact material obtained by coagulation of the latter. (184,610.) Aug. 30.

19,531 (1921). Dreyfus. Manufacture of solutions, compositions, preparations or articles made with cellulose derivatives. (184,671.) Aug. 30.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Bailey. Apparatus for ascertaining fastness of dyes to milling etc. and/or effect of such operations on fabrics. 22,979. Aug. 24.

Lord. Sizing, dyeing, bleaching, etc. machines for hanks. 22,923. Aug. 23.

Wolfenden. Dyeing-apparatus. 22,978. Aug. 24.

Complete Specifications Accepted.

20,033 (1921). Burton and Glover. *See* XV.

8254 (1922.) Farbw. vorm. Meister, Lucius, und Brüning. Manufacture of stable dry and soluble vat-preparations for dyeing. (177,526.) Aug. 30.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Casale. Apparatus for catalytic synthesis of ammonia. 23,072. Aug. 24.

Clayton, and Salt Union, Ltd. Manufacture of hydrogen peroxide. 22,045. Aug. 14.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. Manufacture of base-exchanging compounds. 22,091–2. Aug. 14.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. 22,095. *See* XIX.

Douglas. Manufacture of sulphate of ammonia. 22,347. Aug. 17.

Fairlie. Acid plant equipment. 23,083. Aug. 25.

Gardner and Taverner. Extraction of iron and titanium compounds from titanium ores. 22,728. Aug. 21.

Ges. für Kohlentechnik. Process of removing sulphuretted hydrogen from gases. 22,127. Aug. 14. (Ger., 20.9.21.)

Reynard, Tapping, and Thornley. Process for utilisation of seaweed. 22,644. Aug. 19.

Sim and Smith. Manufacture of lead carbonate. 22,455. Aug. 17.

Soc. Gamichon Frères. Process of manufacture of lead oxides. 22,103. Aug. 14. (Fr., 19.8.21.)

Complete Specifications Accepted.

4672 (1921). Williams. Process of manufacturing soluble phosphates. (184,206.) Aug. 23.

4898 (1921). Barbet et Fils et Cie. *See* I.

9617 (1921). Dossett. Process of and apparatus for crystallising copper sulphate. (184,527.) Aug. 30.

12,573 (1921). Chem. Fabr. Griesheim-Elektron, and Suchy. Process for the electrolytic production of potassium bicarbonate from potassium chloride solutions. (184,244.) Aug. 23.

13,290 (1921). Minami Manshu Tetsudo Kabushiki Kaisha. Process of manufacturing anhydrous chlorides of alkaline earth metals. (163,304.) Aug. 23.

22,404 (1921). Von Faber. Process for recovering iodine. (168,324.) Aug. 23.

VIII.—GLASS; CERAMICS.

Applications.

Grace. Means for separating fine micaceous and siliceous particles from china clay. 22,444. Aug. 17.

King. Production of colour effects in glass, crystal, etc. 22,514. Aug. 18.

Loke. 22,519. *See* I.

Mellersh-Jackson (Libbey-Owens Sheet Glass Co.). Apparatus for drawing sheet glass. 23,074. Aug. 24.

Mellor. 22,149. *See* X.

Spangenberg. Abrassive and cleansing etc. material, and method of producing same. 22,436. Aug. 17.

Unwin. Enamel kilns etc. 22,904. Aug. 23.

Complete Specifications Accepted.

10,889 (1921). Twigg. Method and means of utilising waste heat for effecting the drying of bricks or such like. (184,540.) Aug. 30.

13,172 (1921). Feldenheimer and Plowman. Treatment of clay. (184,271.) Aug. 23.

24,874 (1921). Bailey. Kilns for firing pottery and other ware. (184,716.) Aug. 30.

26,797 (1921). Scheid, and Schomburg und Söhne A.-G. Manufacture of pottery particularly adapted to electric insulators. (184,725.) Aug. 30.

IX.—BUILDING MATERIALS.

Applications.

Andrews. Manufacture of Portland cement. 22,982. Aug. 24.

Newton. Cement or adhesive composition. 22,341. Aug. 17.

Complete Specification Accepted.

13,504 (1921). Hildyard. Production of imitation wood. (184,565.) Aug. 30.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Anderson and Thornhill. Process for production of sponge iron etc. 22,059—60. Aug. 14.

Barter Trading Corp., Ltd., and Watson. Ferro-silicon blocks. 22,409. Aug. 17.

Bengough and Stuart. Method of preserving aluminium and its alloys from corrosion. 22,625. Aug. 19.

British Thomson-Houston Co., Ltd. (General Electric Co.). Composite metal articles, and methods of manufacturing same. 22,638. Aug. 19.

Davies and Thompson. Magnetic separators. 22,620. Aug. 19.

Drysdale and Evans. Protection of metals from corrosion. 22,353. Aug. 17.

Grogan and Rosenhain. Process of improving commercial aluminium. 22,454. Aug. 17.

Leggo. Roasting-furnaces. 22,460. Aug. 17.

Lloyd. Furnace for manufacture of liquid steel. 23,199. Aug. 26.

Mathesius and Mathesius. Process for producing lead alloys containing strontium. 23,048. Aug. 24. (Ger., 24.8.21.)

Mellor. Manufacture of clay crucibles, stoppers, etc. for steel melting etc. 22,149. Aug. 15.

Mond (International Process and Engineering Corp.). Chloridising roasting of ores etc. 22,243. Aug. 15.

Nobel. Manufacture of ferro-chromium. 22,951. Aug. 23.

Nobel. Production of ferro alloys. 22,952. Aug. 23.

Poulson. Blast furnaces. 22,352. Aug. 17.

Complete Specifications Accepted.

4782 (1921). Mellersh-Jackson (Soc. Metalurgica Chilena "Cuprum"). Process for treating ores. (184,501.) Aug. 30.

4892 (1921). Marks (Valley Mould and Iron Corp.). Method of casting steel-ingots and mould for use therewith. (184,505.) Aug. 30.

7797 (1921). Malmberg and Holström. Apparatus for the determination of the percentage of carbon in iron and steel. (184,215.) Aug. 23.

12,793 (1921). Façoneisen-Walzwerk L. Mannstaedt und Co. A.-G., and Bansen. Hearth-smelting or heating furnaces. (184,252.) Aug. 23.

13,010 (1921). Patent Treuhand Ges. für Elektrische Glühlampen. Manufacture of drawn tungsten wires. (163,014.) Aug. 23.

13,622 (1921). Soc. d'Electro-Chimie et d'Electro-Metallurgie. Process for obtaining metallic electrolytic deposits easily detachable from the cathode. (165,082.) Aug. 30.

15,815 (1921). Elmore, and Chemical and Metallurgical Corp., Ltd. Treatment of argentiferous lead-zinc sulphide ores. (184,628.) Aug. 30.

16,871 (1921). Harris. Apparatus for refining metals. (184,639.) Aug. 30.

26,787 (1921). Bardt. Process for dissolving-out or recovering the metal constituents of metalliferous materials. (184,402.) Aug. 23.

34,962 (1921). Von Wurstemberger. *See* I.

15,444 (1922). Dingler'sche Maschinenfabr. A.-G. *See* II.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. Electric battery. 22,094. Aug. 14.

Hartman. Ozone-generator. 22,104. Aug. 14.

Kirchhoff und Co., and Oppen. Electric gas-purifiers. 22,591. Aug. 19. (Belg., 16.9.21.)

Nickum. Electrolytic apparatus, and method of depolarising same. 22,859. Aug. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

7973 (1921). Elektrizitäts A.-G. vorm. Schuckert und Co. Electrolytic cell. (165,071.) Aug. 30.

12,573 (1921). Chem. Fabr. Griesheim-Elektron, and Suchy. *See* VII.

13,622 (1921). Soc. d'Electro-Chimie et d'Electro-Metallurgie. *See* X.

17,765 (1921). Smith. Secondary cells, or batteries for electricity storage. (184,649.) Aug. 30.

17,784 (1921). De Vos. Electric accumulators. (184,336.) Aug. 23.

18,589 (1921). Dinin. Electric accumulators. (184,658.) Aug. 30.

26,797 (1921). Scheid, and Schomberg und Söhne A.-G. *See* VIII.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Allan, Burmah Oil Co., Ltd., and Moore. Stoves for manufacture of waxes. 22,168. Aug. 15.

Burmah Oil Co., Ltd., and Moore. Apparatus for cooling oil etc. 22,167. Aug. 15.

North. 22,242. *See* XIX.

Poulson. Process of clarifying oils. 22,606. Aug. 19.

Spangenberg. 22,436. *See* VIII.

Villain. Manufacture of transparent soaps etc. 22,833. Aug. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

10,616 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of compositions of oils or other organic substances. (184,534.) Aug. 30.

10,940 (1921). Eppenberger. Process for rendering fat-containing granular products impalpable. (176,305.) Aug. 30.

12,628 (1921). Chamberlin. Detergent with disinfecting properties. (184,248.) Aug. 23.

15,448 (1921). Mellersh-Jackson (Murray Co.). Art of forming and wrapping oil-bearing material prior to the expression of oil therefrom. (184,621.) Aug. 30.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Consortium für Elektrochemische Industrie Ges. Manufacture of resins resembling shellac. 22,222. Aug. 15. (Ger., 27.8.21.)

Freegard. Composition of matter for removal of paint etc. 22,554. Aug. 18.

Gardner. Paints etc. 22,727. Aug. 21.

Ponter. Preparation for removing paint etc. 23,153. Aug. 25.

Sim and Smith. 22,455. *See* VII.

Soc. Gamichon Frères. 22,103. *See* VII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Gould. Rubber composition for roads etc. 22,550. Aug. 18.

Mead. India-rubber manufacture. 22,513. Aug. 18.

Warmund. Process for production of compound for sealing pneumatic etc. tyres and for preserving rubber. 22,822. Aug. 22. (Ger., 22.8.21.)

COMPLETE SPECIFICATIONS ACCEPTED.

13,871 (1921). Britton, and Griffiths Bros. and Co., London, Ltd. Preparation of rubberised fabric and rubber goods. (184,578.) Aug. 30.

XV.—LEATHER; BONE; HORN; GLUE.

COMPLETE SPECIFICATIONS ACCEPTED.

13,500 (1921). Devonshire and Foord. Composition for use in the manufacture of buttons and other articles. (184,563.) Aug. 30.

20,033 (1921). Burton and Glover. Preparation of a tanning-agent for the chrome tannage or dyeing of leather. (184,360.) Aug. 23.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Beer. 22,438. *See* XIX.

Gradl. Manufacture of artificial manures. 22.217, Aug. 15. 22,888, Aug. 22. 23,067, Aug. 24. (Ger., 15.8, 3.9, and 22.11.21.)

COMPLETE SPECIFICATION ACCEPTED.

4672. Williams. *See* VII.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Perry. 22,211. *See* XVIII.

Rigby. Utilisation of exhausted sugar-beet slices, waste brewery grains, etc. 22,179–80. Aug. 15.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Johansson. Process for denaturing alcohol etc. 23,143. Aug. 25. (Sweden, 26.8.21.)

Perry. Process for treating cellulose etc. for obtaining fermentable sugars etc. 22,211. Aug. 15.

Rigby. 22,179–80. *See* XVII.

Complete Specifications Accepted.

14,781 (1921). Hawes. *See* II.

22,079 (1921). Vydra. Process of producing a malt preparation for brewing purposes. (184,381.) Aug. 23.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Abbott, Cork, McNeill, Macredie, and Remus. Process for preparation of meat powders. 22,459. Aug. 17. (New Zealand, 27.8.21.)

Adeane, Harding, and Whetham. Treatment of whey etc. 23,121. 23,123. Aug. 25.

Adeans, Hopkins, Stewart, and Whetham. Treatment of whey etc. 23,127. Aug. 25.

Beer. Fungicides for plants or seeds. 22,438. Aug. 17.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. 22,091–2. *See* VII.

Crosfield and Sons, Ltd., Hilditch, and Wheaton. Process of regenerating base-exchanging compounds after use. 22,095. Aug. 14.

Enefer. Meal for bread-making. 22,807. Aug. 22.

Lawrence Patent Water Softener and Sterilizer Co., Ltd., and Warden-Stevens. 23,213. *See* I.

Leo. Food products, and method of making same. 22,852. Aug. 22.

Luft. Food products, and process of preparing same. 22,246. Aug. 15.

Luft. Food products. 22,435. Aug. 17.

Marks (Wayne Tank and Pump Co.). Continuous softening of water. 22,320. Aug. 16.

Melhuish. Manufacture of milk. 22,693. Aug. 21.

North. Process of producing milk artificially. 22,240. Aug. 15.

North. Process of making butter from artificial cream. 22,241. Aug. 15.

North. Process of obtaining oil from milk. 22,242. Aug. 15.

O'Connor and O'Connor. Manufacture of bread etc. 22,349. Aug. 17.

O'Connor and O'Connor. Manufacture of butter etc. 22,350. Aug. 17.

Paterson. 23,063. *See* I.

Roggers. Treatment of sewage etc. 22,115. Aug. 14.

Yardley. 23,146. *See* I.

Complete Specifications Accepted.

4208 (1921). International Dry Milk Co., and Dick. Dehydrated milk. (184,203.) Aug. 23.

10,940 (1921). Eppenberger. *See* XII.

12,628 (1921). Chamberlin. *See* XII.

29,429 (1921). Ges. für Drähtlose Telegraphie. *See* XXIII.

34,124 (1921). Imhoff. Treatment of sewage in undrained settling basins. (184,742.) Aug. 30.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Application.

Etabl. Poulenc Frères. Process for preparation of aminophenylarsinic acids. 22,440. Aug. 17. (Fr., 7.9.21.)

Complete Specifications Accepted.

10,616 (1921). Plauson's (Parent Co.), Ltd. (Plauson). *See* XII.

13,664 (1921). Galbraith, Shannan, Adam, and Siderfin. Manufacture of amines from phenolic compounds. (184,284.) Aug. 23.

14,049 (1921). Soc. Anon de Prod. Chim. Etabl. Maletra. Process for the production of acetaldehyde from acetylene. (165,085.) Aug. 30.

14,188 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of ichthyol oil and ichthyol preparations and the like. (184,292.) Aug. 23.

15,730 (1921). Imray (Soc. of Chem. Ind. in Basle). Manufacture of dialkylamides of nicotinic acid. (184,625.) Aug. 30.

15,732 (1921). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of oxalic acid. (184,627.) Aug. 30.

34,532 (1921). Lilienfeld. Manufacture of a remedy for malignant tumor. (173,507.) Aug. 23.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Dunning and Kelley. Motion-picture films. 22,711. Aug. 21.

Lucoque, Pilgrim, and Rudkin. Photographic films. 22,388. Aug. 17.

Lucoque, Pilgrim, and Rudkin. Photographic developing-solutions. 22,389. Aug. 17.

Lucoque, Pilgrim, and Rudkin. Production of direct photographic positives. 22,390. Aug. 17.

Complete Specifications Accepted.

3233 (1921). Ott. Process for coating the surface of cinematograph films. (184,495.) Aug. 30.

4437 (1921). Stewart and Killick. Method for producing kinematograph pictures in natural colours. (184,205.) Aug. 23.

6902 (1921). Luboshey. Sensitive film-supports for X-ray photography. (184,519.) Aug. 30.

10,954 (1921). Lepine. Picture films. (184,541.) Aug. 30.

XXII.—EXPLOSIVES; MATCHES.

Application.

Nobel Industries, Ltd., and Weir. Manufacture of detonators. 22,214. Aug. 15.

XXIII.—ANALYSIS.

Complete Specifications Accepted.

7797 (1921). Malmberg and Holström. *See* X.

13,447 (1921). Dale. Apparatus for the analysis and recording of gases. (184,279.) Aug. 23.

29,429 (1921). Ges. für Drähtlose Telegraphie. Means for indicating the presence of noxious gases such as fire-damp. (171,988.) Aug. 30.

I.—GENERAL; PLANT; MACHINERY.

Steam-pipe coverings; [Determination of] efficiency of —— at high temperatures. C. Jakeman. Engineering, 1922, 114, 155.

The covering to be tested is put on a steel pipe 4 in. internal diameter, the pipe ends being closed with blind flanges. Correction for loss by radiation from the blank ends is obtained by dividing the experimental pipe into two unequal lengths, 2 ft. and $13\frac{3}{4}$ ft., so that the loss is eliminated by difference; the difference between the amounts of heat lost by the two lengths corresponds to the heat lost in a pipe of differential length, $11\frac{3}{4}$ ft. An electric heater in which the wires are arranged in six concentric rings, each ring being controlled by a separate switch, runs through the interior of the pipe. When all wires are used it is possible to raise the bare pipe to 1000° F. (about 540° C.). A pipe fitted with a good covering requires from $\frac{1}{8}$ to $\frac{1}{15}$ of the heat energy required for the bare pipe. The apparatus and method of calibration are described in detail.—J. B. F.

Adsorption: its bearing on catalysis. M. Guichard. Bull. Soc. Chim., 1922, 33, 647—653.

The adsorption of a vapour by a catalyst is conditioned by the equilibrium pressure and temperature at which the action takes place and is reversible. On the other hand, increase in temperature of preparation or in duration of preliminary heating of the catalyst decreases the quantity adsorbed and the action is, in this case, irreversible. These conclusions are drawn from a study of the adsorption of water vapour by precipitated silica, quartz sand, and reduced nickel, and of iodine vapour by some natural silicates, alumina, and glucina. The author maintains that the preliminary heating of the catalyst results in diminution of active surface and cites facts which tend to support this view.—H. J. E.

Patents.

Separating suspended particles from electrically insulating fluids, especially gases; Method and device for ——. The Lodge Fume Co., Ltd. From E. Möller. E.P. 183,768, 16.11.21.

Insulating fluids, more especially gases, containing fine suspended particles are submitted to the action of a single- or multi-stage bilateral electric field prior to treatment by a unilateral electric discharge in accordance with E.P. 17,840 of 1912 (F.P. 449,337; J., 1913, 495), and E.P. 19,733 of 1913. The finer particles are thereby more readily flocculated, and, if desired, the effect is increased by the use of a number of flocculation chambers arranged in series and not provided with electrodes.
—J. S. G. T.

Distilling column. F. E. Lichtenthaeler, Assr. to W. E. Lummus Co. U.S.P. 1,424,173, 1.8.22. Appl., 8.5.18.

The column is divided into compartments by transverse partitions. Means are provided for supporting one of the partitions and for supporting the other partitions from this one.—H. H.

Precipitation of solid or liquid suspended matter from gases by high-tension electricity; Process of ——. Metallbank u. Metallurgische Ges. A.-G. G.P. 350,259, 10.9.20. Addn. to 348,377.

In an installation such as that described in the previous patent (J., 1922, 491 a) the discharge electrodes are composed of non-conducting material or are coated with non-conducting material. Thus filaments or rods of quartz, glass, porcelain, or similar acid-resisting material may be employed. The device is particularly suitable for use where acids, *e.g.*, hydrochloric acid, are precipitated from the gas.—J. S. G. T.

Stable foam for preventing the evaporation of stored liquids. J. M. Jennings, Assr. to Standard Oil Co. U.S.P. 1,423,719–21, 25.7.22. Appl., (a) 22.11.20, (b) 24.5.21, (c) 26.10.21.

The foams are formed from (a) an aqueous solution containing 25% of glue, 10% of glycerin, 2% of ferrous sulphate, and a minute proportion of preservative; (b) a liquid consisting of less than 15% of water, glycerin, and a body-forming material; (c) a liquid containing 40—81% of glucose, 6—12% of water, 5—10% of glue, and a small proportion of a setting agent. (*Cf.* U.S.P. 1,415,351–2; J., 1922, 491 a.)—T. A. S.

Evaporator. R. Mellor, Assr. to Kestner Evaporator Co. U.S.P. 1,424,254, 1.8.22. Appl., 9.8.20.

A counter-current evaporator is formed of a vertical series of horizontal liquor tubes each provided with a heating jacket. Heating vapour flows through the series of jackets from an inlet on the uppermost jacket to an outlet for vapour and condensed liquid on the lowermost jacket. Trapped bypass connexions intercept condensed liquid at intervals and direct it to the outlet.—H. H.

Recovery of solid matter from liquids by evaporation; Process of and apparatus for ——. G. A. Krause u. Co. A.-G. G.P. (a) 347,073, 1.4.17, (b) 349,183, 5.1.18. (b) Addn. to 347,138.

(a) A vertical axial tube is supported upon the floor of a vertical hollow cylinder serving as evaporation vessel. The tube, which extends some distance within the cylinder, is provided with a number of horizontal openings in its circumference at one or more transverse sections of the tube and at the same height as corresponding horizontal openings in the cylinder. Above the openings, within the chamber, is a high-speed centrifuge which discharges atomised liquid into the chamber, this liquid then falling through a gaseous evaporating medium which passes practically horizontally between the respective openings in the tube and chamber. (b) In a process carried out in accordance with G.P. 347,138 (J., 1922, 316 a), in place of openings in the wall or floor of the evaporating chamber, a disc is mounted in the chamber so that there is an annular space between the edge of the disc and the casing. The stream of evaporating medium flows between the annular opening and the central opening provided for the supply of air.—J. S. G. T.

[Filter press sack] fabrics; Process of producing a repair in ——. A. O. Austin, Assr. to The Ohio Brass Co. U.S.P. 1,424,332, 1.8.22. Appl., 12.5.20.

Vulcanisable material is inserted in the portion of the fabric to be repaired, and is cured to cause it to adhere to the fabric and form a continuation thereof.—H. H.

Extracting apparatus; Rotary ——. J. W. Bodman, Assr. to W. Garrigue and Co. U.S.P. 1,424,335, 1.8.22. Appl., 13.1.21.

A horizontal jacketed rotary drum is provided at one end with a head enclosing a pocket connected by a pipe with the jacket. A valve at the inner side of the head is formed by a rotary member and a stationary member, and is provided with an interior space. Within the drum are secured spaced steam-delivery pipes connected with the valve so that they open into the valve space only when they occupy the lower portion of the drum during the rotation. A pipe leads axially through the outer portion of the head into the pocket, and a pipe of smaller diameter extends through this pipe into the valve space.—H. H.

Fractionation of volatile, and more especially easily volatile liquid mixtures; Process of ——. "Metan" Spolka z ograniczona odp. G.P. 351,082, 13.6.18. Conv., 27.3.17.

The mixture is supplied continuously under pressure to the top of a vertical dephlegmator, and the several fractions are withdrawn from the column at various heights according to the respective boiling points of the fractions. Owing to the higher boiling points due to the pressure in the column, a better separation of the several fractions is obtained than hitherto.—J. S. G. T.

Drying coal or other material; Apparatus for ——. T. A. Goskar. U.S.P. 1,424,565, 1.8.22. Appl., 29.10.21.

See E.P. 175,674 of 1920; J., 1922, 282 A.

Liquors; Method of evaporating ——. E. Josse and W. Gensecke. U.S.P. 1,425,020, 8.8.22. Appl., 27.4.20.

See E.P. 138,871 of 1920; J., 1921, 455 A.

Air pumps; Mercury vapour ejector ——. A.-G. Brown, Boveri, & Co. E.P. 173,500, 19.12.21. Conv., 31.12.20. Addn. to 165,400.

Air filters; Filter bag cleaning device for ——. W. F. L. Beth. E.P. 175,281, 9.2.22. Conv., 12.2.21. Addn. to 132,513.

Grinding mills [; Means for exerting elastic pressure on rollers in ——]. C. F. Leubli. E.P. 183,215, 14.4.21.

Gas and air valves [of gas-heated furnaces] and the like; Means for actuating ——. South Metropolitan Gas Co., D. Chandler, and J. J. Cooke. E.P. 183,862, 15.4.21.

Solids of different specific gravities; Means for separating ——. J. A. Fletcher. E.P. 184,049, 26.7.21.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal seams; Method of representing the structure of ——, *and the proportion and properties of the four constituents (vitrain, clarain, durain, and fusain) contained in certain seams.* F. S. Sinnatt. Trans. Inst. Min. Eng., 1922, 63, 307—317.

A method of estimating the percentages of the various constituents in a seam is described. These percentages were, for Arley coal, vitrain 14·6%, clarain 65·9%, durain 18·1%, and fusain 1·4%; for the Queen Mine, vitrain 1·3%, clarain 98·7%, durain nil, and fusain nil; for the Wigan Yard, vitrain 25·1%, clarain 51·9%, durain 20·2%, and fusain 1·0%, with 1·8% of foreign matter. The lowest proportion of durain (5·6%) occurs in the Trencherbone Bottoms, and the highest (35·5%) in the Trencherbone Tops. The fusain content ranges from nil in the Queen Mine to 2·0% in the Trencherbone Bottoms, whilst the clarain varies between 51·9% in the Wigan Yard to 98·7% in the Queen Mine. The analysis of any particular constituent is by no means constant when determined on samples from different seams. Vitrain apparently contains the highest percentage of moisture and the lowest percentage of ash; clarain evolves the highest percentage of volatile matter less moisture, and contains only a slightly higher percentage of ash than vitrain. Durain contains the lowest percentage of moisture and the greatest percentage of ash; the volatile matter evolved is less than that from either vitrain or clarain, and the percentage of ash is not so high as that found by Wheeler and Tideswell for the Hamstead Thick Seam. Fusain contains a high percentage of ash and a considerably lower percentage of volatile matter. The agglutinating values of the constituents, determined with electrode carbon of 60—90 mesh (I.M.M. standard sieves) were as follows:—Arley coal: coal 15, vitrain 9, clarain 17, durain 6, fusain nil; Wigan Five Feet: coal 4, vitrain 3, clarain 7, durain 5, fusain nil. Contrary to the observation made by Lessing on the Hamstead Thick Seam, the durain possesses marked caking properties, and in the case of the Wigan Five Feet Seam the agglutinating power of the durain is higher than that of the vitrain.—A. G.

Volatile matter in coal; Determination of the ——. E. St.-Claire Deville. Soc. Tech. Ind. du Gaz en France, June, 1922. Gas World, 1922, 77, 112.

The sample of coal, 2·5 g., is placed in a thick platinum crucible with an ovoid bottom and covered with a lid provided with a chimney of 5 mm. bore. The crucible is placed over a Méker burner in a small furnace the effect of which is to eliminate errors due to the different amounts of heat radiated from different crucibles. The crucible is heated gently for about 2 mins. until the flame at the tip of the chimney become non-luminous, then a perforated lid is placed on the furnace, and the temperature is raised for about 1 min. until the hydrogen flame dies down into the chimney. The crucible is removed to an iron frame and, when cold, the coke is taken out and weighed, the deposit upon the crucible lid being discarded.
—H. Hg.

Coal ash; Recovery of combustible material from ——. H. Nitzsche. Z. angew. Chem., 1922, 35, 458—460.

A description of the Krupp magnetic process for the recovery of combustible material from coal ash is given. Ash is fed on to the surface of a brass drum rotating about a horizontal axis and is there submitted to the action of a stationary magnetic field, the strength of which increases from the top of the cylinder to where the surface of the cylinder becomes vertical, thereafter decreasing to its least value in the lower quadrant of the cylinder. Particles of clinker, owing to their content of iron oxides, formed during the combustion of the original coal, are retained for a longer period on the drum than the non-magnetic combustible constituents of the ash. The power necessary varies from 0·6 to 2·4 kw.h. per ton of ash treated. Particulars are given of tests carried out with various samples of ash.
—J. S. G. T.

Gas-producers; Contribution to the theory of —— *and its application to blast-furnace practice.* A. Korevaar. Chim. et Ind., 1922, 8, 12—25.

The state of equilibrium in a gas-producer in full working order, *i.e.*, its temperature, and the composition and temperature of the issuing gases, is governed by its dimensions, the heat-insulating properties of its walls, the porosity, size, and activity of the fuel with which it is charged, and the velocity and temperature of, and proportion of oxygen and water vapour in, the current of air through it. A series of equations connecting these variables and the volume of the zone of combustion in an ideal gas-producer is developed, and it is shown that for a minimum zone of complete combustion, *i.e.*, to carbon dioxide, there is a definite critical value for the velocity of the air in order to maintain the maximum temperature in the zone. If the air is preheated its critical velocity is increased with a corresponding increase in the maximum temperature and decrease in the size of the zone of complete combustion. The more finely divided, more porous, and more "active" the carbon, the higher is the maximum temperature and the smaller the zone of complete combustion. The theory may be applied to the study of the economical working of blast furnaces by assuming that they are gas-producers working at a very high temperature and having a comparatively short zone of combustion in the neighbourhood of the tuyères. In this way it is shown that less fuel is needed the more "active" it is, and an explanation is possible of the fact that less fuel is required with a preheated than with a cold blast and with a slow air current than with a more rapid one, which simply serves to extend the zone of combustion.—A. R. P.

Gum- and resin-forming constituents in manufactured [carburetted] gas. R. L. Brown. Amer. Gas Assoc. "Monthly." Gas J., 1922, **159**, 327.

Resinous substances deposited in gas meters and service pipes are formed from unsaturated hydrocarbons in the gas; the presence of indene has been established in several samples of condensate examined. The gum-forming constituents are derived from the gas oil used and their occurrence depends upon the nature of the oil used and the methods of carburetting and purifying the gas.—H. Hg.

[Gas retorts;] Thin metal ascension pipes [for ——]. N. G. Caputi. Gas World, 1922, **77**, 105.

Ascension pipes were made of 12-gauge steel with welded joints; the cross-section of the pipes was 12 in. square between the bridge cap and the top of the retort, tapering to 8 in. square at the points between the mouthpieces and the buckstays, and to a 9 in. diam. spigot fitting the off-take of the mouthpiece. The bridge pipes were of the same material and general design. Due to the decreased thickness and increased area of the pipes there was more condensation within the pipes, and as the interior surfaces of the pipes were comparatively smooth there was less tendency for adherence of pitch deposits. Comparative tests showed that the average reduction of gas temperature within the steel pipes was 866° F. (480° C.) and within cast iron pipes 559° F. (310° C.).—H. Hg.

Blue water-gas in conjunction with coal gas; Plant for the manufacture of ——. J. Lowe. Gas J., 1922, **159**, 324—326.

The plant described in E.P. 149,928 (J., 1921, 207 A) has given the following working results:—16,290 cub. ft. of mixed gas containing 21·6% of water-gas and with a calorific value of 526 B.Th.U. per cub. ft. was made per ton of coal carbonised; the calorific value of the water-gas was 326 B.Th.U. per cub. ft., the blow gas contained 15·25% CO_2, 9·5% O_2, and 10·5% CO, and was used for heating the retorts; after allowing for the coke thus saved in the retort furnaces the efficiency of water-gas manufacture was 91·6%. In computing this efficiency figure allowance was made for the total heat of the steam used but not for the power required for blowing. Further thermal economy can be secured by passing the hot water-gas into vertical retorts used for coal gas manufacture. The period of blowing the producer is equal to the period of gas making, there being no loss due to over-blowing when the blow gas is used in the retort settings.—H. Hg.

Gas; New controller for quality of ——. A. Grebel. Soc. Tech. Ind. du Gaz en France, June, 1922. Gas World, 1922, **77**, 110—111.

Gas is supplied through a delicate pressure regulator to two Bunsen burners with adjustable primary air supplies. One burner is adjusted to give a sharp blue inner cone and the other to give a distinct luminous tip on the inner cone. The respective heights of the cones are noted when burning a standard coal gas. The heights of the cones increase or decrease as richer or poorer gas is supplied to the burners.—H. Hg.

Flame; Limits for the propagation of —— in vapour-air mixtures. Mixtures of air and one vapour at the ordinary temperature and pressure. A. G. White. Chem. Soc. Trans., 1922, **121**, 1244—1270.

Limits for upward, horizontal, and downward propagation of flame for vapours of twelve organic solvents (ether, alcohol, acetone, methyl ethyl ketone, benzene, toluene, methyl alcohol, ethyl acetate, acetaldehyde, ethyl nitrite, pyridine, carbon bisulphide) mixed with air were determined at room temperature (17° to 18°±3°) in tubes of internal diameter varying from 2·5 cm. to 7·5 cm. By varying the means of ignition the type of flame started was controlled, and the type of flame determined whether the flame was extinguished in or traversed certain vapour-air mixtures. The lower limits did not differ greatly with the direction of propagation; the upper limits for upward propagation were approximately one and a half times those for downward propagation, except for cases in which a "cool flame" appeared, in which case the ratio was much greater. Where a cool flame appears two ranges exist, one for the cool flame and one for the ordinary flame; the cool flame was not generally propagated downwards. With one exception (carbon bisulphide) the lower limit for propagation downwards was approximately proportional to the net calorific value of the vapour used; the upper limit was about three and a half times the lower. The velocity of the uniform movement of flame downwards was with one exception almost the same in the lower-limit mixtures. The ratio of the amount of available oxygen in the limit mixture for the combustion of the vapour to the amount required for the perfect combustion of one molecule of the vapour was nearly constant.—J. B. F.

Petroleum; Evaporation loss of —— in the Mid-Continent field. J. H. Wiggins. U.S. Bureau Mines Bull. 200, 1922, 115 pages.

Large losses are caused by evaporation during storage and handling of crude petroleum between the well and the refinery, but from two-thirds to four-fifths of this loss may be prevented by protecting the oil from free contact with air. Laboratory tests showed that gasoline present in light crude oil will evaporate about one-half as rapidly as when stored in the pure state after distillation. Blending the separated gasoline with a very heavy, viscous, high-flash oil will greatly reduce its rate of evaporation (by nearly two-thirds in the tests described), but blending with heavier gasoline or mineral seal oil does not materially reduce the rate of evaporation. Californian gasolines evaporate approximately twice as fast as those of the same gravity from the other U.S. oilfields.—H. M.

Oils; Determination of volatility of ——. A. R. Matthis. Bull. Fed. Ind. Chim. Belg., 1922, **1**, 397—405.

Some precautions that should be taken in measuring the evaporation of oils on being heated are frequently omitted and thus contradictory results are obtained. In addition to the quantity of oil used for the test and the temperature and duration of heating, the area of exposed surface and the projection of the vessel above the surface of the oil should be taken into account as these have a definite bearing on the rate of evaporation. The author, using vessels of different shape and different quantities of oil, shows that in extreme cases loss of weight may vary by 228% under otherwise identical conditions of heating. Details of a number of experiments are given and suggestions for the standardisation of the tests are put forward.—H. J. E.

PATENTS.

Concentration of coal. F. B. Jones, and Minerals Separation, Ltd. E.P. 183,504, 22.2.21.

COAL particles of linear dimensions between 0·1 and 0·5 in. are separated from impurities by film flotation or by sub-aeration, after the crude coal has been coated with oil or tar either by immersion or by agitation of an aqueous pulp of the coal with the oil. The quantity of oil required is 2 lb. per ton of crude coal. Suitable apparatus for the film flotation process is described in E.P. 25,204, 25,204 A, 25,858 and 29,374 of 1904 (J., 1906, 112; 1905, 1238, 893). Apparatus of the type described in E.P. 10,929 of 1910, 21,650 of 1913 or 10,312 of 1914 (J., 1911, 369; 1914, 1160; 1915, 620) may be used for the sub-aeration process, a trap being provided below the surface of the pulp to retain the large particles of coal discharged by the bubbles near the surface. The crude coal may also be treated by froth flotation in the apparatus described in E.P. 23,949 of 1910 (J., 1912, 31), in which case previous removal of the particles below 0·1 in. in size is unnecessary, so that fine coal is recovered in the froth and larger particles in the trap. Sea water may be used for the flotation of the larger particles.—H. Hg.

Peat and the like [e.g., sewage sludge]; Treatment of ——. Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and J. S. Morgan. E.P. 183,180, 12.3.21.

PEAT pulp or sewage sludge is pumped through two preheaters into an autoclave where, by means of a stirrer, it is exposed to the action of live steam. The pulp then flows over a weir in the autoclave and comes in contact with a rotary drum filter. Water and steam are withdrawn from the drum into a separator, whence the water is pumped through the first preheater and the steam is drawn through the second preheater. The partially dried material is removed from the drum by a scraper and passed into a bath of molten metal where it may be treated as described in E.P. 174,974 (J., 1922, 239 A). After the water content has been thus reduced to 15%, the material is forced through a pipe, having a choke to prevent loss of steam, into a bunker from which, in the case of peat, it is delivered to a briquetting machine. The vessel containing the molten metal is fitted with a steam valve loaded to ensure a temperature of 160° C. for the steam evolved from the material. This steam passes into the autoclave and dries the material on the filter; any excess which passes the loaded valve may be used for external purposes. The hot waste gas from the furnace surrounding the metal bath may be used to expel further moisture from the material leaving the metal bath.—H. Hg.

Peat for fuel or distillation purposes; Method of and apparatus for disintegrating, dehydrating, and otherwise treating ——. C. W. G. Clewlow. E.P. 183,566, 25.4.21.

PEAT pulp of the consistency of cream is heated to a temperature of about 300° F. (149° C.) under a pressure of 120—130 lb. per sq. in., and is then passed through a loaded relief valve so that the pressure is suddenly released. The outlet of the valve is connected with two pulp receivers and also, in an upward direction, with a chamber having a flue and a perforated conical base surrounded by a drainage space for the retention of any peat carried away by the steam.—H. Hg.

Peat; Process for drying ——. K. von Haken. G.P. 353,033, 2.10.19. Addn. to 341,179.

IN the treatment of peat either continuously or intermittently in several stages as described in the chief patent (J., 1922, 130 A), each drying space is connected with two heat accumulators to form one stage or unit, and the unsaturated mixture of air or gas and vapour is circulated between the more highly heated heat accumulator of that particular stage and the material in the drying space of the stage concerned. The circulation of the air or gas-vapour mixture is necessary to transfer the necessary quantity of heat to the material to be dried, without using excess of air.—A. G.

Gas retorts. H. Wood. E.P. 161,918, 15.4.21. Conv., 15.4.20.

A TAPERED vertical retort of rectangular cross-section is superimposed on a gas producer and surrounded by a series of superimposed heating chambers through which gas may pass in a zig-zag path. The bottom chamber communicates with the producer through a passage formed by a midfeather wall within the latter. Each chamber is provided with an external opening fitted with a gas-tight door for cleaning purposes. The blow gases from the producer may be passed through the chambers or, after the preliminary heating of the retort, heating gas may be supplied to burners projecting into the chambers, in which case the passage between the producer and the bottom chamber is closed by a damper.—H. Hg.

Gas producer and process. E. M. Braxton, Assr. to M. R. Spellman. U.S.P. 1,424,077, 25.7.22. Appl., 18.11.21.

A BED of lignite, conical on its underside, is rotated during gasification, and the gas is superheated at a point near the apex of the cone prior to being cleaned, cooled, and dried.—H. Hg.

Tar; Process for increasing the yield and quality of —— by carbonisation and gasification of solid fuels. Allgem. Elektrizitäts-Ges., and F. Münzinger. G.P. 349,685, 2.7.18.

HORIZONTAL cooling sections are built in the fuel chamber at one or several different heights so that the material to be treated can be cooled over the whole cross-sectional area of the chamber to a uniform degree in layers as desired. The cooling sections are so arranged that the gases from the lower strata can be cooled, either wholly or in part, before they reach the higher strata. The cooling sections regulate the temperature of the column of fuel continuously by transference of heat from the hot fuel to the cooling sections, and intermittently in that as a result of the cooling and/or partial withdrawal of gas entering a highly heated zone, little heat is carried upwards.—A. G.

Gas producer with means for separately producing and removing the distillation and producer gases. A. H. Nass. G.P. 350,220, 27.10.20.

FUEL is distilled in an annular chamber rotating around the outer wall of a gas producer provided with a rotating hearth. During the rotation of the chamber, the fuel is discharged into the producer through openings in the walls of the latter. Outlets are provided at the top of the chamber and the producer for drawing off the distillation and producer gases respectively.—L. A. C.

Coals and other tar-yielding materials; Coking of —— by means of the continuous action of hot combustible gases. H. Pape. G.P. 350,678, 28.11.19.

The gas to be used for coking is preheated first in a preheater, preferably of iron, heated externally, and then by mixing with the gases of combustion of a heating flame, burning in the stream of gas. —A. G.

Coke and gas; Process for preheating air and, if necessary, gas in chamber ovens with vertical heating conduits for the manufacture of ——. O. Wolff. G.P. 353,058, 13.7.21.

A portion of the waste heat is utilised to heat the waste heat conduit, lying between the waste gas collecting flues of the heating walls and the generator or recuperator-chamber, and the mains through which the gas and air pass to the burners in the same direction. In consequence of the avoidance of cooling losses the air and gas, or the air alone, are preheated to a higher degree than usual. —A. G.

Cooling, cleansing or scrubbing gases in connection with all types of gas producers; Apparatus for use in ——. O. B. Davies. E.P. 183,160, 19.1.21.

Gas passes downwards through an annular space formed by two concentric cylinders and then upwards through the inner cylinder. A helical plate is fixed within the annulus in order to increase the gas velocity and separate the impurities by centrifugal force. The impurities collect in a space below the open end of the inner cylinder and may be withdrawn by removing the base of the outer cylinder. A baffle having the form of propeller blades may be placed within this space. Removable filters may be placed within the inner cylinder. The outer cylinder is provided with cooling gills or flanges or is surrounded by a cooling jacket or by air cooling pipes.—H. Hg.

Hydrocarbons; Process of manufacturing liquid —— from fish oils. K. Kobayashi. E.P. 170,264, 22.4.21. Conv., 13.10.20.

Fish oils, *e.g.*, herring, salmon, or sardine oils, are decomposed by heating with Japanese acid clay to a temperature not lower than 500° C. Glycerin and fatty acids are formed and are subsequently broken down forming liquid hydrocarbons from which light oil, illuminating oil, and other fractions may be separated by distillation. (*Cf.* J., 1921, 250 A; 1922, 242 A.)—T. A. S.

Distillation of [hydrocarbon] oils. Trent Process Corp. Assees. of W. E. Trent. E.P. 171,075, 13.4.21. Conv., 4.11.20.

Oil is mixed with finely divided fuel of relatively high volatile content, *e.g.*, coal, anthracite, bituminous coal, or lignite, and distilled in a retort at a temperature approximating to 350° C. It is claimed that considerable cracking takes place, increasing the yield of gasoline and light oil from the oil. Any carbon residue is obtained as a dry dust. During distillation the mixture is agitated by rabbles. The mixture consists of 1 part of oil and 2 parts of coal by weight.—T. A. S.

Distillation of crude oil; Fractional ——. Apparatus for distilling crude oil and other liquids. P. Mather. E.P. 182,827—8, 11.1.21.

Crude oil, before delivery to a continuous still, is preheated both by the hot residue and the still vapours. The oil is sprayed or dropped on to coils containing the residues or vapours and provision is made for the partial evaporation of the crude oil in the heat-exchangers and the admission of steam. A series of heat exchangers is provided to ensure the economical use of the heat, and the quantity of hot residue passing through the heat exchangers is controlled by a valve on the hot residue main and a valve admitting hot residue to the heat exchanger, both operated by a worm. The apparatus operates in conjunction with a vertical still so arranged that vapours may be drawn off at different levels and consequently at different temperatures.—T. A. S.

Desulphurising oils [e.g., shale oil]; Means for ——. A. C. Nesfield. E.P. 183,527, 24.3. and 14.6.21.

The oil is treated in a thin film with chlorine gas. The treatment takes place in a tower down which the oil descends and is caused to form films by flowing over cones. The chlorine is circulated, but has to be replaced in time owing to loss of efficiency. The sulphur is precipitated in flocculent form and is separated from the oil by filtration, centrifugal treatment, or by means of water. The reaction is expedited by the addition of quicklime and by preheating the oil to a suitable temperature—for certain oils 100°—120° C. The precipitate consists of sulphur compounds in addition to sulphur and may contain bituminous matter.—T. A. S.

Desulphurising [mineral] oil; Process of ——. Process for obtaining sulphur compounds from mineral oils and the like. Method of desulphurising oil. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. (A) 1,423,710, (B) 1,423,711, and (C) 1,423,712, 25.7.22. Appl., 8.7., 14.7. and 17.7.20.

(A) The oil is treated with liquid anhydrous ammonia to cause the formation of an ammonia-sulphur compound which is then separated. A catalyst may be used to facilitate the formation of the ammonia-sulphur compound. (B) The sulphur compounds, separated from the oil as ammonia-sulphur compounds through the agency of liquid ammonia, are recovered. (C) Mineral oil is desulphurised by heating it with ammonia vapour and steam.—T. A. S.

Fuel for use in internal combustion engines. H. R. Ricardo. E.P. 183,577, 26.4.21.

The introduction of water into the cylinder of an internal combustion engine, with the object of reducing the temperature at which the engine works, cooling the piston, inlet and exhaust valves, is attained by using mixtures of benzol, acetone, and water with or without the addition of ethyl or methyl alcohol. At least 8% of water is required. A suitable fuel consists of 60% of ethyl alcohol, 20% of acetone, 10% of benzol, and 10% of water. —T. A. S.

Fuel. Fuel of liquid type. Liquid fuel. B. R. Tunison, Assr. to U.S. Industrial Alcohol Co. U.S.P. (A) 1,423,048, (B) 1,423,049, and (C) 1,423,050, 18.7.22. Appl., 12.4.20.

(A) A liquid fuel denser than kerosene consists of a relatively heavy aliphatic hydrocarbon and alcohol. (B) A liquid fuel consists of a petroleum distillate heavier than kerosene, an ester of an organic acid, and a monohydric alcohol, the heavy oil forming three-quarters of the mixture. (C) A liquid fuel consists of a petroleum distillate heavier than kerosene and an aromatic hydrocarbon.—T. A. S.

Fuel for use in internal combustion engines. M. C. Whitaker, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,423,058, 18.7.22. Appl., 12.11.19.

The fuel consists of benzol 17—35 pts., gasoline 20—50 pts., ethyl acetate 5 to 20 pts., and alcohol more than 20 pts. by volume.—T. A. S.

Fuel; Production of liquid —— from oils containing creosote. Maschinenfabr. Augsburg-Nürnberg A.-G. G.P. 351,817, 5.12.20.

COAL-TAR oil containing phenols is added to oils containing creosote to prevent formation of pitch and asphaltic deposits.—L. A. C.

Crude oil; Apparatus connected with an internal combustion or oil engine for converting —— into fuel. T. D. Key. E.P. 183,600, 2.5.21.

THE removal of impurities from crude oil is facilitated by heating it by means of the exhaust gases from the engine. The apparatus is so arranged that a thermo-siphon is set up. The oil passes through filters to remove suspended matter, and sumps are provided for the removal of water and asphalt. —T. A. S.

Transmission and motor oil. W. K. Boileau, Assr. to Pittsburgh Oil Refining Corp. U.S.P. 1,423,512, 25.7.22. Appl., 5.6.22.

AN oil for the lubrication of cylinders, bearings and transmission of internal combustion engines and the fabric lining of transmission and brake parts consists of petroleum oil of the ordinary consistency used in the cylinders of internal combustion engines combined with 2—12% of neutral wool-fat. —T. A. S.

Gasoline and the like; Process for producing ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,423,709, 25.7.22. Appl., 31.7.19.

THE vapour of hydrocarbon oil is cracked by submitting it to the catalytic action of mercury vapour.—T. A. S.

Shale; Process of distilling ——. E. E. Hedges. U.S.P. 1,423,716, 25.7.22. Appl., 13.6.21. Renewed 8.4.22.

OIL-BEARING shale is distilled in an elongated retort with constant agitation. The shale is moved along the retort, which is heated at one end to a temperature necessary to drive off the most volatile constituents and at the other end to a temperature sufficiently high to decompose water in the presence of carbon. The discharged gases pass backwards through the progressively cooler portions of the retort. Steam is admitted at the hotter end of the retort, from which the spent shale is removed. —T. A. S.

Sludge acids [from refining of mineral oils]; Method of treating ——. I. Hechenbleikner and T. C. Oliver, Assrs. to Chemical Construction Co. U.S.P. 1,423,766–7, 25.7.22. Appl., 25.1.22.

THE method consists in heating a weak sludge acid with agitation to concentrate it to an intermediate strength and then further concentrating the acid without agitation.—T. A. S.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Decolouring charcoal of high activity [from sulphite-cellulose waste liquor]; Process for the manufacture of ——. R. Adler. E.P. 165,788, 29.6.21. Conv., 5.7.20.

SULPHITE-CELLULOSE waste liquor, or the residue left after the manufacture of alcohol therefrom, is heated under a pressure of several atmospheres with an alkaline-earth hydroxide or with a neutral salt in order to precipitate the organic matter. The precipitate is pressed and dissolved in an alkaline solution. The solution is filtered if necessary and the filtrate is dried and carbonised. The product is suspended in water and carbon dioxide is passed into the suspension to convert the sulphides present into carbonates. The resulting alkali carbonate solution is separated from the charcoal for further use. Alternatively the charcoal may be washed with water before the conversion of sulphides into carbonates.—H. Hg.

Low temperature carbonisation of materials; Process of and apparatus for ——. G. Polysius. E.P. (A) 157,318, 10.1.21. Conv., 1.2.18. (B) 178,126, 10.1.21.

(A) COAL gravitates from a hopper on to a spiral conveyor which delivers it through gas-tight connexions into a horizontal rotary retort heated externally. The outlet end of the retort is fitted with an adjustable coke delivery which determines the amount of coal retained in the retort and which discharges through a gas-tight connexion into the upper part of a vertical coke shaft. The gas evolved from the retort passes through a condenser and then part of it enters the base of the coke shaft so as to carry the sensible heat of the coke into the retort. (B) The upper part of the coke shaft is fitted with a funnel which prevents direct passage of gas from the shaft to the retort. The gas leaving the shaft, before it enters the retort, passes through a regenerator where it is further heated by the combustion of part of the gas leaving the condenser. The products of combustion leaving the regenerator are used for heating the retort externally.—H. Hg.

Conductors for making electrical connexion with mercury. E.P. 183,683. *See* XI.

III.—TAR AND TAR PRODUCTS.

Thiophen series; Studies in the ——. XIII. Action of acetylene on pyrites. W. Steinkopf and J. Herold. Annalen, 1922, **428**, 123—153.

The product of the action of acetylene on finely divided pyrites at 300° C. contains the following substances: carbon, hydrogen, hydrogen sulphide, methane, butadiene, acetaldehyde, carbon bisulphide, acetone, benzene, thiophene (about 40%), 2-thiotolene, 3-thiotolene, 2.3-thioxine, 2-ethylthiophene, and 3-ethylthiophene, and probably, in addition, butane, ethylacetylene, toluene, xylene, and higher homologues of acetylene. (*Cf.* J.C.S., Sept.)—C. K. I.

Patents.

Distillation of coal tar, mineral oils, and the like; Stills for continuous ——. J. A. Yeadon. E.P. 183,682, 30.6.21.

A series of shallow oblong stills is used, through which the coal-tar or oil flows in succession by gravity. The bottoms of the stills are corrugated transversely thereby adding to the strength and heating surface of the stills. The stills are set at a slight inclination, and oil flows from one still to the next by means of a U-tube, so that the passage of vapour is prevented. Each still is fitted with its own condenser.—T. A. S.

Tar; Plant for the continuous distillation of ——. C. Schaer. G.P. 349,437, 16.3.16.

A fan, and an ejector supplied with air under pressure by the fan, are so arranged that the mouth of the suction tube of the ejector is located in the pitch delivery section of the plant. The conveyor tube of the ejector serves to condense the vapours passing through the tube, the condensed liquid being returned to the oil-collecting receptacle. One or more further ejectors may be used to provide the necessary draught for heating the still.—A. G.

Phenol: Production of pure —— free from homologues, from coal-tar oils. R. E. Ghislain. G.P. 355,388, 14.4.20.

A coal-tar fraction boiling between 175° and 200° C., and from which naphthalene has been separated by crystallisation, is treated with highly concentrated caustic soda solution, then with sulphuric acid of 66° B. (sp. gr. 1·84), avoiding rise of temperature above 80°—85° C. The black oil is separated, the remaining liquor decanted from the sodium sulphate solution, and the aqueous liquid is distilled. The process yields colourless, pure and crystalline phenol in quantitative yield.—A. G.

α-Ketohydronaphthalenes; Process for the preparation of ——. G. Schroeter, and Tetralin G.m.b.H. G.P. 352,720, 5.9.20.

α-Naphthol or iso- or heteronuclear substituted derivatives of α-naphthol are treated, either in solution or after fusion, with hydrogen under pressure until the amount absorbed corresponds to less than two molecules of the gas for each molecule of the substance. As a catalyst a finely divided precious metal or a metal, such as nickel, on some suitable carrier such as kieselguhr is used. For example, carefully purified α-naphthol is dissolved in tetrahydronaphthalene and the solution is heated in an autoclave with stirring under 10—20 atm. pressure of hydrogen to 120°—180° C., in the presence of kieselguhr coated with finely divided reduced nickel. When 1·5 mols. of hydrogen has been absorbed the process is interrupted and the solution, after cooling, filtered and subjected to fractional distillation under reduced pressure. At 14 mm. tetrahydronaphthalene distils at 100° C., the temperature then rises to 130°—137° C., and α-ketotetrahydronaphthalene (b.p. 134°—135° C. at 14 mm.) distils over. The higher boiling fractions consist of unused α-naphthol and *ar*-tetrahydronaphthalene and are used again in the process. β-Naphthol yields no keto-compound under similar conditions, the chief product of the reaction being *ac*-tetrahydro-β-naphthol. 1.5-Dihydroxynaphthalene yields 1-ketotetrahydro-*ar*-5-hydroxynaphthalene in colourless crystals, m.p. 156°—157° C., while 1.8-dihydroxynaphthalene gives 1-ketotetrahydro-*ar*-8-hydroxynaphthalene, and 1-hydroxy-5-acetaminonaphthalene gives 1-ketotetrahydro-*ar*-5-acetaminonaphthalene.—A. IV.—COLOURING MATTERS AND DYES.

Fluorescein; Formation and properties of ——. O. Fischer and M. Bollmann. J. prakt. Chem., 1922, **104**, 123—131.

In Fluorescein as ordinarily prepared there is at most only traces of monoresorcinolphthalein, a fact no doubt due to the instability of this compound at the temperature of the reaction. In presence of boric acid, however, the more stable boric ester is formed, and fair yields of monoresorcinolphthalein, m.p. 208°—209° C., are obtained. Oxonium salts of the methyl ethers of Fluorescein are described. (*Cf.* J.C.S., Sept.)—W. O. K.

o-Aminoazo compounds; Constitution of the products arising from the condensation of —— with aldehydes. O. Fischer. J. prakt. Chem., 1922, **104**, 102—122.

The colourless bases obtained by Goldschmidt by the action of aldehydes on *o*-aminoazo compounds and considered by him to be triazines, are shown to be derivatives of N-aminobenziminazole, as they are decomposed by hydrogen iodide into a derivative of benziminazole and an amine, and they can be synthesised from such a benziminazole derivative by heating the chloroimine, obtained from it on treatment with hypochlorite, with a base. (*Cf.* J.C.S., Sept.)—W. O. K.

Camphoric anhydride; Dyes derived from ——. A. C. Sircar and S. Dutt. Chem. Soc. Trans., 1922, **121**, 1283—1286.

Dyestuffs of the phthalein type were prepared by the condensation of camphoric anhydride with phenols and amines by means of zinc chloride. The depth of colour and intensity of fluorescence of these dyestuffs were similar to, if not more marked than, those of the corresponding compounds from phthalic anhydride, but their isolation was very tedious and difficult on account of the large proportion of tarry by-products which was produced. Resorcinolcamphorein is a reddish-brown powder, and its sodium salt dyes wool brick-red shades. Its tetrabromo derivative dyes wool and tannin-mordanted cotton brilliant pink shades. *m*-Dimethylaminophenolcamphorein hydrochloride forms glistening green prisms, m.p. 125°—126° C.; its solutions exhibit an orange fluorescence, and dye pink shades on wool, and reddish-violet on tannin-mordanted cotton. Phloroglucinolcamphorein forms orange-red needles, and dyes orange shades. *m*-Aminophenolcamphorein is a brown powder exhibiting in solution a dark green fluorescence. *m*-Phenylenediamine-camphorein crystallises in brownish-yellow prisms, m.p. 234° C. (with decomp.). Its solutions show a green fluorescence. —G. F. M.

Camphoreins. Studies in optically active dyes. I. B. K. Singh, R. Rai, and R. Lal. Chem. Soc. Trans., 1921, **121**, 1421—1430.

A SERIES of camphoreins was prepared by condensing camphoric anhydride with phenol, *o*-cresol, quinol, catechol, phloroglucinol, and pyrogallol. The condensation was best effected by means of stannic chloride in the first three cases; zinc chloride was used for catechol, and a few drops of sulphuric acid in the case of phloroglucinol and pyrogallol. Optical rotation was observed and measured in the case of *o*-cresolcamphorein, $[\alpha]_D = +93°$, but in other cases the deep colour of the solutions prevented observation. Some of the dyestuffs diffuse easily through animal membranes, and have staining properties for animal and vegetable tissues, and it is suggested that, being optically active, they might have special value as selective histological stains. Phenolcamphorein dyes wool and silk yellow from a bath containing sodium sulphate and excess of sulphuric acid with chrome and iron mordants. The cresol- and quinol-camphoreins have poor dyeing properties. Catecholcamphorein exhibits a green fluorescence in sulphuric acid solution. Pyrogallolcamphorein dyes wool deep brown shades on chrome, aluminium, tin, and iron mordants. Tetrabromoresorcinolcamphorein was obtained as a reddish-yellow powder, m.p. 133°—135° C. The position of the absorption bands of the above compounds was determined.
—G. F. M.

Anthracene series; Studies in the ——. II. E. de B. Barnett and J. W. Cook. Chem. Soc. Trans., 1922, **121**, 1376—1391.

MONOHYDROXYANTHRAQUINONES and dihydroxyanthraquinones which do not contain two hydroxyl groups in the *ortho*- or *para*-positions with reference to one another, when treated with bromine in presence of a large excess of pyridine do not give pyridinium salts, but are merely brominated. Quinizarin, on the other hand, is not brominated, but is converted into quinizarin-2.3-dipyridinium dibromide, probably through the intermediate formation of a diquinone, which forms a dibromide. This then unites with two mols. of pyridine with simultaneous enolisation. A similar reaction occurs with hystazarin. In the case of alizarin, 3-bromo-alizarin is produced if only 1 mol. of bromine is used with 2 mols. of bromine, or on further treatment of 3-bromoalizarin, 3-bromoalizarinpyridinium bromide is formed, whilst 3 mols. of bromine converts alizarin into alizarindipyridinium dibromide. Similar compounds are obtained from 3-nitro- and 4-nitroalizarin. All these pyridinium salts pass with varying ease into betaine-like compounds by loss of hydrogen bromide, either spontaneously, or when recrystallised from alcohol and ether. The betaine formation probably occurs between a β-hydroxyl group and the pyridinium group in the *ortho*-position to it. During the course of the research it was found incidentally that the nitration of 3-bromoalizarin yields 3-nitroalizarin, and conversely bromination converts 3-nitroalizarin into 3-bromoalizarin, contrary to what would have been expected from the behaviour of the corresponding chloro-derivative.
—G. F. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Preparation of —— by means of chlorine gas. U. Pomilio. Chim. et Ind., 1922, **8**, 41—45.

THE De Vains process for the preparation of cellulose by means of a solution of chlorine under pressure as described by De Perdiguier (*cf.* J., 1922, 288 A) is compared with that of Cataldi, who **employs gaseous chlorine, and is adversely** criticised **in that it requires more caustic soda and fuel** and **less chlorine, which is the cheapest reagent,** than **the latter process, the yield by which is higher** than that of any process yet known. In the Cataldi process the greater part of the chlorine (sometimes as much as 80%) is eliminated during the chlorination as hydrochloric acid, which is readily removed from the apparatus without neutralising or raising the temperature. The cellulose produced from poplar averages 74% of α-cellulose and 21% of the β and γ varieties, and contains 1·7% of ash. The average length of the fibres is 1·1 mm. and their mean diameter 0·026 mm. The process is operating successfully at Naples.—A. R. P.

PATENTS.

Artificial silk; Composition for the treatment of ——. C. A. Snyder. U.S.P. 1,423,041, 18.7.22. Appl., 3.9.21.

ARTIFICIAL silk thread is finished with a composition consisting of olive oil soap dissolved in water to which olive oil is added.—T. A. S.

Artificial fabrics containing nitrocellulose; Process for increasing the softness and elasticity of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. (A) 353,233, 4.4.20, and (B) 353,234, 13.4.20.

(A) THE nitrocellulose is worked up with the addition of acetals of fatty-aromatic alcohols. Benzylacetal, from acetaldehyde and benzyl alcohol, an oil boiling at 198° C. at 20 mm., and xylylacetals boiling about 12° higher, are superior to the softening media previously used on account of their great stability. (B) The nitrocellulose is treated with aliphatic-aromatic ethers of polyhydric alcohols, *e.g.*, the dibenzyl, dixylyl, or dichlorobenzyl ethers of glycol, or the tribenzyl or dibenzyl ether of glycerol. Films are obtained of great flexibility, strength, and elasticity.—A. G.

Wood pulp; Process for making ——. L. Enge. G.P. 353,105, 16.7.21.

THE wood is treated with a bleaching agent immediately after boiling or steaming and before grinding. The bleaching is carried out either in the boiler or in another closed vessel. The wood is completely saturated with the bleaching liquid by keeping it for some time in an evacuated vessel and then treating it either with an aqueous solution of the bleach under pressure or with "warm air almost completely saturated with this solution." Gaseous bleaching agents may also be used. If solutions of bisulphites, such as sodium bisulphite, are used as bleaching agents, the wood must be allowed to lie for several days after treatment before it is separated into fibres. The incrustation is thereby also softened, so that a very tough fibrous pulp can be obtained from the bleached raw wood.—H. C. R.

Sizing paper; Process for ——. L. Ubbelohde. G.P. 303,324, 18.7.16, 305,006—305,010 dated 14.11.16, 31.12.16, 31.12.16, 9.2.17, 31.12.16, respectively, and 307,098, 9.2.17.

MATERIALS composed mainly of humic acid and its salts are employed for sizing paper and finished pieces and products made of paper. Humic acid is soluble in water and in dilute alkalis, but when dried into the paper it behaves as an irreversible colloid and is no longer soluble in water. Humic acid can be obtained from substances containing it or from peat. The solution obtained by treating peat or lignite with alkalis can be used directly for sizing paper or for impregnating paper or paper goods. This solution, equally with humic acid solution, can be precipitated with acids or metallic salts. Humous, bituminous or similar material, such as peat and lignite, can also be fractionally dissolved by treatment with various alkalis or alkaline solutions and the fractions, either alone or mixed together, can be used for sizing. The liquids obtained are more or less cloudy colloidal solutions or suspensions. The solutions obtained by bleaching humic acid solutions, crude humic acid, or the fractions obtained from these acids with chlorine can also be used for sizing paper and for impregnating paper and paper goods. In order to improve the sizing action of these materials, small quantities of other materials, such as water glass, beech wood tar size, coumarone resin emulsions, vegetable mucilage or sizes, such as are used as substitutes for rosin-size in the sizing of paper, may be added. The addition of these substances is also of advantage in the impregnation of paper goods. A better incorporation of the bituminous matter is also obtained by the use of other known sizing materials such as rosin size or animal size at the same time. Ferric sulphate forms a valuable substitute for the commonly used precipitating agents in the sizing of material with solutions of humic acid.—H. C. R.

Paper; Method for sizing —— with animal glue or proteins. Badische Anilin- und Soda-Fabr. G.P. 349,881, 23.1.17. Addn. to 331,350 (J., 1921, 384 A).

Artificially prepared, organic glue precipitants other than the sulphonic acids described in the chief patent, preferably in the presence of resin size, resin soap, or resin emulsions, are used for sizing paper with animal glue or proteins. For example, solutions containing 0·25% of resin size, 2% of animal glue, 4% of the condensation product from cresolsulphonic acid and formaldehyde ("Neradol D"), and 1—2% of aluminium sulphate, the weights being reckoned on the weight of the dry material, are added to the material in the hollander, and the material is subsequently worked up in the usual manner.—L. A. C.

Adhesive; Preparation of an —— from waste cellulose liquors. H. P. Kaufmann. G.P. 353,570, 30.7.19. Addn. to 352,138 (J., 1922, 641 A).

In place of calcium oxide equivalent quantities of other alkaline earths or of magnesia or magnesium hydroxide are used, and ammonium salts may be used instead of salts of the alkalis. For example, the mixture may consist of 5 pts. of cellulose pitch, 2·5 pts. of casein, 1·9 pts. of magnesia, and 1 pt. of sodium fluoride.—A. R. P.

Textile products derived from animal fibres; Manufacture of ——. A. G. Bloxam. From Technochemia A.-G. E.P. 183,249, 21.4.21, and 183,270, 27.4.21.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Tannin, Tamol and Katanol [; Comparison of —— as mordants for basic dyestuffs]. H. Wagner. Farben-Zeit., 1922, 27, 3015—3016.

The mordanting properties of tannin and its substitutes, Tamol (a formaldehyde compound of a naphthalenesulphonic acid) and Katanol (a thiophenol), have been compared in the case of Auramine, Safranine T, Rhodamine B, Methyl Violet B, Methylene Blue BG, and Brilliant Green. Dyeings obtained by means of Tamol and Katanol, though slightly inferior in fastness to light, have a greater fastness to lime than dyeings obtained by means of tannin. On the whole, Tamol and Katanol are superior to tannin as mordants for basic dyestuffs, since they are cheaper and yield purer shades. —A. J. H.

Patents.

Soluble vat-preparations for dyeing; Manufacture of stable, dry and readily ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 171,078, 15.6.21. Conv., 1.11.20.

Stable, dry and readily-soluble vat-preparations, particularly those containing a sulphurised or non-sulphurised quinone vat dyestuff capable of dyeing wool, are prepared by evaporation to dryness, preferably *in vacuo*, of a mixture containing about equal amounts of an alkali leuco-salt of the vat dyestuff and an alkali leuco-salt of Indigo, together with an agglutinating or diluting agent when necessary.—A. J. H.

Paper or fabric surfaces that have been treated with proteins; Process for producing water- and friction-resisting print or colourings on ——. Exportingenieure für Papier- und Zellstofftechnik G.m.b.H. G.P. 303,372, 29.9.15.

The printing ink or colour contains the same or a similar protein to that used in producing the surface on the paper or fabric, and after printing, the whole mass is subjected to treatment with a hardening material which renders all the protein present insoluble in water. For example, if animal glue or casein is used as the protein, the finished print is sprayed with a solution containing tannic acid or chromium compounds and set aside until the surface hardens. To increase the capacity of the prepared paper to absorb water and to obtain sharp prints, an extract of horse-chestnuts is added to the ink, and to increase the resistance of the finished print to water it is coated with a protein solution and again subjected to hardening. The paper may also be treated with a hardening agent before printing. —A. R. P.

Animal fibres; Process for protecting —— in treating them with alkaline liquids. A. G. Bloxam. From Act.-Ges. für Anilinfabrikation. E.P. 183,868, 27.1.21.

See U.S.P. 1,419,497 of 1922; J., 1922, 584 A. Instead of sulphite-cellulose waste liquor, an active constituent of the liquor, *e.g.*, sodium ligninsulphonate or "cell pitch," or a sugar may be used.

Dyeing apparatus. Jackson and Bro., Ltd., G. P. Gass, R. Hammond, and J. R. Fish. E.P. 183,526, 24.3.21.

Starch. G.P. 351,370. *See* XVII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrochloric acid; A new vessel for the absorption of ——. S. L. Tyler. Chem. and Met. Eng., 1922, **27**, 223—225.

Hydrochloric acid is absorbed by water in a series of broad vessels made of fused silica, connected to form a number of S-bends, and constituting a single conduit through which the gases and water flow. Liquid is retained in each vessel by means of a weir. The roof of each vessel slopes downwards on each side towards the middle, where there is a depression from which condensed liquid drips, forming a curtain through which the gases pass. Packed towers may be arranged between the absorption vessels. Absorption systems suitable for use with the gases from the pan and muffle sides respectively of a hydrochloric acid plant are described. —J. S. G. T.

Potash; Elimination of borates from American ——. W. H. Ross and W. Hazen. Chem. and Met. Eng., 1922, **27**, 167—170.

Potassium chloride produced from the brine of Searles Lake may contain as much as about 25% of borax. Serious injury to crops results from the use of such potassium chloride as a fertiliser. By rapid cooling of the mother liquors containing the potassium salts a high-grade potassium chloride containing less than 0·5% of anhydrous borax is now being prepared from the brine. The product meets the requirement of the U.S. Department of Agriculture limiting the borate content of potassium salts used as fertilisers to a maximum of 0·5—1% of anhydrous borax.—J. S. G. T.

Potassium iodide; Adulteration of —— *with potassium bromide.* J. Grossmann. Pharm. Zeit., 1922, **67**, 689.

Attention is drawn to the occurrence of potassium iodide adulterated with considerable proportions (up to 25—30%) of potassium bromide, and to the inadequacy of the usual test for bromide, owing to the sparing solubility of silver bromide in ammonia. It is recommended that in all cases attention should be paid to the colour of the silver iodide precipitate (darkening on exposure to light occurs more rapidly when bromide is present) and that in doubtful cases the precipitate should be tested for bromide by distillation with ferric chloride.—H. R. D.

Iodates; Detection of —— *in potassium iodide according to the French Codex,* 1908. Lachartre. J. Pharm. Chim., 1922, **26**, 134—138.

The test for iodates in potassium iodide described in the Codex lacks precision, and takes no account of the influence of such factors as the strength of the iodide solution, the amount of acid added, the duration of the reaction, etc. The following method is suggested: A 10% solution of iodide in distilled water is prepared, and to 10 c.c. 3 c.c. of chloroform and 5 drops of glacial acetic acid are added. After shaking for 30 secs. the chloroform, examined immediately after separation, should not be coloured. Performed in this way the limit of sensitiveness of the test is 0·08 pt. per 1000. The presence of small quantities of copper, *e.g.*, 0·0015 pt. per 1000, has no effect on the reaction with a perfectly pure iodide, but appreciably accelerates the development of the iodine coloration when traces of iodate are present. The amount of copper in ordinary distilled water is, however, too small to have any effect on the reaction in either case.—G. F. M.

Sulphites; Oxidation of —— *in concentrated solutions.* J. Milbauer and J. Pazourek. Bull. Soc. Chim., 1922, **33**, 676—678.

A study of the oxidation of sodium sulphite solutions of different concentrations. The rate of oxidation increases with dilution, but is considerably decreased by the presence of carbonic and sulphurous acids. Feebly alkaline solutions are more rapidly oxidised than neutral solutions, but when strongly alkaline the rate of oxidation, even in the presence of catalysts, is diminished. In neutral solutions of all concentrations salts of cobalt are good catalysts, whilst copper salts only function in dilute solutions of high purity. In concentrated solution, sulphites of sodium, potassium, and ammonium behave similarly, both with and without catalysts; in each case, especially with ammonium sulphite, impurities retard oxidation. —H. J. E.

Sulphides; Estimation of —— *by oxidation with ferric sulphate.* P. P. Budnikow and K. E. Krause. Ber. Polyt. Iwanowo Wosniessensk, 1921, [4], 157—159. Chem. Zentr., 1922, **93**, IV., 106—107.

Sodium sulphide solution to which a small quantity of sodium carbonate is added is treated slowly with a 40% solution of ferric sulphate, boiled for 10—15 mins. to oxidise any ferrous sulphide to ferrous sulphate, acidified with sulphuric acid, and then titrated with potassium permanganate. At first it is necessary to keep the solution alkaline to prevent interaction between the ferrous sulphate and sodium sulphide. The method is only applicable to sulphides soluble in water and acids, such as those of sodium, calcium, zinc, etc.—J. B. F.

Phosphates; Estimation of iron and aluminium in natural ——. O. Nydegger and A. Schaus. Bull. Fed. Ind. Chim. Belg., 1922, **1**, 405—407.

Von Gruebeb's method (Prost, Manuel d'anal. Chim., 105) consists in neutralising the solution of the phosphate in hydrochloric acid with 20% caustic soda, adding excess of the latter, boiling the solution to convert aluminium phosphate into aluminate, filtering, acidifying the solution, and precipitating the aluminium as phosphate by means of ammonia. The iron is estimated by titration with permanganate. The authors show that this method is not accurate, the aluminium not being precipitated quantitatively as phosphate, as the preliminary preparation of the solution removes phosphoric acid, so that insufficient remains for the purpose. The error is obviated by the following procedure: 12·5 g. of the phosphate is dissolved in hydrochloric acid and the solution evaporated to dryness to render the silica insoluble. After again dissolving in hydrochloric acid, the solution is diluted, boiled, and made up to 250 c.c. Of this, 100 c.c. is used for estimation of iron and a further 100 c.c. for aluminium. To the latter 10—20 c.c. of a 10% solution of sodium phosphate is added, the whole neutralised with caustic soda, a further 20 c.c. of sodium phosphate added, and the mixture boiled for 5 mins., or until the precipitate is of a brick-red colour. After cooling, the solution is diluted to 250 c.c., filtered, 100 c.c. of the filtrate (equivalent to 2 g. of phosphate) acidified with hydrochloric acid and the aluminium precipitated as phosphate with ammonia, care being taken to avoid an excess of the latter. Control experiments show this modification of the method to be trustworthy.—H. J. E.

Silica and sodium chloride; Interaction of ——. F. H. Clews and H. V. Thompson. Chem. Soc. Trans., 1922, **121**, 1442—1448.

Silica and sodium chloride when strongly heated interact to give, in dry air, sodium silicate and chlorine; in moist air sodium silicate, hydrochloric acid, and a small quantity of chlorine; in moist nitrogen, sodium silicate and hydrochloric acid. The lower temperature limit of the reaction is about 600° C., and the extent of the reaction is still very small at 1000° C. Rise in temperature and presence of moisture increase the velocity of the reaction to a considerable extent. The results obtained by varying the proportions of sodium chloride and silica indicate that the area of contact is more important than the composition of the mixture, unless the proportion of salt falls much below 50%. When quartz is heated with sodium chloride at 1000° C. it is converted into tridymite. The conversion is probably the result of recrystallisation from a solution of quartz in the molten chloride. At 1000° C. quartz is more reactive than precipitated silica or tridymite to sodium chloride.—J. B. F.

Monazite; Attack and analysis of ——. P. Wenger and P. Christin. Ann. Chim. Analyt., 1922, **4**, 231—232.

The hitherto published methods for the attack of monazite are either tedious or else leave large quantities of the rare earths undissolved. By the following method the whole of the mineral can readily be brought into solution. About 1 g. of the finely ground material is heated for 5 hrs. with 5 c.c. of sulphuric acid (sp. gr. 1·84) at 230° C. The resulting pasty mass is gradually poured into iced water, when all but a small residue passes into solution. This is filtered off and again heated with sulphuric acid, a little hydrofluoric acid being added to volatilise the silica. The residue is then melted with 6 pts. of sodium carbonate. On treatment with water the tantalum passes into solution, and any slight residue still remaining will be zirconia and may be brought into solution by fusion with potassium bisulphate. In the subsequent analysis the rare earths should be precipitated by oxalic acid at 55° C. in a solution containing 0·15—0·75% of sulphuric acid and with an excess of 3% of oxalic acid. At this temperature precipitation may be considered quantitative for yttrium, thorium, cerium, and didymium. Lanthanum oxalate, being the most soluble, is not completely precipitated, and 50 c.c. of the solution under the above conditions would retain 0·011 g. in solution.—G. F. M.

Ferrosilicon; Formation of —— in carbide works. O. Hackl. Chem.-Zeit., 1922, **46**, 740.

In the manufacture of calcium carbide at Austrian and Bavarian works a number of brittle metallic reguli were obtained which proved to be ferrosilicon containing a high percentage of silicon.—A. R. P.

Catalysts; Behaviour of certain metals as ——. *I.* C. Sandonnini. Gazz. Chim. Ital., 1922, **52**, I., 394—408.

Experiments have been made on the changes occurring, under the influence of various metallic catalysts, in systems containing detonating mixtures of hydrogen and oxygen together with a compound capable of ready oxidation or hydrogenation, such as ethylene, phenanthrene, nitrobenzene, and allyl alcohol. The velocity of the formation of water from hydrogen and oxygen in presence of finely divided nickel is very greatly diminished by addition of ethylene, although at the ordinary temperature it is the only reaction which proceeds to an appreciable extent. When the temperature is raised the hydrogenation of ethane proceeds with increased velocity and oxidation of ethylene also becomes appreciable. At 225° C. most of the ethylene is hydrogenated to ethane. When copper is used as catalyst it is markedly oxidised, and this favours oxidation phenomena. In mixtures of hydrogen, oxygen, and nitrobenzene, the reduction of the last-named in presence of nickel is more rapid than the formation of water from the hydrogen and oxygen. (*Cf.* J.C.S., 1922, ii., 557.)—T. H. P.

Detonating gas; Combination in —— in presence of colloidal palladium solution. C. Sandonnini and A. Quaglia. Gazz. Chim. Ital., 1922, **52**, I., 409—416. (*Cf.* preceding abstract.)

Experiments with mixtures of hydrogen and oxygen in different proportions in presence of colloidal palladium solution showed that the velocity of combination is proportional to the concentration of detonating gas ($2H_2+O_2$) in the mixture. With mixtures having the same concentration of detonating gas the reaction velocity is greater when excess of hydrogen is present than in presence of excess of oxygen. When the gas mixture contains reducible compounds (ethylene, allyl alcohol, nitrobenzene, sodium phenylpropiolate), in addition to hydrogen and oxygen, hydrogenation reactions may occur as well as formation of water, and it is concluded that the reactions are due to active or atomic hydrogen. (*Cf.* J.C.S., 1922, ii., 556.)—T. H. P.

Sulphur; Solubility of —— in certain organic liquids. R. Delaplace. J. Pharm. Chim., 1922, **26**, 139—140.

The solubility of sulphur in chloroform, carbon tetrachloride, benzene, toluene, and ether was determined at various temperatures ranging from 13° C. to 24° C. The divergence of the results from those obtained by earlier workers is attributed in some cases to the slowness of saturation, continuous agitation for 12 hrs. being required to obtain saturated solutions in benzene and toluene for example. From the results, which are given in tabular form, the following figures for the weights of sulphur dissolved in 100 g. of solvent are abstracted:—In chloroform at 15° C., 0·874 g.; in carbon tetrachloride at 15·5° C., 0·723 g.; in toluene at 20° C., 1·857 g.; in benzene at 15° C., 1·582 g., and in anhydrous ether at 13° C., 0·188 g. —G. F. M.

Patents.

Sulphuric acid; Manufacture of ——. G. Mirat and P. Pipereaut. E.P. 163,030, 13.4.21. Conv., 6.5.20.

The apparatus consists of ten small lead chambers of 280 cub. m. capacity, arranged in series with inlets at the top and outlets near the bottom. The long connecting pipes are rectangular in section and are fitted with superimposed troughs down which a current of water flows. The usual Glover tower is provided, but between the last chamber and the Gay Lussac tower is interposed a series of ten stoneware collectors of 1000 l. capacity, of which the first four contain water and the others strong sulphuric acid. "From this apparatus the gases enter the coke tower deprived of NO_2, which is not soluble in the sulphuric acid and would not be decomposed within the coke tower."—C. I.

Ammonia; Synthesis of —— from its elements and catalyst therefor. The Nitrogen Corp. Assees. of J. C. Clancy. E.P. 156,698, 7.1.21. Conv., 7.1.20.

A catalyst for ammonia synthesis, consisting of a sation of salt from the fuel and its subsequent deposition on the burned ware where it is changed partly to the sulphate by the action of the oxides of sulphur evolved by the fuel.—H. S. H.

Terra-cotta; Shivering of ——. J. L. Carruthers. J. Amer. Ceram. Soc., 1922, **5**, 518—526.

A WHITE matt glaze which had shivered badly in use was applied to bodies prepared from six terra-cotta clays, one non-shivering clay, and one badly shivering clay, and fired to cone 3. Shivering was caused by the presence of finely-divided silica in the body due to the use of highly silicious clays or finely-ground grog of a silicious nature, the presence of soluble salts in the clay, grog, or tempering water, or from too long a firing period. It was eliminated by using a flux such as felspar, felsite, or similar rock to overcome the action of the finely-divided silica, by using a coarse grog or sand so as to give an open structure, and by using barium carbonate to overcome the effects of the soluble salts.—H. S. H.

Zinc oxide [*ceramic*] *bodies; Some properties of* ——. E. E. Libman. J. Amer. Ceram. Soc., 1922, **5**, 488—491.

PURE zinc oxide was moistened with 20% of water and pressed into small cylinders which were heated for several hours in a closed platinum box in a platinum resistance furnace at 1400° C. After cooling the cylinders had a sparkling coarsely crystalline structure, and were probably identical with the mineral zincite. The melting point was above 1800° C. The shrinkage and porosity of the cylinders were determined after heating at temperatures differing by 100° C. from 1000° C. to 1600° C. The shrinkage increased uniformly with rise of temperature, but the porosity decreased gradually to a minimum at 1350° C. and then increased as the temperature was raised, a result due to the gradual growth of large crystals at the high temperatures. In the discussion E. W. Washburn pointed out the possible advantages of incorporating zinc oxide in a zinc retort body.—H. S. H.

Porosity of highly vitrified [*ceramic*] *bodies; Determination of the* ——. E. W. Washburn and E. N. Bunting. J. Amer. Ceram. Soc., 1922, **5**, 527—537.

THE limits of accuracy of the general laboratory research type of porosimeter (J., 1922, 176 A, 217 A, 253 A) are discussed and the principles of design indicated. A new type of porosimeter is described with which the pore volume of any test piece may be determined directly within 0·01—0·02 c.c. Tests of eight pieces of electrical porcelain gave porosities of ±0·01%, results which were confirmed by dye-penetration tests. A simple apparatus for rapidly measuring the porosity of a full size brick is described.—H. S. H.

Tunnel kiln; The Harrop ——. W. E. Cramer. J. Amer. Ceram. Soc., 1922, **5**, 492—499.

THE Harrop car tunnel kiln has been used successfully for the firing of electrical porcelains placed in saggars. The kiln was operated at cones 10, 11, and 12, depending upon the ware being fired. Natural gas was used as fuel, but the kiln can also be fired with oil or coal. Ware has been fired through the kiln in 48 hours. The kiln produces a very uniformly fired product, while the fuel and labour charges and the capital cost are considerably less than for periodic kilns of the same capacity. —H. S. H.

Furnace; New type of gas-fired vitreous enamelling ——. H. H. Clark. J. Amer. Ceram. Soc., 1922, **5**, 478—487.

THE furnace has a working chamber 4 ft. wide, 3 ft. high, and 10 ft. long, and is heated by 5 gas burners on each side supplied with town gas. It can be brought to the working temperature in less than an hour, and in addition to being very economical in fuel, labour, initial cost, and repairs, it produces ware with a very high gloss.—H. S. H.

Silicates; Adsorption and dissolution of gases by ——. (*"Spit-out."*) B. Moore and J. W. Mellor. Trans. Ceram. Soc., 1921-22, **21**, 289—316.

"SPIT-OUT" results from the production and bursting of bubbles in glazes on firing in the enamel kiln at 700°—900° C. It may be caused by the sulphur dioxide and oxygen set free as a result of the diminution in the solubility of sulphates by an increase in the acidity of the glaze brought about by dissolution of silica from the body by the glaze, by the volatilisation of "lead" from the glaze, or by the absorption of "lead" by the body from the glaze. A similar result is produced by the reduction of stable sulphates to unstable sulphites. Microscopical examination of numerous glazes showed that few cases of "spit-out" were caused by the bursting of bubbles which were imprisoned in the glaze during glost firing. The absorption of hydrocarbon gases by glazes when cooling in an atmosphere of coal gas was shown experimentally. Large amounts of hydrocarbon vapours are generated in the earlier stages of firing muffles containing ground laid ware, ware decorated with oils, and lithographed ware. The glaze may then become charged with combustible gases which on heating in an oxidising atmosphere may burn below the surface of the glaze forming steam and carbon dioxide and giving rise to local heating, which will soften the glaze locally and facilitate "spitting." A certain amount of solid carbon may enter the glaze and if its subsequent combustion is rapid, "spitting" will result. The glaze may take up abnormal amounts of gas when hard fired and reject it in the form of "spits" in cooling, a result which is frequently accompanied by devitrification. Silicious glazes or glazes on highly silicious bodies, calcareous glazes, and all glazes having a tendency to devitrification in the enamel kiln are liable to this defect, which is corrected by the addition of alumina. It is important that enamel kilns should be well ventilated, so that oils distilled from the hot ware are not condensed on cooler ware, but are carried out of the kiln. The inside of hollow-ware is frequently "spitted" when the outside is good, owing to the difficulty of renewing the atmosphere inside the ware. If organic matter in the body has been imperfectly oxidised in the biscuit oven, the entry of air into the body in any subsequent firing causes the combustion of the organic matter, and the resulting products of combustion, heated by the reaction, are forced through the glaze, causing "spitting." Bad ventilation of the oven permits hydrocarbons and moisture to collect round the ware and so prevent the ingress of oxygen until a high temperature is reached, when the carbonaceous material burns with violence and damages the glaze. Carbonaceous matter may also be absorbed by the body in the ovens or kiln and burned out at a higher temperature. The rapid evolution of moisture absorbed by the body is a frequent cause of "spitting" and the authors consider that the presence of moisture or organic matter in the body causes 80% of the "spitting" which occurs in the manufacture of pottery. Any cause which favours absorption of moisture by the biscuit or glaze, and abrupt rises of temperature favouring an explosive evolution of steam etc. should be avoided.—H. S. H.

Glaze-fit; Control of —— *by means of tensile test specimens.* F. H. Riddle and J. S. Laird. J. Amer. Ceram. Soc., 1922, **5**, 500—503.

THE selection of a suitable glaze for a particular

body by the usual inspection of a field of glaze trials is not sufficiently precise and gives no indication of slow crazing tendencies. The effect of glazes on the tensile strengths of electrical porcelain test pieces was determined, and it was found that the best fitting glazes increase the strength, while the poorer ones decrease it. Glazes which craze weaken the specimens very markedly owing to the production of strains in the surface layer of the porcelain.
—H. S. H.

Patents.

Glass furnace; Electro-fining ——. W. G. Clark. E.P. 161,192, 6.4.21. Conv., 6.4.20.

The glass is maintained in the molten state in a vessel heated directly by gas or other suitable fuel, and at the same time an electric current is passed through the molten mass for fining the glass. The distance between the electrodes immersed in the molten glass is gradually increased as the temperature rises, so as to maintain a constant electrical resistance between them. Direct current or alternating current of low frequency is unsuitable owing to the tendency to decompose the oxides of the glass. No such decomposition occurs if the frequency of the alternating current is greater than 60 cycles.
—H. S. H.

Glass furnaces. J. S. Atkinson, and Stein and Atkinson, Ltd. E.P. 183,373, 26.8.21.

In tank furnaces fired by means of horseshoe or side firing and which may be arranged so that the flames have reverberatory effect, the recuperator, fixed under the tank, is made of special heat-exchanging blocks (E.P. 182,075) which are provided with ribbed internal passages increasing the area exposed. These blocks are built up so that the internal passages are vertical throughout the length, and the secondary air is drawn up through these passages. The producer is built right up to the furnace. The heat-exchanging blocks in the recuperator are set so as to provide ample room between them for the passage of waste gases. In the case of the transversely fired type, the recuperator is in two parts, one under each side of the tank.—A. C.

Furnaces; Glass and other ——. C. S. Stafford. E.P. 183,572, 25.4.21.

A waterproofing material is applied to the outer face of the furnace blocks to enable water cooling to be applied without injury to the blocks or causing devitrification of the glass by penetration to the inner surface of the block. Molten metal, *e.g.*, brass, or a vitreous enamel may be sprayed on by any known apparatus. If necessary the block may be coated prior to assembly and the joints faced over. An oxyhydrogen burner rather than an oxyacetylene one should be used with metal, as the surface is then less porous. Means for applying the water and removing the drainage are indicated. A cement to be applied before spraying and which is non-shrinking and less porous than the blocks is composed of 60% of grog, 38% of fireclay, and 2% of sodium silicate, ground very fine and thoroughly mixed.—A. C.

Moulds; Metallic —— *for forming glass articles.* R. L. Frink. E.P. 183,582, 26.4.21.

Moulds with vasculer or finely pitted surfaces are used which, when dipped in water or other fluid, retain sufficient to provide a vapour cushion when the hot glass is blown in, thus preventing actual contact of the glass with the mould, resulting in a finer polish on the glass and less wear on the mould. Mineral oil or tallow may be used as lubricant under special conditions. Suitable alloys for the whole mould or the inner lining to provide the necessary vascular condition of the surface are those of copper or aluminium with alkaline-earth metals or magnesium, *e.g.*, aluminium alloyed with 4% of calcium and 1% of barium. The pitted surface of the necessary character for the particular type of ware is produced by treating with alkali hydroxides for a suitable period, and sometimes by additional heat treatment. A "master alloy" which can be mixed with aluminium to give the required properties is given as 75% of aluminium and 25% of barium or calcium. The temperature to which it is heated before casting has a great effect on the characteristics of the product.—A. C.

Ceramic materials, glass and glazing; Production of ——. Ges. für Tuff- und Ton-Technik m.b.H. E.P. 166,558, 18.7.21. Conv., 20.7.20.

Pumice tuff which has previously been freed mechanically or chemically from extraneous substances is employed in the production of ceramic materials, glass, and glazes.—H. S. H.

Gas producers, electric furnaces, crucible furnaces, and the like [; *Refractory linings for* ——]. Ferolite, Ltd., and H. B. Clapp. E.P. 183,219, 15.4.21.

A material suitable for resisting the action of heat and fuel ash in furnaces is prepared by mixing 1 pt. of chromite crushed to pass through a $\frac{1}{8}$ in. mesh with 1 pt. crushed to pass through a $\frac{1}{16}$ in. mesh. About 5% of finely ground ferrosilicon containing about 70% Si is suspended in about 10% of a sodium silicate solution and incorporated with this mixture to give a plastic mass which may be made into bricks or tamped around a core.—H. Hg.

Synthetic jewel bearing. T. G. McDougal and S. J. McDowell, Assrs. to Champion Ignition Co. U.S.P. 1,422,216, 11.7.22. Appl., 14.1.20.

A process of manufacturing a synthetic jewel bearing consists in mixing two batches of ingredients which when fused form glasses of high viscosity, one of the batches having a higher fusing point than the other. A body for the bearing is compressed from the batch of higher fusion point, additional material from the other batch being compressed with it to form a facing. The bearing is then fused while supported on powdered material to which it will not adhere when fused, and is subsequently annealed.
—H. S. H.

Zinc retorts and other refractory shapes; Making of ——. W. F. Rossman, Assr. to American Zinc, Lead, and Smelting Co. U.S.P. 1,424,120, 25.7.22. Appl., 16.5.21.

A refractory material for zinc retorts and the like consists of plastic clay mixed with finely ground silica and ground grog in about equal proportions.
—A. R. P.

Kiln; Continuous chamber —— *for burning ceramic wares, lime, dolomite, etc.* H. Koppers. G.P. 349,951, 22.8.19.

A continuous chamber kiln is provided with flues leading from the top of one chamber to the sole of the next, to supply cold air, with trace holes through which the hot gases pass from the sole of one chamber to that of another, and with sand ducts for sealing the trace holes with sand. Any surplus hot air gives up its heat to a regenerator, which is then used for warming the gases which have been previously cooled to facilitate purification. In burning lime, dolomite, etc., the waste gases are used to preheat the freshly-set chambers and the incoming heating gases, the air supply being preheated by the hot calcined material.
—A. B. S.

Kiln; Continuous down-draught chamber ——. A. W. F. Weyers. G.P. 349,952, 22.4.20.

A continuous down-draught chamber kiln has a series of gas producers in each of the partition walls between the chambers, and the air or mixture of air and hot gases is supplied in part to the grate of the producer, and in part upwards around the walls of the producers. The gas-producers and air-flues are arranged alternately across the kiln. In the lower part of each producer are poke holes, so that air may be freely admitted through these holes, or the production of gas may be regulated by closing the holes with ashes; this arrangement permits adequate regulation of the temperature without the use of dampers.—A. B. S.

Sheet glass; Method of and apparatus for drawing ——. W. J. Mellersh-Jackson. From The Libbey Owens Sheet Glass Co. E.P. 184,053, 28.7.21.

Kiln; Tunnel ——. A. McD. Duckham and A. T. Kent. U.S.P. 1,424,560, 1.8.22. Appl., 27.2.22.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast-furnace practice; The bases of modern ——. A. K. Reese. Iron and Steel Inst., Sept., 1922, [Advance proof.] 35 pages.

A description of the bases of modern blast-furnace practice under the headings: preparation of materials; furnace design; auxiliary equipment; method of operation. An essential feature of the modern method of operation is the supply of a uniform volume of blast irrespective of furnace pressure or resistance.

Cast iron; Growth of grey —— during repeated heatings and coolings. T. Kikuta. Sci. Rep. Tôhoku Imp. Univ., 1922, 11, 1—17.

The rate of leakage of air into a hollow cylinder of grey cast iron heated repeatedly to a temperature of 910°—960° C., increased up to 60 heatings and afterwards decreased. For less than 20 heatings the leakage rate was nearly constant with rising temperature up to 900° C.; with more than 34 heatings the rate first decreased and afterwards increased with rising temperature. It is improbable that growth during repeated heating and cooling through the A1 range is caused by the pressure of occluded gases, though at higher temperatures this may be the cause. From measurements of the density of specimens after different heat treatments and of thermal dilatation during continuous heatings and coolings, the following explanation of the growth of grey cast iron is given. During the first heating through 700°—800° C., growth is partly due to the decomposition of cementite. During repeated heating and cooling through the A1 range *in vacuo*, growth ensues from the formation of numerous fissures in the neighbourhood of graphite flakes, due to differential expansion of different micro-portions of the metal. Under oxidising conditions oxides are formed and fill the fissures during the Ar1 transformation, thus accelerating the growth. The effect of the oxidation is therefore only indirect. The growth of white cast iron is almost completed during the first heating to 800° C., being due to the extent of about one-third to the decomposition of cementite and to the extent of about two-thirds to the minute fissures caused by irreversible expansion of different micro-portions.
—T. H. Bu.

Cast iron; Influence of cross-sectional area of the test-piece on [the results obtained for] the tensile and bending strength of ——. P. Oberhoffer and W. Poensgen. Stahl u. Eisen, 1922, 42, 1189—1192.

Determinations of the bending and tensile strengths of test-pieces of cast-iron of different diameters cut from the same casting gave figures that increased rapidly to a constant value when the diameter of the test-piece exceeded 20—25 mm. The results are discussed from the point of view of the distribution of the graphite inclusions and the phosphide network in the structure of the metal.
—A. R. P.

Boiler plate after cold work or work at blue heat. H. J. French. Chem. and Met. Eng., 1921, 24, 211—216.

Mechanical tests on fire-box plate which had been reduced 6·25% and 12·5% respectively by light rolling at 295° C. showed that the increase in strength of the metal was about twice that produced by similar cold reduction. Above this temperature the increase due to blue deformation was somewhat less than from cold rolling. The maximum strength of the steel subjected to 6·25% reduction was obtained at 295° C., the strength-temperature curve being similar to that of cold-worked steel. The proportional limit resulting from blue strain (6·25% reduction) was greater than that obtained from a cold reduction twice as great. Elongation and reduction in area decreased to a minimum at about 200° C., and increased to high values at 460° C., with a marked increase between 295° and 410° C. Annealing for 30 mins. at 700° C. completely removed the effect of blue deformation. The general form of curves showing tensile strength in a transverse direction was similar to those for longitudinal tests, but the limit of proportionality did not increase with the first rise in temperature in the transverse test specimens. Repeated overstrain at blue heat whether at constant or increasing loads raised the apparent limit of proportionality, which in one case increased from 15,000 to 56,000 lb. per sq. in. Such deformation did not, however, appear to modify other mechanical properties when the specimen was broken finally. Heating steel overstrained at blue heat, to above the Ac1 point, or allowing a period of rest, restored the apparent elasticity of the metal at ordinary temperature. The increased strength of steel due to blue deformation was not a skin or surface effect.—C. A. K.

Carbon tool steels; Black fractures in ——. A. W. F. Green. Chem. and Met. Eng., 1922, 27, 256—267.

Certain ingots of a hyper-eutectoid tool steel made by the crucible process to the following composition, 1·16% C, 0·30% Mn, 0·024% P, and 0·25% Si, showed on fracturing a considerable black area usually concentric with the contour of the ingot and containing a small white area of the same shape in the middle. These formations were noticed only after the steel had been annealed to cause the cementite to assume a spheroidal form, *i.e.*, at a temperature just below the Ac 1, 2, 3, range. Chemical analysis of black and white parts gave identical figures, but the Brinell hardness of the black part was only 95 as compared with 170 for the white part. Further annealing of the material at a low temperature caused the formation of further black areas, while quenching from 770° C. had the same hardening effect in both black and white areas. Photomicrographs and a heating and cooling curve are given. —A. R. P.

Chromium steels; Resistance to corrosion of various types of ——. H. S. Rawdon and A. I. Krynitsky. Chem. and Met. Eng., 1922, 27, 171—173.

Details are given of the corrosion effects produced in samples of chromium- and nickel-steels when exposed to the action of dilute hydrochloric acid, and when submitted to a weathering test consisting in immersing the steel in distilled water just below the surface and exposing to the atmosphere. Pure iron and steels of low chromium content were much more resistant to hydrochloric acid than those of high chromium content. In the weathering test the general order of resistance to corrosion was reversed. Hardened samples were considerably more resistant to acid attack and to weathering than annealed samples. Steels containing considerable nickel were most resistant to acid attack. Steels of high chromium content showed the least corrosion effects in the weathering test, while steels of low chromium content were more resistant than carbon steel or pure iron. Adhering patches of oxide had a marked effect in accelerating the corrosion due to weathering. A steel containing a high nickel and chromium content (20·12% Ni, 7·68% Cr) was least attacked by acid and was very resistant to atmospheric corrosion.—J. S. G. T.

Gold precipitation by zinc dust in conjunction with de-aeration of solution at Modderfontein B [*Transvaal*]. S. Newton and L. L. Fewster. J. Chem. Met. Soc. S. Afr., 1922, 22, 249—257.

The cyanide solution from the leaching tanks is passed through three clarifiers in parallel and the clear liquid is then pumped into precipitating tanks where a uniform feed of 90-mesh zinc dust is mechanically sprinkled into the solution. The whole is then pumped through precipitation presses where the whole of the solution at some period comes into contact with layers of fine-grained precipitant, thus ensuring complete removal of the gold. The effluent from the presses, containing 0·02 dwt. of gold per ton, is used for washing the sands after leaching. The press-cake is cleaned with acid, smelted in Tavener furnaces and the product is cupelled. To obtain the best results in the precipitation process with the minimum zinc consumption it was found necessary to de-aerate the solution by passing it through a vessel where it is subjected to a vacuum of 22 in. In this case the zinc consumption is so reduced that the gold is precipitated in a slimy state, so that it was found necessary to add a filtering medium such as coke, sawdust, or kieselguhr, whereby a sufficiently "dry" cake for handling was obtained. Lead nitrate solution is added to the liquor from the clarifiers to assist in collecting the gold; added in this way less zinc is required than by the older method of allowing lead nitrate solution to drip continuously into the precipitating tank.—A. R. P.

Silver; Density of molten ——. R. Hoffmann and W. Stahl. Metall u. Erz, 1922, 19, 357—358.

The average coefficient of expansion of silver between t_1° C. and t_2° C., the latter temperature being above the melting point, is given by the equation $K=(V_2-V_1)/(V_1t_2-V_2t_1)$ where V_1 and V_2 are the volumes of the same mass of silver at t_1° and t_2° C. respectively. Using this relation and representing the specific gravity of silver at t_1° and t_2° C. respectively by S_1 and S_2, the specific gravity of molten silver at any temperature may be calculated by means of the equation $S_2=S_1(1+Kt_1)/(1+Kt_2)$. The values as obtained for 1000°, 1025°, and 1050° C. are 9·653, 9·633, and 9·613 respectively. —A. R. P.

Ferro-titanium; Rapid [*method for the*] *complete analysis of* ——. C. Grandjean. Chim. et Ind., 1922, 8, 46.

One gram of the powdered alloy is roasted for 15 min. and the product is fused with 25—30 g. of sodium carbonate in a nickel crucible. The melt is extracted with water, the insoluble residue collected on a filter and well washed with dilute sodium carbonate solution. The filtrate is used for the determination of silicon and aluminium, and the residue is dissolved in hydrochloric acid. The solution is treated with ammonia until a small white precipitate just fails to redissolve, then boiled with 50 c.c. of sulphur dioxide solution for 15 min. to precipitate the titania, which is filtered off, ignited, and weighed at TiO_2. It must be tested for iron by ammonium sulphide in ammoniacal tartrate solution and a correction applied corresponding to the amount of iron found. The filtrate from the titania is used for the determination of iron, manganese, calcium, and magnesium by the usual methods.—A. R. P.

Copper; Study of the "hydrogen sickness" of ——. O. Bauer and Vollenbruck. Z. Metallk., 1922, 14, 296—299.

In rolling cast copper bars into sheets it is usual to heat them to the rolling temperature by causing a gas flame to play on the upper surface of the bar. In the case of bars containing cuprous oxide cracks and fissures often develop during the subsequent rolling and it is shown that the cause of these cracks is most probably the reduction of the cuprous oxide to metallic copper by the hydrogen in the gas with the simultaneous formation of steam in the metal under considerable pressure, this steam forcing its way out and producing a crack. During the rolling this crack becomes filled with fresh quantities of cuprous oxide and further failure of the metal results. It was found that if the metal was annealed in an atmosphere free from hydrogen before rolling, no trouble was experienced in working it.—A. R. P.

Copper; Corrosion of —— *by salt solutions.* W. Müller. Z. Metallk., 1922, 14, 286—295.

The corrosive action of sea water and of its contained salts, sodium chloride, magnesium sulphate, magnesium chloride, and calcium sulphate, on annealed copper and on copper that has been subjected to different degrees of rolling, was studied over considerable periods and with differing strengths of solution, and the results are reproduced in a series of tables and graphs. The general effect of the chlorides is much more marked than that of the sulphates; sodium chloride is the most active corroding agent, causing after 48 hrs. a considerable deposit of basic copper chloride which is readily detached and so does not protect the metal from further attack. The resistance to corrosion by sodium chloride is decreased by rolling the metal, but rolling increases the resistance towards sea water, magnesium sulphate, and magnesium chloride.—A. R. P.

Aluminium; Solubility of gases in ——. J. Czochralski. Z. Metallk., 1922, **14**, 277—285.

Molten aluminium does not begin to dissolve any of the common gases until about 900° C., but at higher temperatures considerable amounts may be dissolved, and retained in the form of minute blowholes in the solid metal. The following table shows the amount of gas, in volumes per cent., dissolved at the high temperature and retained by the solid metal at ordinary temperatures:—

°C	N_2	O_2	Air	CO	CO_2	SO_2	H_2	Town gas
1200	0·4	2·5	1·3	1·3	2·5	5·4	6·5	5·5
1500	3	12	6	8	12	7	15	12·5

In the case of the first six gases very small amounts of the absorbed gases combine with the metal with formation of aluminium nitride (AlN), oxide, carbide (Al_3C_4) or sulphide, and the metal structure shows characteristic inclusions of these constituents. The mechanical properties of the metal after treatment with any of the above gases showed practically no change, but in all cases blisters and splitting of the edges occurred during rolling. The most suitable temperature for rolling metal containing many gas-pores was found to be between 300° and 350° C. —A. R. P.

Aluminium and alumina; Determination of small quantities of sodium in ——. R. Geith. Chem.-Zeit., 1922, **46**, 745.

Aluminium cannot be separated completely from sodium salts by precipitation with ammonia, as a little alumina invariably remains dissolved, probably in a colloidal form. The following electrolytic method gives good results: 2 g. of the metal is dissolved in a minimum of hydrochloric acid and any silica and copper removed by filtration. The clear liquor is transferred to a bottomless cylindrical vessel floating in a tray of mercury at the bottom of a glass trough which is filled with dilute, neutral sodium chloride solution to about ½ of the height of the vessel containing the assay. A carbon anode is suspended in the assay solution and a current of 0·15 amp. at 3·5 volts is passed between the carbon and the mercury for 2—3 hrs., whereby all the sodium is deposited in the mercury as amalgam and passes out of the cell, the sodium dissolving in the weak salt liquor as sodium hydroxide which may be determined volumetrically. Four nickel wires are suspended in the mercury outside the cell, forming a couple, which ensures rapid solution of the sodium in the chloride liquor, and the gases evolved from the electrolysis are removed by suction as fast as they are formed. The determination of sodium salts in alumina, such as that prepared for the manufacture of aluminium, is effected by evaporating 1 g. of the material 2 or 3 times to dryness with sulphuric acid, extracting the residue with water and electrolysing the filtered extract with 0·2—0·3 amp. at 4—5 volts, using a platinum anode.—A. R. P.

Tin; Simple and rapid estimation of —— in bearing metal and like alloys. J. Nagel. Chem.-Zeit., 1922, **46**, 698.

From 0·5 to 1·0 g. of the alloy is introduced as filings into a 300 c.c. titration flask covered with a watch-glass, together with 2·3 g. of potassium chlorate and 100—150 c.c. of concentrated hydrochloric acid, and heated as long as chlorine is evolved. The solution is then diluted with 30 c.c. of distilled water, and 5—7 g. of sodium chloride added to raise the boiling point. A nickel plate about 3 mm. thick and 10 sq. cm. area, bent into the form of a ring, is then placed in the liquid and the flask heated for about 1 hr. Stannic chloride is reduced to stannous chloride, whilst antimony is precipitated in flakes upon the nickel. The liquid is then boiled to expel air and a current of carbon dioxide passed through it while cooling. The stannous chloride is then titrated with iodine. The method is accurate in presence of antimony, copper, and lead.—C. I.

Strontium-lead alloys; Constitutional diagram of ——. E. Piwowarsky. Z. Metallk., 1922, **14**, 300—301.

Lead and strontium are practically immiscible in the solid state. The compound, Pb_3Sr, containing 12·35% Sr melts at 676° C., and alloys containing less strontium begin to deposit crystals of this compound at progressively lower temperatures situated on a parabolic curve convex to the axis of temperature. In all the alloys a break occurs in the cooling curve at 327° C., indicating the presence of a eutectic. Alloys containing less than 12·35% Sr show dendritic masses of cubo-octahedral crystals of the compound disseminated throughout a ground mass of pure lead.—A. R. P.

Metals; Determination of gases in ——. H. L. Simons. Chem. and Met. Eng., 1922, **27**, 248—249.

The metal is dissolved in mercury and the evolved gases are collected first in a Geissler tube for spectroscopic examination, then in the usual gas apparatus for quantitative analysis. The apparatus consists of a dissolving flask connected with a Liebig condenser by means of a ground glass stopper, the upper end of the condenser being bent at right angles and closed with a stopcock. Between this and the Toepler pump a three-way stopcock is introduced connecting also with a source of pure dry oxygen. Between the two stopcocks a T-tube connects with the Geissler apparatus and between the condenser and the dissolving flask a second T-tube connects with the mercury reservoir. The apparatus is first exhausted, then filled with oxygen and again exhausted. Oxygen is once more admitted, the sample placed in the flask and all the joints closed with mercury seals. After again exhausting till a spark refuses to pass in the Geissler tube, the mercury is allowed to run on to the metal and heated until the sample dissolves. After cooling, the stopcock above the condenser is opened and the evolved gas examined in the Geissler tube, then transferred to the ordinary gas-analysis apparatus. —A. R. P.

Reversible expansion of silica. Houldsworth and Cobb. *See* VIII.

Patents.

Steel; Process for the production of basic ——. Usines Métallurgiques de la Basse-Loire (Soc. Anon.). E.P. 163,693, 28.4.21. Conv., 18.5.20.

Pig iron containing more than the normal quantity of silicon is introduced into a converter which already contains a highly oxidised ferruginous slag together with all the lime required for the final operation. The slag bath oxidises the silicon immediately the molten iron is added, and undue projection during blowing is prevented.—C. A. K.

[Iron] ores; Process of reducing ——. Trent Process Corp. Assees. of W. E. Trent. E.P. 169,950, 13.4.21. Conv., 4.10.20.

Iron ore is ground with coal and the mixture heated to 300°—400° C. to obtain the maximum yield of oils and partially reduce the iron oxide to a compound which is magnetic or to metal. The material is then subjected to magnetic separation to remove the iron-bearing material in substantially pure form. The non-magnetic portion is mixed with water and part of the oil obtained in the first step to separate the carbonaceous material from the gangue constituents of the ore, and the resulting oily mass of carbon is mixed with the magnetic material and the mixture is smelted to give pure iron or, if desired, steel.—A. R. P.

Steels and the like; Annealing and hardening high and low carbon ——. F. J. Parr, J. Mawer, and W. Painton. E.P. 182,825, 3.1.21.

Steel is embedded in a material which is produced by artificially drying plants of the pea and bean varieties, and adding powdered charcoal, and is then annealed or hardened as usual.—C. A. K.

Iron or steel surfaces; Treatment for obviating the rusting or oxidation of ——. W. B. Brunskill. E.P. 182,988, 10.5.21.

Iron or steel is treated with a boiling solution of zinc di-hydrogen orthophosphate (about 1%), the article being in contact with metallic zinc and placed on a zinc support. Zinc dust may be added to the solution to give many points of contact. A hard grey coating of zinc is deposited on the metal with a minimum quantity of iron phosphate, and the colour of the coating is not altered when the deposit is permeated by oil. The preparation of the solution is described in E.P. 169,884 (J., 1921, 854 A).—C. A. K.

(A) *Iron; Treating ore to produce pure* ——. (B, C) *Process of extracting iron from its ores.* (D) *Process of extracting metals from their ores.* A. J. Moxham. U.S.P. 1,420,127—30, 20.6.22. Appl., (A) 8.1.19, (B, C) 5.4.19, (D) 2.11.18. (D) Renewed 13.12.21.

(A) Oxide of iron present in the ore is reduced and the iron is purified by electrolysis while the reduced material is in the form of fine particles in good conductive contact with each other. (B) An iron solution is subjected to electrolysis to separate the iron, the acid set free being caused to combine with a base other than iron, by which means re-solution of the iron is prevented. (C) Iron is dissolved from its ore with hydrochloric acid. Sulphuric acid is added, setting free the hydrochloric acid for re-use and forming iron sulphate, from which the iron is separated by electrolysis. (D) A metallic constituent (iron) is dissolved from ore and the gangue separated from the solution, which is subjected to electrolysis to separate the pure metal.—T. H. Bu.

Steel; Manufacture of open-hearth ——. H. C. Ryding and A. W. Allen. U.S.P. 1,423,031, 18.7.22. Appl., 6.7.17.

A complete charge of molten blown metal is introduced into a bath of highly heated complete oxidising slag containing lime in an open-hearth furnace. An entirely new slag is used for each heat of metal.—C. A. K.

Silicon-manganese-chrome steel; Method of producing ——. G. Gufstafson, A. A. Jungmarker, and K. A. Caspersson. U.S.P. 1,423,847, 25.7.22. Appl., 17.3.21.

A charge of molten basic open-hearth steel is treated successively with ferromanganese and a previously melted decarburised alloy of ferrochrome and ferrosilicon.—C. A. K.

[Iron;] Process and apparatus for the operation of cupola furnaces [for smelting ——*]*. H. Koppers. G.P. 348,384, 29.3.19. Addn. to 341,637. (*Cf.* U.S.P. 1,357,781; J., 1921, 16 A, and G.P. 343,944; J., 1922, 470 A.)

The molten iron and slag are allowed to flow away slowly from the furnace so that the surface of the slag is maintained in the neighbourhood of the tuyères, whereby the carbon that is dipping in the slag attains a very high temperature, rapidly reduces the oxides therein and causes the sulphur to combine readily with the lime to form calcium sulphide; owing to the low wind pressure in the cupola, the slag readily flows away while a simultaneous evolution of a part of the contained gases takes place. The collecting tank furnace for the molten iron is provided with a regenerator which is heated by means of the gases evolved through the slag overflow. In this way the metal is raised to such a temperature as to allow of the necessary additions of alloying elements according to the use to which the metal is to be put.—A. R. P.

Iron; Process for making —— *capable of being hardened.* R. Walter. G.P. 353,623, 6.11.18.

Soft or cast iron is rendered capable of being hardened by the addition of small quantities of boron; the effect is noticeable with 0·001% B. Boron increases the mechanical strength and causes a decrease in the grain size of the metal.—A. R. P.

Refractory oxides; Method of producing high temperatures for reducing ——. A. Pacz. E.P. 160,427, 18.3.21. Conv., 19.3.20.

An alloy of the rare earth elements and aluminium is produced by reducing the double sodium fluoride of the rare earth element with aluminium over a bath of molten aluminium according to E.P. 160,426 (J., 1922, 637 A). The resulting alloys are broken up and used instead of aluminium in the alumino-thermic reduction of refractory oxides, such as those of zirconium or boron. The temperature of the reaction is much greater than when aluminium alone is used and good yields of alloys with a high content of the refractory element are obtained.—A. R. P.

Furnace; Open hearth ——. Miami Metals Co. Assees. of G. L. Danforth. E.P. 182,399, 7.12.21. Conv., 26.9.21.

In a reversible open-hearth furnace dampers are introduced between the air and fuel ports and the furnace chamber which enable the effective passage area between the ports and the melting chamber to be varied. The air ports are situated on each side of the fuel port, so that the air streams are directed by the dampers towards the central fuel stream. The dampers are removable from the outgoing end of the furnace, and may be introduced through the furnace roof or laterally from each side.—T. H. Bu.

Blast furnaces and the like; Process for sealing cracks in the linings of ——. T. Kennan. U.S.P. 1,423,332, 18.7.22. Appl., 14.1.22.

The stock level in the furnace is raised above the level of the crack and a flow of air is concentrated in the material adjacent to the crack so that fluxing occurs and molten material enters and fills the crevice.—C. A. K.

Light metals [e.g. magnesium and aluminium alloys]; Process for recovering —— *from scrap.* Chem. Fabr. Griesheim-Elektron, and A. Beielstein. E.P. 182,948, 15.4.21.

Magnesium or aluminium or their alloys, in the form of scrap mixed with non-metallic impurities, such as oxides of the metals, sand, or graphite, are introduced into a heated pot fitted with a stirrer carrying a number of arms. As the metal melts down a quantity of anhydrous magnesium chloride, approximately equal in weight to the impurities present, is slowly stirred in, and stirring is continued until the liquid chloride has disappeared from the surface of the metal and the impurities have agglomerated into nodules which absorb the chloride. At this stage stirring is stopped and the agglomerated masses of impurity sink to the bottom of the pot carrying with them all the magnesium chloride added. The temperature is then raised to that required for pouring and the purified metal is poured away from the impurities. Magnesium chloride may be replaced by carnallite or may be made *in situ* by passing chlorine into the melting metal.—A. R. P.

Mineral particles of different degrees of specific gravity; Separating mixed ——. *Differential flotation separator.* W. H. Peck. U.S.P. (A) 1,420,138 and (B) 1,420,139, 20.6.22. Appl., 20.7.21.

(A) The materials are subjected to the floating action of an aerated emulsion of water, oil, and a flotation reagent, and to the action of centrifugal force of such intensity that the heavier particles are precipitated through the emulsion while the lighter particles are floated by the emulsion. (B) A vessel containing a liquid flotation medium is rotated and is so arranged that during operation the flotation medium presents a substantially unobstructed flotation surface facing the direction of the axis of rotation. On feeding in particles of different specific gravities, the energy of the flotation medium and the centrifugal energy of the particles act in opposite directions. Means are provided to supply pneumatic agitating currents from the bottom of the vessel at the periphery.—T. H. Bu.

Pulverulent material; Concentrating ——. F. Ondra, Assr. to Concentrators, Ltd. U.S.P. 1,421,984, 4.7.22. Appl., 28.1.20.

The material is mixed with a fluid under pressure and projected in a stream inclined at an angle to the vertical. The particles are collected in predetermined zones as they fall due to their weight. Fractions of gangue and mineral particles of the same weight, but varying as to size, are thus obtained, and are subsequently separated according to size of particles.—T. H. Bu.

[Lead and iron sulphide] ores; Concentration of —— *by flotation.* G. E. Sheridan and G. G. Griswold. U.S.P. 1,421,585, 4.7.22. Appl., 13.1.21.

The ore is treated with a cyanide and an alkaline salt and subjected to a flotation operation. Lead sulphide is recovered in large part in the resulting froth, the flotation of iron sulphide being largely inhibited.—T. H. Bu.

Metals [e.g. copper]; Process for recovering or dissolving ——. H. Bardt, Assr. to Sociedad Hidro-Metalurgica. U.S.P. 1,423,069, 18.7.22. Appl., 17.9.21.

An ore, matte, alloy or cupriferous waste is dissolved in a mixture of sulphuric and nitric acids, in the presence of a catalyst, under a pressure produced by electrolysing the solution in a closed vessel.
—A. R. P.

Alloy and method of producing same. C. A. Laise, Assr. to General Electric Co. U.S.P. 1,423,338, 18.7.22. Appl., 13.9.20.

An alloy containing a predominating amount of tungsten, together with gold and about 0·1% of vanadium is claimed.—A. R. P.

Arc welding; Electrical ——. J. Churchward, Assr. to Wilson Welder and Metals Co. U.S.P. 1,423,914, 25.7.22. Appl., 14.1.20. Renewed 3.2.22.

An electrode made of tungsten is used for electric arc welding.—C. A. K.

Autogenous cutting and welding; Process for ——. Rheinisch-Westfälische Kupferwerke A.-G. G.P. 353,597, 18.8.20.

An extremely hot flame is obtained by introducing in a finely divided form into the oxygen stream solid or liquid substances, such as manganese, calcium, aluminium or wood charcoal, which have a high heat of combustion. The process is suitable for removing sows from blast-furnaces by introducing into the taphole a mass of finely divided wood-charcoal and playing a stream of oxygen on to it, whereby the sow is rapidly melted away.
—A. R. P.

Brass; Process for the manufacture of ——. P. Dutoit, Assr. to A. Boever. U.S.P. 1,423,922, 25.7.22. Appl., 10.9.19.

Zinc and copper are introduced, a little at a time, into a bath of a molten salt the sp. gr. of which is intermediate between that of the alloy and that of any slag formed, so that the latter rises to the surface and may be readily removed.—A. R. P.

Zinc; Process for the preparation of pure —— *from crude zinc.* Metallbank und Metallurgische Ges. A.-G. G.P. 301,727, 16.10.14.

Crude zinc is slowly redistilled from a retort the depth of which is several times as great as the diameter at the surface of the metal, *e.g.*, the Kipp retort in which rich zinc skimmings are usually distilled. The retort is charged with metal up to its narrow upper part and heated just above the distillation temperature, fresh zinc being added as the purified metal distils off, while the lead-rich alloy, containing any silver present, sinks to the bottom and is removed from time to time. The process is more efficient the smaller the surface from which the zinc distils.—A. R. P.

Zinc and other volatile metals; Process and apparatus for recovering —— *from ores etc. Process for the reduction of [ores of] zinc and other volatile metals and for calcining marble, dolomite, magnesite and the like.* H. Koppers. G.P. (A) 350,521, 17.4.18, and (B) 351,352, 29.5.18.

(A) The distillation is carried out in two stages; in the first the more volatile impurities are removed by distillation and in the second comparatively pure zinc. The process is carried out in retorts each separated from the others by double heating-walls and each connected with its own regenerator so that each is a separate unit. Each retort is provided with two gas-collecting flues arranged in such a manner that one may be used for the gases evolved in the first stage (steam, carbon dioxide, carbon monoxide, and cadmium vapour) and the other for collecting the zinc. The mixture of zinc vapour and carbon monoxide from the latter is passed up a long column with a cooler at the upper end so that liquid zinc falls down through the column of rising vapours, and a product is obtained which consists of zinc in the purest possible form. In order to obtain good results the vapour must pass into the rectifier at the highest possible temperature; the column is therefore built directly above the furnace. (B) The ore charge is made into large prismatic briquettes which are packed into the centre of the furnace chamber and the space between the walls and the charge is filled with carbon bricks so that the whole charge is enveloped in carbonaceous reducing agent, thereby protecting the walls of the furnace from any fluxing action by the constituents of the charge.

For calcining marble, magnesite, and the like, the material is charged into a brick container of the same shape as the furnace and this is pushed into the latter, heated as desired and withdrawn with the residue at the end of the operation.—A. R. P.

Zinc, calcium, aluminium, silicon and the like; Process for the electrothermic recovery of ——. W. Neumann. G.P. 351,411, 2.10.20.

Elements such as zinc, calcium, and the like having boiling points near to the temperature at which their oxides are reduced, are obtained by smelting the ore mixture in an electric furnace and removing the gases from the top of the furnace and introducing them again at the bottom while the ore charge falls obliquely through the furnace. In this way a constant gas pressure is obtained, and the gases are forced through the charge, facilitating reduction and, in the case of zinc, reducing appreciably the amount of zinc dust formed. —A. R. P.

Zinc; Apparatus for the electrolytic production of ——. E. Langguth. G.P. 352,735, 3.11.20.

Zinc sulphate is electrolysed in a cell with a lead anode separated from the cathode by a porous partition which does not reach to the bottom of the cell. The anode or the cathode, or both, may be surrounded by porous pots having openings at the bottom. With this arrangement any solid particles that fall from the anode fall to the bottom of the cell and may easily be removed.—A. R. P.

Electrolytic cell for the electrolytic treatment of metals and ores. A. Barth. G.P. 351,408, 5.5.21.

A number of metal plates, inclined at a moderate angle, are arranged in a vessel upon a frame which is easily removable. The lowest plate serves as anode. the current passing to the material placed on the plate. The lower side of the next plate in the series acts as cathode, and the upper side, covered with material to be treated, acts as anode, this sequence being continued throughout the series of plates, the last of which serves as cathode. Metals or ores can in this manner be treated with the minimum of electrolyte in the smallest practicable vessel. Gaseous by-products and the concentrated solution are recovered automatically in a manner which prevents the gases liberated interfering with the process of solution, and secures that the solution when formed is not subjected to the further action of the current.—J. S. G. T.

Gold, silver, copper, etc.; Process and apparatus for the electrolytic separation of —— *from alloys.* B. Waeser. G.P. 351,410, 17.3.21.

Alloys containing chiefly gold, silver, and copper, together with smaller amounts of the platinum metals, lead, tin, iron, and other base metals, are electrolysed in a concentrated solution of copper sulphate and nitrate containing a small excess of acid. The electrolysis is carried out in a divided cell in which the electrodes are arranged vertically. The reaction products from the anode compartment are continuously removed together with suspended anode slime and replaced continuously by a stream of the catholyte. The solution removed from the anode chamber is filtered into a drum-shaped precipitating tank, where it is treated with copper to remove silver and less electro-positive metals, which by vigorous agitation are detached from the copper and separated from the solution. The anode may consist of the original alloy in the form of plate, sheet, rods, turnings, or other scrap. —A. R. P.

Aluminium alloys; Manufacture of ——. S. Henlein and E. Motkenlin. G.P. 351,739, 30.3.21. Addn. to 314,999 (J., 1920, 270 A).

The tin content of the alloys specified in the chief patent is kept within the limits 2 and 4%. The resulting alloys may be worked cold or hot and rolled or drawn into wire.—A. R. P.

Cerium and its alloys; Process for coating —— *with other metals.* E. Merck, Chem. Fabr. G.P. 351,750, 23.8.21.

Cerium or one of its alloys is coated with aluminium, magnesium, or zinc by heating it to a temperature below its melting point and then applying the coating metal, preferably in a finely powdered form, either alone or mixed with carbon, sand, or the like, and continuing the treatment for a considerable time.—A. R. P.

Galvanised or tinned metal; Production of coloured coatings on ——. R. Kirchhoff. G.P. 351,981, 31.8.18.

The articles are treated with a paste made from a solution in dilute acids of ferric oxide, or minerals containing it, mixed with sufficient specular iron ore, stibnite, or zinc white to give the articles the shade of colour desired. Graphite may, if desired, be incorporated in the coating mixture. The coatings obtained are resistant to weathering and dirt does not adhere to them.—A. R. P.

Alloys of lead with light metals and cadmium. W. Stockmeyer and H. Hanemann. G.P. 352,471, 8.2.16.

Small quantities of cadmium, not exceeding 5%, reduce the brittleness without deleteriously affecting the chemical resistance of lead alloys containing sodium, magnesium, calcium, and the like. Small quantities of copper may be added to increase the hardness.—A. R. P.

Copper containing bismuth; Process of rendering —— *suitable for technical use.* K. L. Meissner. G.P. 352,685, 6.3.21.

Molten copper containing bismuth is treated with a small quantity of a metal of the alkali, alkaline-earth or rare earth group together with at least 3% of manganese or nickel. The added metals form compounds with bismuth which do not segregate round the copper crystals and cause red-shortness as bismuth alone does.—A. R. P.

XI.—ELECTRO-CHEMISTRY.

Carbon-electrode industry; Technology of the ——. C. L. Mantell. Chem. and Met. Eng., 1922, 27, 161—164, 205—210.

The characteristics of the raw materials entering into the manufacture of carbon electrodes are briefly reviewed, and the calcination process discussed critically, various forms of electric and gas heated calciners being described. In general, a denser coke or calcined product is produced in electric calciners. Gas-fired units have lower operating costs. In electric calciners, there is a tendency to graphitise some of the charge, so that a calcined product of lower resistivity is produced than is possible with gas retorts.—J. S. G. T.

Carbon-electrode industry; Technology of the ——. IV. Grinding, mixing, moulding, and extrusion. C. L. Mantell. Chem. and Met. Eng., 1922, 27, 258—264.

The calcined materials, coal, coke and petroleum coke, as discharged from the calciner are ground from 3 in. down to 1 in. size by means of corrugated rolls equipped with reciprocating plate feeders and then further ground in roller pulverisers and the fines separated by air levigation. The product is then graded and a mixture of the desired sizes of particles is made into a stiff paste with the necessary binder, tar or pitch, in a steam-heated, mechanically stirred mixing vessel. The mass is discharged from the mixers into presses where it is either pressed or extruded into the desired shape, the latter method being used for small electrodes. A description of several presses and of a typical installation is given, and the factors governing the production of good quality electrodes and reasons for obtaining faulty carbons are discussed.—A. R. P.

Graphite; Researches on natural and artificial ——. K. Arndt and F. Körner. Z. angew. Chem., 1922, 35, 440—443.

The specific resistance of rods pressed from different varieties of natural and artificial graphite has been determined. The results show that the specific electrical resistance of graphite depends principally on the grain-size and ash content, while the shape of the grains has also a slight influence. The resistance increases with increasing ash content and decreases with increasing size of the grains. In the case of graphitised electrodes the resistance depends chiefly on the volume of the pores and on the actual graphite content, a decrease in the former and an increase in the latter reducing the resistance. A curve has been constructed for the specific resistance of mixtures of graphitised and ungraphitised gas carbon compressed into rods, from which, by observing the resistance of a graphitised anode of unknown composition, a rough idea of the amount of contained graphite may be obtained. The resistance of a number of mixtures of graphite and powdered manganese dioxide, such as are used in battery anodes, is represented graphically; the addition of the manganese dioxide very slightly increases the resistance up to a content of 50—60%, after which an exceedingly rapid increase is observed.—A. R. P.

Platinum film electrodes; Preparation and applications of ——. A. Eilert. Z. angew. Chem., 1922, 35, 445—446, 452—455.

Details are given of the preparation of platinum film electrodes suitable for use in electro-analysis, conductivity measurements, and titration processes, and for use as hydrogen electrodes. The films are deposited upon the external surface of glass tubes by heating a solution of "Glanzplatin Ia" (Koehler, Leipzig) with which the tubes are coated. (According to Kundt a "Glanzplatin" solution is composed of 3 g. of platinum chloride dissolved in 10 c.c. of absolute alcohol and treated with 30 c.c. of a concentrated alcoholic solution of boric acid and twice the quantity of a mixture of Venetian turpentine and lavender oil.) Only in the case of film electrodes used in the electro-analysis of metals do the films require periodical renewal. A simplified method of electrometric titration of solutions of salts of weak acids is described.—J. S. G. T.

Conductivity of glass. Bush and Connell. *See* VIII.

Patents.

Conductors for making electrical connection with mercury. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 183,683, 30.6.21.

A wire of oxidisable refractory metal, *e.g.*, tungsten, molybdenum, etc. is tipped with iron or nickel or other metal, the oxide of which may be reduced by hydrogen. The wire is sealed into a glass envelope and the tip makes contact with mercury.—J. S. G. T.

Ozone generator. H. B. Hartman, Assr. to Electric Water Sterilizer and Ozone Co. U.S.P. 1,423,658, 25.7.22. Appl., 24.1.20.

An ozone generator comprises a casing consisting of separable sections provided with vertical radial ribs and central chamber-forming members, and a generating unit consisting of spaced dielectric members together with an intermediate electrode disposed between the members and the separable sections. A terminal plug is arranged in one of the chambers, and electrical connexion is made at the central part of the electrode of the generating unit.—J. S. G. T.

Electric storage battery. H. Bardt, Assr. to Soc. Hidro-Metalurgica. U.S.P. 1,425,163, 8.8.22. Appl., 17.9.21.

See G.P. 329,787 of 1919; J., 1921, 267 A.

XII.—FATS; OILS; WAXES.

Liver oils; The sulphuric acid reaction for ——. J. C. Drummond and A. F. Watson. Analyst, 1922, 47, 341—348.

The substance present in liver oils which is responsible for the well-known purple coloration with sulphuric acid was found in the following species: man, horse, ox, pig, cat, monkey, rabbit, guinea pig, chicken, duck, pigeon, rat, mouse, frog, shark, cod, haddock, ling, coal fish, dog fish, sprat, and skate. The substance appears to be a normal constituent of the liver and is not derived from the bile or from products of autolysis or putrefaction. Evidence is presented to show that it is probably derived from the food. The chemical nature of the substance has not been ascertained. It forms a low proportion of the unsaponifiable fraction, is not cholesterol and probably not a member of the lipochrome pigments. It is thermostable in the absence of air or oxygen, but is rapidly destroyed by oxidation. The few properties of the substance which are known, as well as the available data regarding its distribution in natural products, show certain resemblances to the unidentified dietary unit known as vitamin A. The colour test cannot be regarded as specific for liver fats although they usually give the most intense reactions. The body fat, and fat from other organs of animals, especially if they have been fed on liver oils, may give the reaction.—H. C. R.

Perilla oil. K. H. Bauer. Farben-Zeit., 1922, **27**, 2756—2757.

The fatty acids of a sample of perilla oil were investigated. The oil had the following characters: Sp. gr., 0·9280 at 20° C.; $n_D^{20}=1·4830$; saponif. value, 187·4; iodine value (Hanus), 204·3; hexabromide value, 50·8. The mixed fatty acids separated by the lead salt-ether method gave 12% of saturated acids and 88% of unsaturated acids. The saturated portion consisted mainly of palmitic acid. The unsaturated acids were oxidised by Hazura's method and gave a hexahydroxystearic acid (m.p. 165° C.). A tetrahydroxystearic acid of m.p. 135°—140° C. was also found. The fatty acids of perilla oil would therefore seem to consist of a mixture of palmitic acid, a linolic acid, and several geometrically isomeric linolenic acids.—H. C. R.

Naphthalenesulphonic acids as agents for hydrolysing fats. E. Trepka. Przemysl Chem., 1922, **6**, 49—56. Chem. Zentr., 1922, **93**, IV., 265—266.

The α- and β-naphthalenesulphonic acids and 1.5-, 2.7-, 1.6-, and 2.6-naphthalenedisulphonic acids were tried as fat-hydrolysing agents. The position and number of sulphonic groups have no influence on the course of the reaction and the presence of these naphthalenesulphonic acids does not accelerate the hydrolysis of fats unless other compounds are present, which form complexes with the sulphonic acids. For instance the presence of Turkey-red oil considerably increases their fat-hydrolysing properties.—H. C. R.

Clupanodonic acid. M. Tsujimoto. Chem. Umschau, 1922, **29**, 261—262.

The highly unsaturated acid, clupanodonic acid, to which the peculiar odour of fish oils is probably due has the formula $C_{22}H_{34}O_2$ and not $C_{18}H_{28}O_2$, although a small quantity of an acid having the latter formula occurs in Japanese sardine oil (*cf.* Schmidt-Nielsen, J., 1922, 300 A). Majima and Okada (J., 1914, 362) found that the acids obtained by the debromination of the ether-insoluble bromides from Japanese sardine oil gave mainly behenic acid on hydrogenation. Clupanodonic acid has been obtained almost pure by fractionating the methyl esters obtained from the highly unsaturated acids from Japanese sardine oil by the lithium-salt-acetone method. It has the following properties:—A pale yellow liquid not solidifying at −50° C., thick like vaseline at −78° C.; sp. gr. 0·9398 at 15°/4° C.; neutralisation value, 172·5; iodine value (Wijs) 390 (theoretically 384·3); $n_D^{15}=1·5040$. Clupanodonic acid is one of the most widely distributed compounds in nature, occurring in the oils of all fresh and salt water fish, reptiles, and amphibious animals.—H. C. R.

Paraffin hydrocarbons and fatty acids; Catalytic oxidation of saturated ——. A. H. Salway and P. N. Williams. Chem. Soc. Trans., 1922, **121**, 1343—1348.

The catalytic oxidation of hexadecane and stearic acid by means of oxygen in presence of 2% of manganese stearate at 120°—130° C. gives rise to a complex mixture of substances, including monocarboxylic acids of the fatty series, dicarboxylic acids of the malonic series, together with lactones, lactonic acids, formic acid, and carbon dioxide. The paraffin hydrocarbon is probably first converted into a fatty acid, which is then further attacked at several points in the carbon chain with the formation of hydroxy-acids and lactones and these, in turn, are further oxidised and degraded. In the oxidation of stearic acid the volatile products amounted to about 5% of the original acid, the acids soluble in water to 8%, and the insoluble portion, containing only very small quantities of true fatty acids of lower mol. wt., to 86%—G. F. M.

Oils and fats; Rate of saponification of —— *by aqueous alkali under various conditions.* M. H. Norris and J. W. McBain. Chem. Soc. Trans., 1922, **121**, 1362—1375.

When neutral oils are boiled with alkali, the rate of saponification follows no simple formula but is greatly influenced by stirring, emulsification, and by the manner and degree of the salting-out of the soap. The rate is at first exceedingly slow, then rapid, and in the final stage again very slow, presumably due to the highly viscous nature of the medium towards the end of the reaction. The reaction depends largely on the surface of the oil exposed, and vigorous stirring increases the initial rate nearly twenty times. When once the oil is emulsified and sufficient soap has been produced to stabilise the emulsion, the reaction proceeds quite as quickly without stirring. Increase of the concentration of the alkali, insufficient to cause salting-out, increases the rate of saponification. Salting-out greatly reduces the rate, but further addition of alkali increases the rate almost in the proportion of the amount added; hence a large increase in concentration of alkali gives the highest rate. It is possible to saponify an oil to the extent of 99·8% within a few hours.—J. B. F.

Soap; Effect of an electrolyte on solutions of pure ——. *Phase-rule equilibria in the system sodium laurate, sodium chloride, water.* J. W. McBain and A. J. Burnett. Chem. Soc. Trans., 1922, **121**, 1320—1333.

A soap solution, from the phase-rule standpoint, may be regarded as a single phase when considering its equilibria with other solutions or solids. Soap solutions, such as solutions of sodium laurate, to which salt has been added may be regarded as three-component systems, involving water, sodium laurate, and sodium chloride. Three liquid layers may exist in equilibrium under suitable conditions, viz., concentrated liquid known as "neat" or "fitted" soap; liquid of moderate concentration known as "nigre"; liquid containing very little soap, known as "lye." The concentrations in these three layers are:—Sodium laurate $1·0N_\omega$, 0·5—$1·0N_\omega$, and $0·01N_\omega$; sodium chloride 1—$2N_\omega$, 2·5—$3N_\omega$, and 2·5—$6N_\omega$ respectively. Salt added to solutions of sodium laurate reduces the solubility of the soap in a regular manner highly dependent on temperature and concentration. All soap systems can be brought into the form of one homogeneous liquid at sufficiently high temperatures if decomposition is prevented. If the concentration of the sodium chloride is above $2N_\omega$, on cooling, a temperature will be reached at which two liquid layers are formed, but if the concentration of the soap, and particularly of the salt, is high enough, the ultimate result is the formation of a curd floating on a lye containing only traces of sodium laurate. Portions of the equilibrium diagram have been worked out for the system sodium laurate, sodium chloride, water.—J. B. F.

Patents.

Synthetic waxes; Manufacture of ——. G. Schicht A.-G., and A. Grün. E.P. 183,186, 17.3.21.

Aliphatic hydrocarbons of high molecular weight are oxidised by means of an excess of oxygen or gases containing oxygen at a temperature of at least 150° C. The products of oxidation are divided into a solid and a semi-solid portion by pressing or by means of organic solvents. For example, a paraffin melting at 52° C. gave a synthetic wax having the following characters: acid value, 21; saponif. value, 75·6; iodine value, 4·7. The synthetic waxes closely resemble beeswax.—H. C. R.

Soaps; Process for making odourless —— from marine animal oils. F. Fischer. G.P. 353,571, 14.3.19.

The soaps are dissolved in water, treated with alkali, and gases containing oxygen are then passed through the solution under increased pressure. For instance, compressed air at 30 atm. is passed into the aqueous soap solution at 170° C. in an autoclave. The air is afterwards found to be poor in oxygen and rich in carbon dioxide. In a comparatively short time odourless soaps are obtained, having great lathering power.—H. C. R.

Fatty acids from hydrocarbons. G.P. 350,621. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Naphthalene-formaldehyde condensation products; Preparation of —— and their suitability for the varnish industry. P. Folchi. Chem.-Zeit., 1922, **46**, 714—715.

Condensation products of naphthalene with formaldehyde, suitable for use in the lacquer or varnish industry, are prepared as follows: 100 g. of naphthalene is added to 80 c.c. of 30% formaldehyde, 100 c.c. of sulphuric acid (66° B., sp. gr. 1·84) gradually added, and the mixture heated under a reflux condenser on a water bath at 80° C. for 1½—2 hrs. with agitation. The contents of the flask are poured into water at 80°—90° C. and the melted condensation product washed with water, dilute alkali, and water again. The mass is then dried at 80° C. for 4—5 hrs. For use as lacquer the material is melted with a small quantity of turpentine and mixed with refined tar. By strict attention to the above reaction conditions a yield of 100—110% of the naphthalene used may be obtained. The hardness of the product varies with the temperature of formation. If the condensation product is granular this can be rectified by melting with turpentine and then washing with water. If the acid is not completely removed the mass will not dry satisfactorily. An alternative method is to use 100 g. of naphthalene, 80 g. of 40% formaldehyde, and 120 g. of sulphuric acid, heating for 3 hrs. at 90°—95° C.; in this case the yield is 80—90%. It appears to be a rule that formaldehyde condensation of unsaturated aliphatic hydrocarbons produces substances resembling caoutchouc, that of aromatic hydrocarbons materials of the bakelite type.—C. I.

Patents.

Carbon black and method of producing same. A. S. Cooper. U.S.P. 1,423,193, 18.7.22. Appl., 19.1.22.

Brown bitumen-bearing sand is powdered, and the finely divided bitumen is removed by a blast of air and heated to obtain carbon black.—D. F. T.

Paint vehicle. Paint composition. Pigment composition for paints. Oil. W. N. Blakeman. U.S.P. (a) 1,423,389, (b) 1,423,390, (c) 1,423,391, and (d) 1,423,392, 18.7.22. Appl., (a) 16.4.21, (b, c, d) 5.10.21.

An oil mixture (d) is obtained by blending tung oil and coconut oil. By mixing this with an anhydrous pigment a paste (c) is formed, which, by the further addition of a fatty oil and a mineral oil, yields a paint composition (b). A paint vehicle (a) is made by adding a mineral oil to the mixture of coconut oil and tung oil.—D. F. T.

Coating or sealing composition. M. J. Strauss. U.S.P. 1,423,821, 25.7.22. Appl., 31.1.21.

The precipitate obtained on adding sulphuric acid to a solution of shellac in aqueous sodium hydroxide is dissolved in alcohol. This solution when mixed with inorganic fibrous material yields permanently flexible coatings.—D. F. T.

Resinous masses; Process for the production of ——. Wenjacit Ges.m.b.H. G.P. 351,104, 17.8.15.

A small amount of benzoic, salicylic, or other easily fusible acid is stirred into a mixture of phenols, soaps, and aldehydes that has been heated until it has become a viscous mass, whereby polymerisation is arrested at the gummy stage. The mass is cast into moulds and then subjected to a known hardening process. For example, 2—3% of salicylic acid is added to the gummy mass obtained by heating 100 pts. of crude carbolic acid, 50 pts. of soft soap, and 100 pts. of formalin, and the product is cast into moulds. The resulting mass remains soft for more than six months, and may be used as a substitute for vulcanite.—A. R. P.

Artificial resin; Preparation of a white insoluble ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 351,349, 20.10.20.

A mixture of 1 mol. of a ketone and 6 mols. of formaldehyde in aqueous solution, or the equivalent amount of one of its polymers, *e.g.*, paraformaldehyde, or of one of its condensation products, *e.g.*, hexamethylenetetramine, is condensed in the presence of alkalis. Acetone and formaldehyde in this way yield a white powder, $C_8H_{12}O_4$, which is tasteless, odourless, infusible, insoluble in organic solvents, and unattacked by acids and alkalis. It is also difficultly combustible, and is a good electrical insulator.—A. R. P.

Resins, pitch, and the like; Process of hardening ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 352,521, 4.5.20.

Soft resins or pitches are heated, in the presence of mineral or organic acids, with furfural or its homologues, or with materials which form these compounds, under a reflux condenser or under pressure, and the resulting product is washed, dried, and melted, or recovered by extraction processes. The melting point of the hardened resin may be raised by melting it in a vacuum or by blowing air through it at 180°—350° C.—A. R. P.

Resins and resinous substances; Production of —— from cellulosic materials. Zellstoff-fabr. Waldhof, and V. Hottenroth. G.P. 353,380, 25.12.19.

Material containing cellulose, in addition to resins and the like, is treated with moderately concentrated sulphuric or hydrochloric acid, or mixtures of the same, and the solution is subsequently diluted with water and boiled, the cellulose being converted thereby into soluble dextrins and sugars. After filtration the residue, which contains resinous constituents together with lignin, is washed, dried, and extracted with resin solvents at normal or moderately high temperatures. The final residue may be distilled to obtain decolorising charcoal, methyl alcohol, and other products.—L. A. C.

Pigments; Process of making ——. L. R. Baker. U.S.P. 1,425,436—7, 8.8.22. Appl., 16.7.19 and 13.8.20.

See E.P. 161,280 of 1920; J., 1921, 399 a.

Coatings on galvanised or tinned metal. G.P. 351,981. *See* X.

Linseed oil substitute. G.P. 352,008. *See* XX.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Smoked sheet [rubber]; Effect of mould on quality of ——. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 330—331.

Although the grey-green, moss-like type of mould which develops normally in daylight has a retarding effect on the rate of vulcanisation, the black and yellow pin-head type which develops in the dark has an accelerating effect. With a slight surface mould the effect is inappreciable.—D. F. T.

[Rubber;] Additional tests with sodium silicofluoride [as a mould preventive for ——]. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 331—333.

The addition of sodium silicofluoride (*cf.* J., 1922, 510 A) to latex for the prevention of mould in the finished rubber, causes a reduction of 10—15% in the rate of vulcanisation of a simple mixture with sulphur (90:10); the physical properties of the vulcanised rubber are unaffected. The effectiveness of sodium silicofluoride, however, is limited, and rubber which was packed wet arrived in a mouldy condition, whatever the proportion of sodium silicofluoride used.—D. F. T.

Patents.

Rubber-containing latex; Process for treating ——. E. Hopkinson. E.P. 157,978, 11.1.21. Conv., 16.1.20.

In order to prevent premature coagulation the rubber latex is treated with 0·1% of ammonia, or if vulcanising agents or compounding ingredients are also added, with 0·1% of saponin, glycerin, or glue. The latex is then atomised by being delivered in a uniform stream against an air jet, the spray meeting a second stream of air heated to 200° F. (93° C.); the evaporation reduces this temperature almost immediately to about 130° F. (54° C.). The air carrying particles of rubber in suspension is led along a tortuous path, whereupon the rubber is deposited as a porous mass with as little as 0·6% of moisture; it can be compacted by hydraulic pressure. On account of the retention of the whole of the serum solids the yield of rubber is increased by approximately 10% (calculated on the rubber). The composition is roughly as follows, the bracketed figures giving the corresponding values for rubber prepared in the ordinary manner: Acetone extract, 5·2% (3·0%); ash, 1·5% (0·4%); water extract, 7·2% (0·3%); protein, 4·2% (2·0%); acidity expressed as acetic acid, 0·10% (0·02%). The new type of rubber on vulcanisation shows an increase of about 20% over the usual values for tensile strength and resistance to abrasion; the advantage can be still further increased by introducing the sulphur and other compounding ingredients into the latex before evaporation, thereby obviating the mechanical kneading involved in the ordinary mixing operation.—D. F. T.

Indiarubber; Improvement and regeneration of ——. E. Hug. E.P. 177,495, 20.2.22. Conv., 21.3.21.

Rubber articles, such as motor covers and inner tubes, are improved by successive immersion for half-hour periods, with 24-hour intervals, in an infusion of Roman camomile in castor oil at increasing temperatures, viz., 50°, 70°, and 80° C.
—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin; Dissolution of ——. F. Fairbrother and E. Swan. Chem. Soc. Trans., 1922, 121, 1237—1244.

Gelatin exists in solution in the liquid surrounding the gel, when the jelly is in equilibrium with water, dilute acid, or alkali. The solubility of gelatin in distilled water at 15°—17° C. is 0·05 g. in 100 c.c. A similarity exists between the solubility curves and the curves for the swelling and osmotic pressure of gelatin. The experiments indicate a minimum solubility of 0·01 g. and 0·03 g. per 100 c.c. for a concentration of 1 millimol. per litre of hydrochloric and sulphuric acid respectively, *i.e.*, less than for pure water. In general, however, gelatin dissolves to a greater extent in dilute acids or alkali than in water, whilst neutral salts decrease the solubility. The gelatin was estimated by precipitation with tannic acid. The acid and alkali solutions were first neutralised with potassium hydroxide or hydrochloric acid respectively. When electrolytes were absent, 1 c.c. of $N/20$ potassium chloride was added to 20 c.c. of the solution, since it was found that in the presence of salts the precipitate was coagulated, less gelatinous, and was more easily filtered. It was found that the ratio of gelatin to tannin was not constant, but varied with the concentration.—J. B. F.

Gelatin solutions; Gel-strength and viscosity of ——. E. T. Oakes and C. E. Davis. J. Ind. Eng. Chem., 1922, 14, 706—710.

Gel-strength is measured by a "plunger" method. A plunger is attached to the under-side of a balance-scale pan, on which is placed a beaker. The whole is counterpoised and water added to the beaker until the plunger is forced into a gel, placed below, to an arbitrary depth indicated by the deflection needle of the balance. The effect of the p_H value on gel-strength was determined, and also the relationship of gel-strength to viscosity. The molecular weight of gelatin was determined by acid titration over a definite p_H range. The figure varied very considerably between 1000 and 2000. The form of the gel-strength-p_H curve was the same for different concentrations. The maximum gel-strength coincided in p_H value with the maximum increase in viscosity for ageing solutions. Additional data were obtained in favour of the gelatin-acid combination theory.—A. G. P.

Patents.

Tanning skins; Process for ——. P. Ringbauer. G.P. 344,325, 16.11.20. Addn. to 321,343 (J., 1920, 666 A).

The pressure of the air in the tanning vessel before the introduction of the tanning liquid is not reduced to so great a degree as specified in the main patent, nor for as long a period of time. During the tanning process, on the other hand, the pressure is further reduced and for a longer period. The skins are by this means more thoroughly and rapidly tanned and after the subsequent stretching on frames the permanent extension of the fibres of the skin is more regular than that obtained according to the main patent.—H. C. R.

Skins and hides; Process for bating ——. C. H. Boehringer Sohn. G.P. 351,015, 13.4.17.

Pure or crude saponified bile acids or their salts, or mixtures of them, alone or in combination with other bating materials not containing bacteria or enzymes, are used as bating materials. Saponified bile acids, such as cholic, choleic, or desoxycholic acids, possess the advantages as bating agents that they contain neither undesirable impurities such as calcium salts of fatty acids and proteolytic enzymes, nor useless filling materials, such as dissolved or emulsified fats, fatty acids, or cholesterol. They are without odour, and can be accurately analysed. Saponified desoxycholic acid also has the property of forming with fats, fatty acids, and cholesterol crystalline compounds, alkali salts of which are easily soluble in water. The natural tauro- and gluco-desoxycholic acids lack these properties. The presence of bacteria and enzymes is not necessary in the bating process. The presence of other bating agents suitable for removing lime, such as sodium lactate, is, however, sometimes desirable.—H. C. R.

Skins; Process for tanning ——. Gerb- und Farbstoffwerke H. Renner und Co. A.-G. G.P. 353,076, 23.8.16.

Chloranil is mixed with such quantities of organic or inorganic dispersing media, *e.g.*, phenols, alkali or alkaline-earth hydroxides, as to produce a colloidal solution in which the skins are steeped. The chloranil may be produced from trichlorophenol by treating it with oxidising agents, such as bichromates, and the impure chloranil used without further treatment. Any excess of phenols is to be avoided, as otherwise the colloidal solution is converted into a true solution having no tanning action. If hydroxides of alkali or alkaline-earth metals are used as dispersing medium, part of the chloranil is converted into alkali or alkaline-earth salts of chloranilic acid. These salts are soluble and have a peptising action on the unaltered chloranil. To make up such a tanning solution finely divided chloranil is shaken with 200 times its weight of water in the tanning vessel and a quantity of phenol, amounting to one-tenth of the chloranil used, is added. The concentration of the liquor can be varied. The tanning action of chloranil solutions is considerably greater than that of solutions of quinone and its substitution products. If the chloranil is produced by the oxidation of trichlorophenol with bichromate, the tanning action of the chromium compounds is available also. Colloïdal chloranil solutions can also be used in conjunction with all known natural or artificial tanning agents.—H. C. R.

Chrome leather; Process for neutralising ——. O. Röhm. G.P. 352,285, 18.11.16.

Sodium carbonate or other alkali or alkaline-earth carbonate is used in conjunction with formaldehyde or alkali or alkaline-earth salts of the lower fatty acids or oxyacids. The formaldehyde prevents the basic chromium salt becoming too strongly attached to the grain of the leather, with resulting ropiness and brittleness of the latter. Chromium salts of the lower fatty acids are produced and these are more strongly basic and consequently better for tanning than chromium salts of mineral acids. Wet chrome-leather is neutralised, for example, by treating it with aqueous sodium carbonate and formaldehyde, or with water, calcium carbonate, and sodium formate in the fulling-mill. Acetates or lactates of alkali or alkaline-earth metals can be used instead of the formates.—H. C. R.

Fish refuse and the like; Production of a plastic mass from ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 352,534, 30.6.20.

Fish meal, fish guano, etc. is treated with acids, separated from large foreign particles and is re-precipitated by the addition of a large quantity of water or of a calculated quantity of alkali, the precipitate being rendered insoluble either by heating to 100°—180° C., or by warming with an aldehyde (formaldehyde or furfural) or with tanning materials, and then mixed with fibrous or pulverulent materials, such as wood meal, cellulose, asbestos, and the like. During the process for rendering the precipitate insoluble, it may be mixed with a small quantity of a ketone, or phenol, or tar oils, pitch, wax, resin, rubber, colouring matter, etc. Unless powdered material is added the material has no appreciable resistance to breakage.—A. G.

Material resembling horn; Production of ——. Ges. f. Technik m.b.H. G.P. 352,594, 3.9.15.

Phenols and aldehydes are heated together in the presence of sodium benzoate or salicylate until a product is formed having the consistency of castor oil, and the product is hardened by heating in closed moulds to 120°—140° C.—L. A. C.

Leather; Process for the impregnation and currying of ——. H. Burger. E.P. 157,929, 10.1.21. Conv., 14.5.14.

See G.P. 303,204 of 1914; J., 1921, 442 A.

Oxalic acid from leached tan-bark. G.P. 352,576. *See* XX.

XVI.—SOILS; FERTILISERS.

Ammonium bicarbonate; Manufacture and employment of —— *as a fertiliser.* W. Gluud. Chem.-Zeit., 1922, 46, 693—697, 715—717.

The present economic situation in Germany and in particular the dearness and scarcity of sulphuric acid have directed attention to the possibility of replacing ammonium sulphate for fertiliser purposes by ammonium bicarbonate. A series of field trials carried out in the summer of 1921 with equivalent quantities of the two compounds applied to rye, oats, potatoes, roots, and meadow, gave the general result that the bicarbonate approached the sulphate in value and in some cases equalled it. No serious loss from volatilisation seems to have occurred, at any rate when the manure was raked or harrowed in. The bicarbonate does not render the soil acid, and in view of recent work on the fertilising value of carbon dioxide its content of the latter should be beneficial. The salt can be prepared in a condition suitable for sowing and does not cake. The main difficulty has always been its volatility, but while some loss always occurs it is believed to be mainly carbon dioxide, a sesquicarbonate being first formed. Packed in second-hand casks the salt lost 2·75% of its weight in 30 days. In paper bags treated externally with soluble coumarone-resin the loss in the same period was 0·5%. The material may be advantageously compounded with superphosphate. Gasworks and coke ovens working the indirect or semi-direct ammonia recovery process can be easily adapted to manufacture bicarbonate. 20% ammonia liquor is run into a water-jacketed horizontal cylinder fitted with an agitator, and a current of carbon dioxide derived by distillation from the dilute crude liquor from the washer is blown through for 10—12 hours. Traces of ammonia carried forward are absorbed in acid, and at the end of that time the contents are run off and the separated salt is centrifuged. This process is not readily applied to those coke-ovens working the Otto direct recovery method, and such will probably continue to make sulphate. Cost figures show a saving by the production of bicarbonate, after allowing for a 5% loss in storage, compared with the process at present in use. While there is not such an inducement to the synthetic nitrogen industry to manufacture bicarbonate on account of the existence of plants deriving sulphuric acid from gypsum and the great advantages of urea, yet even in such cases the bicarbonate will be the cheapest form of nitrogen compound to produce.—C. I.

Nitrogen losses from dung and urine during storage; Studies in methods to prevent ——. N. V. Joshi. Agric. J. India, 1922, **17**, 367—374.

Fresh samples of dung and of urine were collected and stored in jars, some of which were sealed and others left open to the air. The nitrogen content of the samples was determined at intervals. The nitrogen losses from dung, under both aerobic and anaerobic conditions were small; whilst urine lost considerable amounts of nitrogen when stored aerobically. By storage under anaerobic conditions, *e.g.*, by covering with paraffin or other oils, nitrogen losses were prevented. The addition of sulphuric acid, superphosphate and formalin prevents loss of nitrogen from stored urine, but the cost is excessive. Very great losses were observed when urine was absorbed in soil beds or in straw. It is advisable to store animal dung and urine in separate pits.—A. G. P.

Azotobacter chröococcum; Influence of humus on the sensitiveness of —— towards boron. J. Voicu. Comptes rend., 1922, **175**, 317—319.

Cultures of the organisms were treated with boric acid in varying quantity, and measurements were made of the rate of nitrogen fixation in the presence of humus. In the absence of humus the action of boric acid on the rate of nitrogen fixation is insignificant, but the addition of humus increases both the amount of nitrogen fixed and the toxicity of the boric acid.—A. G. P.

Elimination of borates from American potash. Ross and Hazen. *See* VII.

Iron and aluminium in phosphates. Nydegger and Schaus. *See* VII.

Patents.

Plants; Prevention of damage to ——, especially by nematodes. H. Stoltzenberg. G.P. 351,300, 21.7.20. Addn. to 316,503 (J., 1920, 290 A).

A product suitable for preventing the growth of nematodes is obtained by subjecting saturation scum from sugar refining to destructive distillation, and mixing the distillate, which contains hydrocyanic acid, with the retort residue. The percentage of hydrocyanic acid in the distillate can be increased by adding molasses or vinasses to the saturation scum prior to distillation.—A. B. S.

Dibasic calcium phosphate; Means for reducing the amount of acid required in the production of ——. Bayerische A.-G. für chem. und landwirtschaftl. chem. Fabrikate, and H. Hackl. G.P. 352,782, 12.2.20.

The amount of acid usually required is reduced by adding finely ground bone-meal and water to the monobasic calcium phosphate produced in the customary manner.—A. B. S.

Fertiliser; Production of a ——. C. Kroseberg. G.P. 353,371, 8.6.21.

A solution of magnesium chloride, *e.g.*, waste liquor from the potash industry, is heated with an excess of aqueous ammonia in a closed vessel under pressure. The product is filtered, and the filtrate, after addition, if necessary of the requisite quantity of sulphuric acid or ammonium sulphate to react with any undecomposed magnesium chloride still present, is evaporated to dryness.—A. B. S.

XVII.—SUGARS; STARCHES; GUMS.

Moisture absorptive power of different sugars and carbohydrates, under varying conditions of atmospheric humidity. C. A. Browne. J. Ind. Eng. Chem., 1922, **14**, 712—714.

Various carbohydrates were exposed to a moist atmosphere at various temperatures and degrees of saturation and the rate of absorption of water measured. At 20° C. and 60% humidity, starch was the most absorptive, followed by cellulose and agar. Lævulose was relatively low in the series, and dextrose, mannitol, and sucrose were the least absorptive. In a saturated atmosphere lævulose showed the greatest absorptive power. When allowed to stand under ordinary atmospheric conditions, after exposure to a saturated atmosphere, all substances lost moisture except lactose and raffinose, which continued to gain for many months. Where water was absorbed in excess of the amount required to form a monohydrate the excess was lost on exposure to a drier atmosphere. No definite relationship between percentage of humidity and absorptive power was found.—A. G. P.

2.3.6-Trimethylglucose. J. C. Irvine and E. L. Hirst. Chem. Soc. Trans., 1922, **121**, 1213—1223.

The isolation and physical properties of 2.3.6-trimethylglucose, one of the hydrolysis products obtained from trimethylcellulose, and indirectly from lactose and cellobiose, has been further studied. As no crystalline derivatives of the sugar could be obtained, its identification depends primarily on its isolation in a pure crystalline condition from the mixed hydrolysis products. Of all the methods examined the most satisfactory consisted in separation of most of the sparingly soluble alkylated galactose by fractional crystallisation of the anilides, regeneration of the sugar from the more soluble anilides, conversion into the corresponding methylglucosides, and fractionation of these in a high vacuum. The middle fraction consists mainly of trimethyl-methylglucoside, and after hydrolysis and crystallisation from ether the pure substance is obtained in well-formed needles, m.p. 122°—123° C. A dimorphic form crystallising in short prisms, m.p. 92°—93° C., was also obtained. This did not consist of the β-form of the sugar. Other constants observed were $n_D = 1{\cdot}4743$ (of the syrup), $[\alpha]_D$ in methyl alcohol $= +117{\cdot}7° \rightarrow 88{\cdot}6°$ (no catalyst), $[\alpha]_D$ in water $= +90{\cdot}2° \rightarrow 70{\cdot}5°$ (no catalyst). The final optical value in aqueous solution agrees with that obtained on hydrolysis of the methylglucoside, which latter is a colourless mobile syrup, b.p. 150° C. at 0·07 mm. The constitution of 2.3.6-trimethylglucose was further confirmed by its oxidation with nitric acid to a dimethylsaccharic acid.—G. F. M.

Dextrin; Specific heat and heat of wetting of ——. Sprockhoff. Z. Spiritusind., 1922, **45**, 217.

The specific heat was determined calorimetrically by mixing with petroleum. The average figure was 0·355 for anhydrous yellow dextrin and 0·363 for the white variety. The "heat of wetting" was obtained by moistening the dextrin directly with water or by adding water to a petroleum suspension of dextrin. An average figure of 16·5 cals. per g. was found. Experiments with starch showed that the greatest heat evolution occurred on the addition of the first 1% of water.—A. G. P.

Patents.

Sugar; Process for refining —— without producing molasses. A. A. Holland. G.P. 351,376, 27.9.18. Addn. to 348,064 (J., 1922, 386 A).

The sugar is dissolved in water, the solution filtered, and the filtrate dried by means of hot air. A product of high quality is obtained and the whole of the sugar is recovered. The clear solution may be sprayed from nozzles or atomised by centrifugal methods, while being subjected to the action of the hot air.—H. C. R.

Starch; Process for making a —— which forms a paste with cold water. F. Supf. G.P. 351,870, 24.10.19.

The starch is treated with concentrated alkali hydroxide below 0° C., so that no paste is formed, and the quantity of alkali hydroxide is so regulated that on allowing the temperature to rise the reaction which takes place causes the disruption of the starch granules without gelatinisation. It is not necessary to suspend the starch in water-repelling liquids before treating it with the alkali hydroxide. The product can be used with advantage in the textile industry for finishing, as a thickening agent in calico printing, as a size, or for wall-papering.—H. C. R.

Preventing growth of nematodes. G.P. 351,300, *See* XVI.

Sugar from wood. E.P. 164,329. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Saccharomyces Odessa, nov. spec. H. Schnegg and F. Oehlkers. Z. ges. Brauw., 1922, 45, 92—96, 106—107, 111—113.

This yeast, isolated from the beer of an Odessa brewery, consists normally of almost round or slightly oviform cells and on 8—10% beer wort forms a slight film and a ring growth which gradually extends to the rim of the culture vessel. Both the film and the ring contain many long, sausage-shaped cells and occasional giant cells. The organism readily forms from 1 to 3 spores per cell, these being obtained better on filter paper than on plaster blocks and in greater abundance if the yeast is previously grown in a strong rather than in a weak wort. The giant colonies formed on wort-gelatin closely resemble those obtained with Frohberg yeast. The degree of fermentation obtained with 7·9% wort is about 62%, and the yeast ferments sucrose, dextrose, lævulose, maltose and mannose readily, galactose and raffinose slightly, and lactose, mannitol, dextrin, glycerol, amygdalin and inulin not at all. The organism is distinctly thermophilic and reproduces most rapidly at 32° C. The spores exhibit extremely high refractivity, and under suitable conditions some of the mother cells containing spores are capable of germination without the spores themselves undergoing alteration.—T. H. P.

Fermentation accelerators. Inouye. Woch. Brau., 1922, 39, 191—193.

The author has repeated with Japanese bottom fermentation brewery yeast, both fresh and dried, and with the pressed juice prepared therefrom, the experiments of Neuberg and his collaborators on the effect of certain aldehydes, ketones, diketones, disulphides, etc. on the velocity of the fermentation. The stimulating action observed is most marked with the pressed juice and least marked with the dried yeast. Contrary to Neuberg's result, vanillin is found to have a distinct, although slight, accelerating action on fermentation by yeast juice. With juglone, fenchone, and irone the effect is more pronounced. Neutral organic salts exert no action, although Von Euler and Casel observed activation by such compounds. Shikimic, abietic and cholic acids cause slight activation. The fact that acetaldehyde effects permanent acceleration of fermentation supports Neuberg's scheme for the mechanism of fermentation. Xylose and uric acid also accelerate fermentation.—T. H. P.

Yeast; Development and nutrition of ——. A. Tait and L. Fletcher. J. Inst. Brew., 1922, 28, 597—618.

Fermentation experiments have been carried out at 65° F. and under varying conditions as regards amounts of seed yeast, nitrogenous nutrients, etc. Confirmation is obtained of A. J. Brown's observation that the quantity of new yeast formed is practically independent of the proportion of seed yeast used. The shape of the vessel employed exercises a marked influence in laboratory fermentations. As regards nitrogenous nutrition, the results obtained by Stern (J., 1899, 933) with artificial nutrients are so much at variance with everyday practical observations that they must be regarded as abnormal and as controlled by a dominant factor other than those specified. Similar abnormality has been encountered by the authors in experiments in which the nitrogenous pabulum of the yeast consisted of asparagine, and it is found that growing yeast, in its search for nitrogenous food, breaks down asparagine with final production of malic acid, which acts as a poison and inhibits reproduction when its concentration attains a certain value. When, however, asparagine is used in conjunction with other amphoteric substances, it is possible for yeast to assimilate a greater proportion of nitrogen. The favourable influence exerted on the assimilation of nitrogen and the development of yeast by addition of calcium carbonate to an asparagine medium is only slight and less than was expected; the cause of this lies partly in a mechanical clogging of the yeast by the particles of carbonate with consequent diminution of the diffusion surface. Certain other substances, such as barium sulphate and kaolin, exhibit a similar effect. The fact that asparagine is not a suitable food for *Saccharomyces cerevisiæ* furnishes an explanation of the formation of thin, unstable beer of poor flavour when the use of slack or forced malt gives rise to an excessive proportion of amino-acids in the wort. Yeasts grown in presence of widely different proportions of nitrogenous compounds vary considerably in nitrogen content and the fermentative power varies approximately linearly with the nitrogen content. If, then, two portions of the same wort are pitched with equal quantities of two yeasts of the same species, one of high and the other of low fermentative power, the resulting crops exhibit to a considerable degree the parental fermentative characteristics; this apparent heredity is, however, observable only when the number of generations of yeast produced is very small.—T. H. P.

Enzymo-chemical observations. I. Action of foreign enzymes on yeast invertase. II. Rôle of phosphates in the degradation of carbohydrates. H. von Euler and K. Myrbäck. Arkiv Kemi, Min. Geol., 1921, 8, No. 17, 1—15. Chem. Zentr., 1922, 93, III., 524.

Treatment of invertase for some days with a culture of either *Bacillus macerans* or *Aspergillus oryzæ* or with the digestion juice of *Helix Pomatia* results in the removal of part of the impurities of high molecular weight but leaves the invertase unweakened. In the esterification of dextrose and maltose under similar conditions, approximately double as much phosphate remains non-esterified in the latter as in the former case. As regards the course of fermentation in presence of toluene, sucrose and maltose exhibit the same behaviour, the toluene retarding the liberation of carbon dioxide only at the commencement of the reaction. In germinating and ripening seeds, extensive isomerisation of the carbohydrates takes place, dextrose being transformed into lævo-rotatory sugar and partially re-formed; in this process, which is intimately connected with the combination of phosphate, a part is probably played by a sugar-isomerising enzyme.—T. H. P.

Starch; Estimation of unsaccharified —— in brewers' grains. H. Weiss. Z. ges. Brauw., 1922, **45**, 122—124.

The following sedimetric method for the estimation of unsaccharified starch in brewers' grains yields accurate results in far less time than saccharification by means of diastase or malt extract and subsequent determination of the quantity of extract thus removed from the grains; 10 g. of the wet grains is well triturated with 10 c.c. of water in a porcelain casserole and then heated carefully to boiling during 10 minutes with 80 c.c. of calcium chloride solution (1 part of the anhydrous chloride and 1 part of water); if alkaline to phenolphthalein, the calcium chloride solution must be neutralised by addition of acetic acid before use. The contents of the casserole are transferred quantitatively by means of hot water to a 100 c.c. flask, cooled, made up to volume, mixed, and filtered through a dry pleated filter paper. A starch solution is also prepared by heating 1 g. of barley (or wheat) starch, dried at 100° C., with 10 c.c. of water and 50 c.c. of the calcium chloride solution in a 100 c.c. flask and afterwards treating in the same way as the wet grains. Of the two solutions thus obtained 10 c.c. is mixed with 1 c.c. of $N/2$ iodine solution in two sedimentation tubes having the narrowed bottom portion graduated. After a short time the starch iodide should separate out and the supernatant liquid should be, not colourless or blue, but distinctly yellow. The tubes are then centrifuged for 10 minutes at not less than 1200—1400 revs. per minute, and the percentage of unsaccharified starch in the grains calculated from the volumes occupied by the starch iodide in the two cases. Where no suitable centrifuge is available, 10 c.c. of the starch solution from the grains is diluted in a 200 c.c. cylinder with 100 c.c. of water and the liquid treated with very dilute iodine solution until the maximum blue coloration is attained. The solution of pure starch is treated similarly and the coloration of the one or the other liquid adjusted by dilution to equality with that of the other.—T. H. P.

Patents.

Sugar; Process for the manufacture of [fermentable] —— from wood and other cellulose-containing substances. A. Classen. E.P. 164,329, 1.6.21. Conv., 4.6.20. Addn. to 142,480 (*cf.* J., 1921, 405 a).

The wood is converted into sugar by means of a mixture of hydrochloric acid and sulphuric acid (the former acid preferably predominating and the mixture being sufficient for the conversion), with the addition of a catalyst consisting of a small amount of an acid or an acid salt or a mixture of both. Protective substances, such as metals or metallic oxides, may also be added.—J. R.

Yeast; Process of drying ——. E. Klein. E.P. 175,622, 10.2.22. Conv., 15.2.21.

Whilst moist yeast is being reduced by mechanical means to the greatest possible fineness, warm air is circulated through it. The dry yeast powder is carried away by the warm air current and deposited in a separate vessel.—J. R.

Glycerin; Process of recovering —— [from fermentation products]. J. A. Steffens, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,423,042, 18.7.22. Appl., 19.11.19.

Glycerin is recovered from materials subjected to alcoholic fermentation by precipitating the organic materials with an acid, distilling off the water, leaching with a liquid, and recovering the glycerin from the liquid by distillation.—T. A. S.

Beer containing lecithin; Process for brewing ——. W. Schmitz. G.P. 353,734, 22.6.13.

Lecithin is rendered soluble in water and largely freed from its fatty acid components by treatment with alcoholic potassium hydroxide, and is added to the mash together with the usual albuminous residue. The addition of the lecithin during the brewing causes the formation of lecithin-albumin and lecithin-peptone, which remain in solution in the beer.—H. C. R.

XIXa.—FOODS.

Milk analysis by semi-microchemical methods. H. Lührig. Milchw. Zentr., 1922, **51**, 157—159, 169—172.

Slight modifications of existing methods of milk analysis are given, whereby only 1 g. or less of milk is required for each determination. The following determinations are dealt with:—Sp. gr., fat, dry matter, sp. gr. of milk serum, ash of milk serum, qualitative test for nitric acid, acid value, total nitrogen, lactose.—H. C. R.

Condensed milk; Analytical investigations on the ageing of ——. G. Viale and A. Rabbeno. Biochem. Terap. Sperim., 1921, **8**, 325—352. Chem. Zentr., 1922, **93**, IV., 263.

Condensed milk was examined after keeping for periods of from ½ to 8 years. The sp. gr., dry matter, and conductivity showed no constant changes with time. The viscosity increased with the age of the sample. The total acidity in most cases showed an increase in the older samples, but was subject to considerable variations. No oxidases or reductases were found in the condensed milk. The time of coagulation with rennet was considerably greater with condensed than with fresh milk. The total nitrogen corresponded to an average albumin content of 8·65%, which indicates a concentration of 1:3. The mean content of casein was 8·35% and this was not altered by time. The very low content of non-albuminous nitrogen in fresh milk is more than doubled by condensing and still further increased by keeping the condensed milk. The amino-acids are decreased and only amount to 0·0068—0·021%. Polypeptides, absent in fresh milk, show a marked increase on keeping condensed milk. In old samples tyrosine can be detected. The increased acidity causes a slow hydrolysis of the proteins. The samples analysed contained 6—13·7% of lactose and 32—40% of sucrose. The older samples showed a decrease of lactose to half the original figure and a decrease in sucrose to about 15%. A partial inversion of disaccharides took place. This can be ascribed to the increase in acidity. The fat content in fresh samples was 8·6%, and fell after keeping for several years to 3·43%. The free fatty acids increased slightly, while the volatile fatty acids slightly decreased. The relation between saturated and unsaturated fatty acids showed no constant change, nor did the quantity of cholesterol present, which was about 0·024—0·12%. The milk loses sweetness and becomes brown after storage for several years owing to the oxidation of amino-acids (tyrosine) or to decomposition of the sugars.—H. C. R.

Nitral; Biological action of —— and its bearing on the hygiene of nutrition. H. Bart. Arch. Hyg., 1922, **91**, 1—40. Chem. Zentr., 1922, **93**, IV., 259.

Nitral is purified moist nitrous oxide. Although this gas in the dry state possesses no bactericidal action, the moist gas at increased pressures kills all vegetative forms of bacteria, but not spores and conidia. Fresh milk treated with nitral at 30—35 atm. can be preserved so as to keep for at least a month without special cooling or precautions even at 18°—37° C. Living pathogenic germs other than *B. tuberculosus hom. and bov.*, suspended in milk, when treated with nitral at 48 atm. and 37° C., after 5 days treatment were weakened to such an extent that they no longer gave a reaction on a medium of lactose, litmus and nutritive agar. For tubercle bacilli a nitral concentration corresponding to a pressure of 50 atm. at 37° C. was necessary. After 8 days treatment guinea pigs could no longer be infected with the cultures. The original properties of the milk are fully retained after treatment with nitral. Meat can also be preserved in the same way as milk. Meats of the most varied kinds after treatment with nitral at 38 atm. pressure, all kept for at least a month at 18° C.—H. C. R.

Jams; Detection of apple juice in ——. C. F. Muttelet. Ann. Falsif., 1922, **15**, 196—200.

The acidity of red and black currants, raspberries and strawberries is due to the presence of citric acid, that of apples and pears to malic acid; cherries also contain malic acid. It is proposed to base the detection of apple juice in jams made with the first-mentioned fruits on the determination of the quantity of malic acid in the mixture. One hundred g. of the sample is warmed with 50 c.c. of water, cooled, treated with 150 c.c. of alcohol, then diluted with water to 300 c.c., and filtered after some hours; if the filtrate is highly coloured it must be decolorised with well-washed charcoal. The total acidity is titrated in a portion of the filtrate; another portion of 100 c.c. is mixed with 200 c.c. of 95% alcohol, neutralised by the addition of the required quantity of $N/1$ potassium hydroxide solution, and 30 c.c. of 5% barium bromide solution (in 85% alcohol) is added. After a few hours the precipitate of barium citrate and malate is collected on a filter and washed with 80% alcohol until free from soluble barium salts. It is then washed with water into a flask, the volume made up to 100 c.c., the mixture heated at 100° C. for 1 hr., cooled, filtered, and the filtrate treated with 50 c.c. of 95% alcohol; barium citrate is precipitated and is collected on a filter. The filtrate from this precipitate is evaporated to 50 c.c., cooled, and treated with 25 c.c. of alcohol; the last traces of barium citrate are thus precipitated and are collected. The filtrate is then evaporated to 25 c.c., cooled, and 50 c.c. of 95% alcohol is added; the precipitated barium malate is collected, washed with 66% alcohol, then dissolved in water and the barium precipitated and weighed as barium sulphate. Barium sulphate × 0·574 = malic acid. Apple and quince jellies examined by this method yielded 0·172—0·310% of malic acid, but the presence of this acid was not detected in currant and raspberry jams.—W. P. S.

Pectin; Study of the relation of —— and acidity in jelly making. L. Singh. J. Ind. Eng. Chem., 1922, **14**, 710—711.

The effect of acid concentration on the amount of sugar required to produce the "jellying" of fruit juice is considerable, an increase from 0·05 to 2·05% of acid reducing the sugar required by over 30%. If jelly is prepared below 65% sugar concentration the product and container must be pasteurised. Within certain limits the higher the amount of pectin in the juice the lower is the quantity of sugar needed to produce a jelly. If much more than 2% of pectin be used the excess separates and remains inactive on the surface. Waste lemon peels from citric acid factories were found to be extremely rich in pectin.—A. G. P.

Patent.

Iron and other magnetically permeable metals; Apparatus for separating —— from flour, grain, and the like. F. King. E.P. 183,940, 4.5.21.

XIXb.—WATER PURIFICATION; SANITATION.

Tubercle bacillus; Action of tribromoxylenol on ——. T. Duboc. Comptes rend., 1922, **175**, 326—328.

Tribromoxylenol, added to emulsions of tubercle bacilli, caused the separation of the organisms in a layer at the surface of the liquid, and their gradual disappearance, leaving the liquid perfectly clear. Bovine, avian, and human organisms were examined, and the time of final disappearance was found to vary with the strain, and previous treatment. (*Cf.* J.C.S., Sept.)—A. G. P.

Patents.

Deaerating of liquids [boiler-feed water]; Heating and ——. D. B. Morison. E.P. 183,534, 15.4.21.

In a method of deaerating liquids by heat treatment (*cf.* E.P. 173,524; J., 1922, 193 A), the deaeration effect is enhanced by re-circulating the warm deaerated liquid after mixing it with the inflowing liquid of lower temperature and higher aeration.—J. R.

Sewage water; Apparatus for the treatment of ——. V. Lamy. E.P. 167,504, 8.8.21. Conv., 7.8.20.

The sewage is fed to the bottom of a tank through a "trompe-blowing" device (water-jet pump), and, together with the entrained air, rises in a tube surrounding the fall tube of the pump, and overflows into a space enclosed by a cylindro-conical baffle concentric with the tubes. After flowing under the lower edge of the baffle, the liquid rises in the space between the baffle and the wall of the tank and is discharged. The tank is provided at the bottom with an outlet for settled sludge. In its passage through the apparatus the sewage is strongly aerated and agitated in the presence of the fine particles of sludge, whereby the major portion of the colloidal substances present is precipitated. The space between the tube and baffle is of such size that the time of circulation of the sewage corresponds to the time necessary for fermentation to be completed.—J. R.

Purification of [phenol-]contaminated liquors. The Koppers Co., Assees. of R. L. Brown. E.P. 161,976, 11.4.21. Conv., 30.4.20.

The waste liquor from ammonia stills, or other liquor containing phenol, is passed through a settling tank and a filter containing iron oxide. A suitable filtering medium is spent blast-furnace slag resulting from the treatment of mine water by the Heckman process. The still waste may be also treated for the removal of cyanogen compounds. It is then slowly passed through a filter composed of peat or other humus material mixed with coke so as to permit of free access of air and containing aerobic bacteria which oxidise the phenols and thiocyanates. In starting a filter the aerobic bacteria are supplied by means of activated sewage sludge or farmyard manure. About 85% of the filtrate is returned, so as to reduce the phenol concentration in the filter to 1—2 parts per 10,000.
—H. Hg.

Arsenical dust; Production of ——. J. D. Riedel A.-G. G.P. 301,686, 3.7.15, 302,406, 8.9.15, and 302,407 17.7.15.

A mixture of arsenic oxides with aluminium, or a mixture of aluminium with metallic oxides and substances containing arsenic, is ignited, and burns like thermite, with production of free arsenic, which is immediately oxidised, and forms a dense heavy fog, which rapidly settles. The mixture may be used for killing wild rabbits etc., its poisonous nature being increased by the addition of highly calcined alkali sulphide, as when this is present, and the mixture is ignited, arsenites are formed, which are much more poisonous than the oxide. The addition of ammonium chloride also increases the poisonous nature of the material, as arsenic chloride and hydride are then formed.—A. B. S.

Disinfectants; Manufacture of ——. Chem. Fabr. Griesheim-Elektron. G.P. 354,593, 14.12.20.

A tar oil phenol or mixture of phenols, pure or mixed with neutral tar oil, is mixed with carbon tetrachloride and soap in such proportions that a fluid or semi-solid product is obtained, from which on treatment with water neither the carbon tetrachloride nor the phenol or phenol and tar oil will separate. Glycerin or similar substances may also be added. The products, unlike lysol, are stable in presence of water containing lime.

Treatment of sewage sludge. E.P. 183,180. *See* IIa.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Aucubin and sucrose; Presence of —— in the seeds of Melampyrum arvense, Linn. M. Bridel and M. Braecke. J. Pharm. Chim., 1922, **26**, 129—134.

The seeds of *Melampyrum arvense* contain in addition to the glucoside, aucubin, which has previously been found in the leaves and stems of this plant, and which is hydrolysed by emulsin but not by invertase, a considerable quantity of a disaccharide, hydrolysable by invertase and giving polarisation figures closely corresponding to those of sucrose. Aucubin, isolated from the alcoholic extract, was obtained in colourless needles, m.p. 181° C., $\alpha_D = -174{\cdot}85°$. When hydrolysed by emulsin or sulphuric acid a black insoluble product is formed, which is characteristic of this glucoside, and also of rhinanthin, a glucoside occurring in *Rhinanthus Crista-Galli*, Linn., and it is possible that the two substances may be identical.—G. F. M.

Isoferulic acid; New syntheses of——. F. Mauthner. J. prakt. Chem., 1922, **104**, 132—136.

Isoferulic acid (3-hydroxy-4-methoxycinnamic acid) has been synthesised by reducing 4-methoxy-3-nitrocinnamic acid to 4-methoxy-3-aminocinnamic acid, m.p. 179°—180° C., and then replacing the amino group by hydroxyl. Another synthesis is from isovanillin, prepared by partial methylation of protocatechuic aldehyde, by condensation with malonic acid in acetic acid solution. Carbon dioxide is lost spontaneously, and isoferulic acid is formed. (*Cf.* J.C.S., Sept.)—W. O. K.

Mellitic acid, pyromellitic acid, and their production from carbon by oxidation. E. Philippi. Annalen, 1922, **428**, 286—287.

An introduction to the accompanying papers (*cf. infra*).—C. K. I.

Mellitic acid, pyromellitic acid, and their production from carbon by oxidation. I. Oxidation of carbon by nitric acid. E. Philippi and G. Rie. Annalen, 1922, **428**, 287—295.

The purification of the crude product of this reaction is a difficult matter, and the chief value of the process lies in the fact that pyromellitic acid can be obtained in 30% yield from the crude product by heating with sulphuric acid and bisulphate. —C. K. I.

Mellitic acid, pyromellitic acid, and their production from carbon by oxidation. II. Oxidation of carbon by sulphuric acid. E. Philippi and R. Thelen. Annalen, 1922, **428**, 296—300.

For the preparation of pyromellitic acid, finely powdered wood charcoal (100 g.), commercial sulphuric acid (1200 g., sp. gr. 1·76—1·80), and one globule of mercury, are heated during 3 hours to 250° C., during a further half-hour to 295° C., and then gradually to 315° C., at which temperature the mass is maintained until frothing ceases. The product is then distilled from a retort with the addition of 30—40 g. of potassium bisulphate, the pyromellitic anhydride being collected in water. The yield of pyromellitic acid is 6—7 g. (*Cf.* J.C.S., Sept.)—C. K. I.

Mellitic acid, pyromellitic acid, and their production from carbon by oxidation. III. Synthesis of pyromellitic acid from commercial xylene. E. Philippi, R. Seka, and N. Froeschl. Annalen, 1922, **428**, 300—306.

Commercial xylene is converted by means of acetyl chloride and aluminium chloride into a mixture of acetylxylenes, which are reduced to ethylxylenes. These are re-acetylated in the same manner, and the mixture of acetylethylxylenes reduced to diethylxylenes, which on oxidation by nitric acid give pyromellitic acid. (*Cf.* J.C.S., Sept.)—C. K. I.

[Fatty] acids of low molecular weight; Catalytic decomposition of ——. A. Mailhe. Bull. Soc. Chim., 1922, **33**, 681—687.

Acetic, isobutyric, butyric, isovaleric, and pelargonic acids were heated to about 600° C. in contact with copper-aluminium and the resulting products examined. Carbon monoxide, carbon dioxide, methane, and hydrogen were produced in different proportions in each case. With the exception of acetic acid, each substance also yielded some other paraffins and some olefines. With the acids of higher molecular weight, liquid products were also obtained; this was most marked in the case of pelargonic acid. It is shown that in each case the corresponding ketone (acetone, isobutyrone, butyrone, isovalerone, nonylone) is an intermediate product and by its decomposition forms certain of the end products.—H. J. E.

Trimethylene isomerism. Velocity of ring fission in gases. M. Trautz and K. Winkler. J. prakt. Chem., 1922, **104**, 53—79.

Measurements have been made of the reversible reaction, propylene$\rightleftarrows$trimethylene. The mixture obtained by passing pure trimethylene or propylene through a tube at a definite temperature of about 600° or 700° C. was analysed by finding the density of the product in the liquid state at −79° (*cf. supra*). The result had to be corrected for the polymerised material also formed. The equilibrium mixture consists very largely of propylene. The isomerism of trimethylene to propylene is unimolecular, and its speed is influenced by the shape of the containing vessel and the material of which it is made, though these effects decrease in magnitude with rise of temperature. The heat of the reaction at 550°—650° C. is calculated to be 63900 cals. At higher temperatures the reaction proceeds further, and carbon, methane, and hydrogen are formed from propylene.—W. O. K.

Terpin; Identification of —— in a complex mixture. Denigès. Bull. Soc. Pharm. Bordeaux, 1922, [2]. Ann. Chim. Analyt., 1922, **4**, 239—241.

The presence of terpin in a complex powder was established microchemically as follows: The powder was moistened with a drop of 85% alcohol on a microscope slide, and the liquid flowing beyond the limits of the powder and evaporating left characteristic tufts of prismatic needles of terpin hydrate. Characteristic needles of anhydrous terpin were obtained by micro-sublimation of the powder on to a drop of water hanging on the under side of a cover glass. The m.p. of the crystals was determined by floating a cover glass, on which was a sublimate of the terpin, on a bath of mercury which was gradually heated, and observing the temperature at which the initially white sublimate became transparent. The terpin was further identified by the carmine red colour which was developed when one or two drops of a 1% solution of sucrose or lævulose in 25% alcohol was added to a mixture of an alcoholic extract of the powder and concentrated sulphuric acid.—G. F. M.

Terpenes, phytosterols, and resins. I. Amyrin; Extraction of amyrin. K. A. Vesterberg. Annalen, 1922, 428, 243—246.

A bibliographical and historical note.—C. K. I.

Terpenes, phytosterols, and resins. II. Separation of α- and β-amyrin; Preparation of α-amyrilene. K. A. Vesterberg and S. Westerlind. Annalen, 1922, 428, 247—251.

Details are given for the preparation of crude amyrin, $C_{30}H_{49}OH$, for its separation into α- and β-amyrin by fractional crystallisation of the benzoates, and for the preparation of α-amyrilene, $C_{30}H_{48}$, by the action of phosphorus pentachloride on α-amyrin.—C. K. I.

Odour; Relationship of —— to molecular structure. R. Delange. Bull. Soc. Chim., 1922, 33, 589—630.

A general survey of the subject dealing with various theories which have been put forward and attempts to apply methods of quantitative measurement. A bibliography is given.—H. J. E.

Anthracene series. Barnett and Cook. *See* IV.

PATENTS.

Condensation products of formaldehyde and phenols; Process for the preparation of water-soluble alkali salts of ——. H. Bucherer. G.P. 350,043, 12.9.18.

The resinous condensation products of phenols and formaldehyde are dissolved in less than the equivalent quantity of alkali, the amount depending on the use to which the salts are to be put, and the solid alkali salts are salted out as a solid or soap-like mass by known methods. With the equivalent or greater quantities of alkali a solid salt cannot be salted out. The compounds are soluble in water, but the solutions are decomposed by carbon dioxide, or, on heating, with partial precipitation of the condensation product. The salts find application in the textile industry.—A. R. P.

Acetyl chloride and its homologues; Process for the preparation of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 350,050, 3.2.20.

Acetic acid, its anhydride, or an anhydrous acetate, or homologues of these substances are heated with benzoyl chloride to a temperature above the boiling point of the required aliphatic acid chloride. As by-products, benzoic acid or benzoic anhydride, together with hydrochloric acid or sodium chloride, are produced.—A. R. P.

Fatty acids; Process for the preparation of —— from hydrocarbons. W. Mathesius. G.P. 350,621, 11.3.16.

Hydrocarbons are heated to a high temperature under pressure with water and oxygen or gases containing oxygen, preferably in the presence of alkalis or alkali carbonates to prevent further oxidation of the fatty acids. Catalysts may be used to increase the yield which, under favourable conditions, is about 60%.—A. R. P.

Diethyl sulphate; Process for the preparation of ——. A. Wohl. G.P. 350,808, 31.3.18.

Ethylsulphuric acid is distilled under a high vacuum, and the more volatile by-products, e.g., alcohol, ether, and water, are condensed by cooling to -80° C., or by absorption in films of cold concentrated sulphuric acid. Diethyl sulphate, under these conditions, distils at about 110° C., even from ethylsulphuric acid containing an excess of sulphuric acid, without the formation of substitution or oxidation products.—A. R. P.

α-Chlorocrotonaldehyde; Process for the preparation of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 351,137, 18.12.20.

Crotonaldehyde is treated with chlorine and the αβ-dichlorobutyraldehyde produced is treated with water, the solution neutralised with lime, and the α-chlorocrotonaldehyde formed is distilled in steam, dried, and rectified. It is a colourless liquid boiling at 147°—149° C. and may be used for the preparation of butyrochloral hydrate.—A. R. P.

Ethers of homologues of hydroxybenzyl alcohols containing methyl groups attached to the nucleus [linseed oil substitutes]; Process of making ——. M. Melamid. G.P. 352,003, 28.4.20.

Solutions in 20% caustic soda of the hydroxy alcohols made from *m*- or *p*-cresol or technical cresol mixtures and formaldehyde are heated to 100° C. with allyl or vinyl bromide. The product is diluted with water and the solution extracted with ether or acetone. After distillation of the latter a viscous, light brown liquid is obtained which rapidly dries in the air and may be used as a substitute for linseed oil.—A. R. P.

Oxalic acid; Process for the preparation of —— from leached tan bark. A. Wipfler. G.P. 352,576, 2.10.20.

The residue from extracting pine bark for tanning purposes is transferred while still hot from the extraction apparatus and allowed to absorb as much of a hot mixture of potassium and sodium hydroxides as possible. The resulting mass is dried while vigorously stirring and slowly heated for 1 hr. to 220° C., then for ½ hr. to 240° C. The cold mass is leached and the oxalic acid present extracted by known methods. The yield is about 70—90% of the dry bark after extracting the tannin.—A. R. P.

Colloidal silver halides; Production of solid ——. J. D. Riedel A.-G. G.P. 352,656, 16.5.19. Addn. to 350,097.

Colloidal silver halides, prepared as described in G.P. 350,097 (J., 1922, 392 A), are converted into the solid state by precipitation with organic solvents—A. B. S.

Arylsulphonic acid esters of halogenated aliphatic alcohols; Process for the preparation of ——. G. von Kereszty and E. Wolf. G.P. 353,195, 29.5.19. Conv., 24.3.19.

Into a cold solution of the arylsulphonic acid chloride in the halogenated alcohol a concentrated solution of caustic alkali is stirred, drop by drop, until, after vigorous shaking, the alkaline reaction still persists. Benzenesulphonyl chloride and glycolchlorhydrin when treated in this manner yield chloroethyl benzenesulphonate, b.p. 184° C. at 8—11 mm.—A. R. P.

Formaldehyde; Manufacture of ——. The Barrett Co., Assees. of G. C. Bailey and A. E. Craver. E.P. 163,980, 16.3.21. Conv., 26.5.20.

See U.S.P. 1,383,059 of 1921; J., 1921, 637 A.

Silver alcosols; Process for production of —— *with aid of organic bodies.* Soc. Chim. Usines du Rhône. E.P. 173,733, 2.9.21. Conv., 5.1.21.

See U.S.P. 1,413,151 of 1922; J., 1922, 438 A.

Vinyl halides; Manufacture of ——. H. Plauson. U.S.P. 1,425,130 8.8.22. Appl., 13.1.21.

See E.P. 156,117 of 1920; J., 1922, 436 A.

Phosphoric esters; New liquid —— *and processes of making same. New mixed phosphoric esters and processes of making same.* A. L. Laska and H. H. C. Prillwitz, Assrs. to Chem. Fabr. Griesheim-Elektron. U.S.P. 1,425,392–3, 8.8.22. Appl., 12.4.21.

See E.P. 181,835 of 1921; J., 1922, 647 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patents.

Photography; Multicolour screens for ——. J. H. Christensen. E.P. 163,311, 12.5.21. Conv., 15.5.20.

Decrease in brilliancy and clearness on mordanting the dyes of a multicolour screen is avoided by comminuting (*e.g.*, emulsifying) liquids containing dye and mordant in such a form that precipitation does not take place, so that mordanting occurs only after the particles of liquid have been applied to the underlayer and dried. The underlayer consists of a basic cellulose derivative, such as collodion containing a little soap.—W. C.

Colour kinematography. R. O. P. Humphery and C. H. Friese-Greene. E.P. 183,150, 4.11.21.

Different sections of panchromatic or colour-sensitive film are exposed alternately through a special moving shutter to white light with a colour phase on the blue side of the spectrum and to coloured light on the red side of the spectrum. The area of the colour phase is less than that of the white light, and the density of the red colour filter should preferably diminish from one end of the filter to the other.—W. C.

Tricolour photography; Method of producing photographic plates for indirect ——. E. A. Lage. E.P. 183,189, 19.3.21.

Three silver halide emulsion films, each sensitised for different spectrum colours, are superimposed directly upon each other and brought into optical contact by expressing the intervening air from between the films by the pressure of spring-actuated or yielding rollers.—W. C.

Photographic plates; Process for preparation of ——. H. Schreiber. G.P. 350,658, 24.5.21.

Plates which can be developed in fairly bright light without treatment with an aqueous solution of desensitiser are prepared by treating the dry, exposed plate, before development, with an alcoholic solution of Phenosafranine. On drying, a thin film of desensitiser forms on the surface, and on contact with water it reacts with the silver bromide in the film. The sensitiveness of the plate is so reduced that further treatment can be carried out in moderately bright light.—W. C.

Photographic material for production of positives. H. Schreiber. G.P. 350,659, 24.5.21.

A silver-emulsion layer, the sensitiveness of which is lowered by addition of desensitisers is placed on a suitable support (glass, celluloid, or paper). On this coating is placed a transferable emulsion coating of high sensitiveness. The combination is exposed and the upper film can be developed without the lower layer being affected. From the negative so obtained, a positive is produced in the lower coating by a second exposure, and the two films are then separated.—W. C.

Multicoloured screen-plates; Process for the preparation of ——. F. W. May. G.P. 351,763, 22.3.21.

To a film support covered with a gelatin layer a coating is applied warm, in the form of lines. The film is hardened and coloured in the free spaces, the surface is treated with formalin, ferric chloride or aluminium acetate; the cover film is then washed off and the process repeated for the other colours. Printing-oil colours, removable by benzene, are used for the cover layer. The screen on a celluloid base is coated with a colour-sensitive emulsion, and is then ready for use.—W. C.

[Photographic] transfer films. Farbenfabr. vorm. F. Bayer und Co. G.P. 351,904, 13.8.20.

Paper is coated with hardened gelatin or other colloid (glue, fish-glue, casein), and a rubber film, and then with a photographic emulsion, so that the microscopic projecting fibres of the paper cause the transferable film to adhere in the developing, fixing and washing baths. The paper is exposed, fixed and washed like an ordinary plate. After drying, the negative is cut round the edges and one corner is cracked, after which it becomes detached from its support, and can be easily removed. For hardening the gelatin, formalin or potash alum can be used in addition to chrome alum.—W. C.

[Photographic] brown-tone printing-out emulsions. Farbenfabr. vorm. F. Bayer und Co. G.P. 351,905, 8.3.21.

Brown tones are obtained by adding an element of the sulphur group to the prepared emulsion and fixing in an ordinary acid fixing bath. In the case of collodion emulsions a solution of sulphur in carbon tetrachloride is added; to gelatin P.O.P. emulsions is added a solution of sulphur in carbon tetrachloride together with an oil. Selenium and tellurium have the same action.—W. C.

Tungstic acid; Production of non-phosphorescent, highly fluorescent compounds of —— *[for X-ray photography].* E. Tiede. G.P. 353,075, 14.5.20.

Non-phosphorescent, highly fluorescent compounds of tungstic acid, particularly alkaline-earth compounds, are prepared by using tungstic acid of high purity, made by repeatedly crystallising ammonium paratungstate, and precipitating with pure nitric acid. By the use of non-phosphorescent compounds intensifying screens are obtained which are superior to those ordinarily used both for visual examination and for the production of radiographs. —A. B. S.

[Photographic] transfer films; Process for preparation of ——. Mimosa A.-G. G.P. 354,294, 21.9.20.

On a temporary support is laid a collodion film containing rubber or resins, to which the sensitive emulsion is applied either directly or with a reinforcing layer. By this method gelatin, baryta, cellulose-ester film, etc. can be used as substrata instead of rough paper.—W. C.

[Photographic] fixing-bath; Regeneration of ——. P. Orywall. G.P. 354,295, 29.4.19.

Molecular quantities of alkaline-earth sulphides and anhydrous sodium carbonate, together with

2—5% of paraformaldehyde are added to the fixing-bath, in amount corresponding to the silver content of the latter. The silver is precipitated and the bath regenerated. This method has advantages over the use of sodium sulphide.—W. C.

Colour-photography; Process for atomising colloids, with exception of soaps, free from bubbles, for preparation of colour screens for use in ——. M. Obergassner. G.P. 354,389, 7.5.14.

Colloid solutions are atomised by means of such gases or vapours as are soluble in the colloid or colloid solution.—W. C.

Photographic plates. K. Wiebking. G.P. 354,432, 15.2.21.

To the glass side of plates is applied a coating containing a desensitiser, such as Safranine, the coating being soluble in cold water, or capable of yielding up the desensitiser to water. When the Safranine has dissolved the exposed plates can be developed in bright yellow light.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Cellulosic colloids; Method of controlling the stabiliser content of ——. G. Rocker, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,424,212, 1.8.22. Appl., 17.12.20.

The colloid is washed with a solution containing the stabiliser and afterwards with a liquid in which the stabiliser is insoluble, but which is miscible with the solvent in which the stabiliser is dissolved.—H. C. R.

Cartridge for blasting with liquid air and process for producing the same. A. Kowastch. U.S.P. 1,424,488, 1.8.22. Appl., 19.7.20.

Peat is combined with the usual components of a cartridge for blasting with a liquefied gas.
—H. C. R.

Solvents; Recovery of —— from the raw material for smokeless powder etc. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 307,077, 26.9.17.

The material is stored with charcoal. The volatile solvents are absorbed by the charcoal and can be recovered from it by known distillation processes. The process has the advantage of great simplicity.
—H. C. R.

Nitrocellulose; Process for dissolving ——. Köln-Rottweil A.-G. G.P. 352,905, 27.11.18.

Mixtures of benzene with methyl alcohol, to which in certain cases small quantities of gelatinising agents, such as acetone, amyl acetate, pyridine, and nitrobenzene, are added, are used instead of the customary benzene-alcohol mixture. The above gelatinising agents may also be added to mixtures of benzene and ethyl alcohol, after which nitrocellulose can be completely dissolved in the mixtures. These solvents are of value in the manufacture of powders and of artificial silk.—H. C. R.

Detonating caps for mining and military purposes; Process for the manufacture of ——. W. Friederich. U.S.P. 1,424,462, 1.8.22. Appl., 15.12.20.

See E.P. 138,083 of 1920; J., 1921, 100 A.

XXIII.—ANALYSIS.

Nephelectrometer; The ——. I. N. Kugelmass. Comptes rend., 1922, 175, 343—345.

Changes in the degree of aggregation of a colloidal solution may be observed by determining the variations in its degree of transparency. The apparatus consists essentially of three parts—an electric lamp, a vessel to contain the solution, and a thermopile. The lamp, which gives weak but constant illumination, is placed in a metal box, the interior of which is blackened, and when coloured solutions are being examined the light is filtered to render it monochromatic. A lens is interposed between lamp and solution to obtain a parallel beam. The vessel containing the solution has parallel sides which are provided with circular transparent areas through which the light may pass. An aperture furnished with a ground stopper serves for the introduction of the solution to be examined. The diameter of the sensitive portion of the thermo-electric cell is of the same size as the transparent portion of the vessel. The apparatus is standardised by filling the vessel with distilled water and determining the number of seconds required to obtain a deviation of the needle of a millivoltmeter through 100 divisions. The colloidal solution is then placed in the vessel, and the deviation of the needle for the same number of seconds is noted. The variation in transparency can thus be measured quantitatively.—H. J. E.

Extraction medium [e.g., ether]; Recovery of a volatile —— in laboratory practice. A. B. Pichler. Chem.-Zeit., 1922, 46, 698.

If a large bulk of material has to be extracted with ether, or other expensive solvent, an economy is obtained by placing a thimble with its contents, after extraction, in a boiling tube and substituting this for the flask of a Soxhlet containing a fresh thimble. After boiling for 10 mins. in a water bath the ether contained in the residue has all passed up into the fresh material and the extracted thimble can be removed and dried.—C. I.

Titration of acids and bases. J. L. Lizius and N. Evers. Analyst, 1922, 47, 331—341.

The theory of titration is outlined and the dependence of the hydrogen ion concentration of the end product on the nature of the salt formed is explained. A list of newer indicators with their colour changes and the p_H range over which they are applicable is given, and four mixed indicators are suggested. A table of common titrations showing the hydrogen ion concentrations at the end-points, suitable indicators, and the colours obtained at the end-points is also given. By titrating to a definite shade of colour instead of to the colour-change of the indicator, an increase in the accuracy of titration results, and certain titrations are made possible which are impracticable by ordinary methods.—H. C. R.

Electrometric titrations with mercuric perchlorate. I. M. Kolthoff. Z. anal. Chem., 1922, 61, 332—343.

Electrometric titration with mercuric perchlorate solution affords a trustworthy means of determining chlorides, iodides, bromides, thiocyanates. cyanides, ferrocyanides, formates, acetates, monochloroacetates, lactates, benzoates, and salicylates; in the cases of chlorides, iodides, and bromides the end-point is very sharp, even in very dilute solution, but the method is not applicable to mixtures of these salts. The method cannot be used for the determination of trichloroacetates, owing to the ready hydrolysis of the mercury compound formed, nor is it applicable to the salts of polybasic aliphatic acids. The mercury perchlorate solution used is prepared by neutralising perchloric acid with pure mercuric oxide; when all the perchloric acid has been neutralised the solution on treatment with an excess of sodium chloride is neutral towards dimethyl-yellow (dimethylaminoazobenzene).
—W. P. S.

Gold; Estimation of small quantities of ——, *as colloidal gold, by the colorimetric method.* J. A. Muller and A. Foix. Bull. Soc. Chim., 1922, **33**, 717—720.

The gold to be estimated should have been previously separated from other metals; a brief account of the methods of separation used by the authors is given. It is then dissolved in *aqua regia*, the excess of the reagent evaporated, the solution diluted to a concentration not exceeding 1/40 mg. per c.c. and reduced by formaldehyde in presence of alkali. It is essential that the particles in the two solutions to be compared should be of the same size; this condition is satisfied if reduction is carried out in identical circumstances. The authors' results are reliable in the case of gold separated from arsenic, antimony, tin, molybdenum, and tungsten, but not in that of gold separated from vanadium.—H. J. E.

Phosphorus in minerals and coke ash; Colorimetric estimation of ——. G. Misson. Bull. Soc. Chim. Belg., 1922, **31**, 222—225.

One g. of the mineral is dissolved in 10 c.c. of nitric acid and 30 c.c. of hydrochloric acid, the solution is evaporated to dryness, the residue dissolved in concentrated hydrochloric acid and treated with successive quantities of pure nitric acid until free from all traces of chlorine. The residue is finally dissolved in 25 c.c. of nitric acid (sp. gr. 1·20), and the solution treated with 10 c.c. of permanganate solution (8 g. per litre) and boiled for 2 mins. Any precipitated manganese oxide is dissolved by adding 10 c.c. of a solution of sodium peroxide in nitric acid (40 g. of peroxide in 1 litre of 1:9 acid), 10 c.c. of ammonium vanadate solution is added and, after boiling, 10 c.c. of ammonium molybdate. The colour produced is compared with a standard. Modifications of the method are used for minerals having a phosphorus content above 0·2% and also for coke ash. Comparison of the results with those obtained by gravimetric methods shows that the colorimetric method is reasonably accurate, especially in the case of small percentages.—H. J. E.

Hydrogen; Estimation of —— *and its separation from gaseous paraffins by means of palladious chloride.* J. A. Muller and A. Foix. Bull. Soc. Chim, 1922, **33**, 713—717.

The gaseous mixture containing hydrogen is placed in a small flask over water and brought into contact with 138 mg. of palladious chloride dissolved in 1 c.c. of water for each 15 c.c. of hydrogen presumed present. The whole is heated to 50°—60° C. until absorption of the hydrogen is complete, the vessel being shaken from time to time in order to dislodge the particles of precipitated palladium from the surface of the liquid. Heating is continued until no further deposition of palladium occurs; the time required for complete absorption is about a week. The palladium is collected and weighed; a correction for occluded hydrogen must be made, and it is stated that 0·24 c.c. of hydrogen at 0° C. and 760 mm. pressure corresponds to 1 mg. of precipitated palladium. Experimental data are given for pure hydrogen and mixtures of hydrogen with methane and ethane respectively.—H. J. E.

Patents.

Gas calorimeters. Igranic Electric Co., Ltd. From The Cutler-Hammer Mfg. Co. E.P. (A) 183,408 and (B) 183,409, 7.4.21.

(A) In gas calorimeters in which a stream of a test gas is burned in heat-exchanging relation with a stream of cooling fluid, error due to loss of heat during the heat exchange is eliminated by causing the stream of cooling fluid after it has absorbed heat liberated by the combustion of the test gas to flow in heat-exchanging relation with the incoming stream of cooling fluid before or during such absorption of heat, whereby the stream is preheated. (B) In gas calorimeters in which electrical resistance thermometers are subjected to temperatures the difference between which varies according to the heating value of the combustible gas employed, the temperature coefficients of resistance of the thermometers are adapted to vary according to the respective temperatures so that a constant relation, independent of the temperature at which the test is carried out, is maintained between the resistances of the thermometers, for a constant heating value of the combustible gas. Thus the resistance thermometers may be constructed of suitably proportioned sections of nickel and copper wires. —J. S. G. T.

Gas blowpipe burners [for use in laboratories, etc.]. H. G. Becker. E.P. 183,563, 23.4.21.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Bader, and British Cellulose and Chem. Manuf. Co. Separation of liquids from mixtures. 24,128. Sep. 6.

Buckley and Harvey. Centrifugal drying-machines. 23,946. Sep. 4.

Duckham, and Woodall, Duckham, and Jones. Annular muffle furnaces or ovens. 24,045. Sep. 5.

Fraser. 24,318. *See* II.

Hansen. 23,441. *See* VII.

Ionides. Mixing machines. 24,423. Sep. 8.

Jamieson. Apparatus for emulsifying liquids etc. 23,282. Aug. 28.

Lambert and Reed. Mixing machine. 23,758. Sep. 1.

Marks (Raymond Bros. Impact Pulverizer Co.). Pulverising apparatus. 23,451. Aug. 29.

Milliken. Apparatus for extracting dust and fume from gases. 24,179. Sep. 6. (U.S., 6.9.21.)

Povey. Machines for disintegrating and emulsifying. 23,921. Sep. 4.

Renault. Centrifuges. 23,462. Aug. 29. (Fr., 7.3.22.)

Rigby. Heating liquids or admixed solids and liquids in evaporative treatment. 23,911. Sep. 4.

Salerni. Apparatus for purifying gases etc. 23,581. Aug. 30.

Salerni. Distilling, heating, cooling, drying, evaporating etc. liquids. 23,583. Aug. 30.

Complete Specifications Accepted.

14,078 (1921). Welford. Cleansing and/or humidifying apparatus for air or other gases. (184,871.) Sep. 6.

14,152 (1921). Wade (Union Trust Co.). Regenerative furnaces. (184,877.) Sep. 6.

22,785 (1921). Oehm. Furnaces. (185,320.) Sep. 13.

23,575 (1921). Faber and Briscoe. Rotary kilns. (185,327.) Sep. 13.

26,584 (1921). Zynkara Co., and Cross. Compositions for preventing corrosion and removing incrustations in boilers etc. (185,035.) Sep. 6.

26,717 (1921). Clark, Dawson, and Dawson. Apparatus for pulverising, mixing, and grading. (185,037.) Sep. 6.

20,130 (1922). L'Air Liquide. *See* VII.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Alexander (U.S. Gasoline Manuf. Corp.). Producing hydrocarbon compounds. 23,289. Aug. 28.

Alexander. Motor spirit for internal-combustion engines. 24,340. Sep. 8.

Barker, Broadhead, and Hunt. Manufacture of combustible gases. 23,761. Sep. 1.

Barrett Co. Manufacture of coke. 23,963. Sep. 4. (U.S., 2.11.21.)

Beasley. 23,620. *See* XXIII.

Diamond. Motor spirit. 24,286. Sep. 7.

Engel and Masson. Clarifying and refining crude oils. 23,529. Aug. 30.

Farbenfabr. vorm. F. Bayer u. Co. Absorbing ethylene and its homologues. 24,410. Sep. 8. (Ger., 9.9.21.)

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of methane. 23,561 and 23,674. Aug. 30 and 31. (Ger., 4.10.21.)

Fraser. Gas-washing apparatus. 24,318. Sep. 8.

Hackford. Manufacture of gas from oil and utilising resulting gas. 23,572. Aug. 30.

Laing and Nielsen. Distillation of carbonaceous etc. materials. 23,796. Sep. 1.

Meade. Gasification of coal. 23,398. Aug. 29.

Neath. Manufacture of gas from coal and oil. 32,869. Sep. 2.

Tinker. Production of petrol etc. 24,062. Sep. 5.

Complete Specifications Accepted.

6010 (1921). Reid. Production of gas and carbonaceous materials. (185,135.) Sep. 13.

6274 (1921). Seigle. Apparatus for cracking hydrocarbon or other oils. (185,140.) Sep. 13.

14,276 (1921). Umpleby and Powers. Gas generators and/or retorts. (184,887.) Sep. 6.

15,066 (1921). Stenning, Beasley, and Minerals Separation, Ltd. Production of coal briquettes. (185,216.) Sep. 13.

19,158 (1921). Lentz. Oven for semi-coking of fuels. (166,544.) Sep. 13.

20,374 (1921). Ehlers. Refining mineral oils obtained from earth oil. (184,991.) Sep. 6.

III.—TAR AND TAR PRODUCTS.

Applications.

Thompson (Klipstein and Sons Co.). Manufacture of derivatives of carbazols. 23,361. Aug. 29.

Thompson (Klipstein and Sons Co.). Manufacture of *p*-dichlorbenzene. 23,362. Aug. 29.

IV.—COLOURING MATTERS AND DYES.

Applications.

Thompson (Atack). Manufacture of azines and hydroazines of the anthraquinone series. 23,809. Sep. 2.

Thompson (Klipstein and Sons Co.). Manufacture of sulphide dyestuffs and processes of dyeing therewith. 24,002. Sep. 5.

Complete Specification Accepted.

6063 (1921). Atack and Soutar. Anthraquinone dyestuffs. (185,137.) Sep. 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Delahaye. Manufacture of viscose. 23,657. Aug. 31.

Mourlaque and Parent. Transforming vegetable matter into paper pulp. 23,671. Aug. 31. (Fr., 1.9.21.)

Perry. Treatment of materials containing cellulose. 23,295. Aug. 28.

Plauson's (Parent Co.), Ltd. (Plauson). Treatment of cellulose etc. 23,808. Sep. 2.

Reynard, Tapping, and Thornley. Manufacture of cellulose. 23,421. Aug. 29.

Ros, and Volos Manufacture. Treatment of fibrous material. 24,281. Sep. 7.

Ryberg and Schaanning. Grinding paper pulp. 24,321. Sep. 8. (Ger., 7.3.21.)

Soc. de Stearinerie et Savonnerie de Lyon. Manufacture of cellulose ether salts. 24,153. Sep. 6. (Fr., 29.7.22.)

Vielle. Rendering materials waterproof. 24,206. Sep. 7.

Vielle. Manufacture of tarpaulins, ropes, etc. 24,207. Sep. 7.

Complete Specifications Accepted.

14,033 (1921). Schulke. Production of wool-like yarns from artificial threads. (167,458.) Sep. 6.

18,462 (1921). Soc. du Feutre. Carrotting fur and hair. (167,748.) Sep. 13.

19,951 (1921). Zellstoff-fabr. Waldhof, Hangleiter, and Clemm. Recovery of sulphurous acid and heat from the waste gases from pulp boilers. (167,171.) Sep. 13.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

British Dyestuffs Corp., Green, and Saunders. Dyeing artificial silk etc. 23,543. Aug. 30.

Calico Printers' Assoc., and Fourneaux. Mercerising and finishing fabrics. 23,328. Aug. 28.

Thompson (Klipstein and Sons Co.). 24,002. *See* IV.

Complete Specifications Accepted.

14,441 (1921). Silbereisen. Apparatus for scouring, dyeing, etc. fabrics in the piece in continuous process. (176,306.) Sep. 6.

21,557 (1921). Calico Printers' Assoc., and Nelson. Printing textile fabrics. (185,007.) Sep. 6.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Belton and Dempster. Effluent value for ammonia liquor etc. plant. 23,264. Aug. 28.

Carpmael (Buckman). Titanium complexes and method of producing same. 23,427. Aug. 29.

Germot. Manufacture of oxide of antimony. 24,362. Sep. 8.

Goodwin. Manufacture of oxides of nitrogen and nitric acid. 24,008. Sep. 5.

Hansen. Treatment of containers etc. of iron for manufacture of sodium peroxide. 23,441. Aug. 29.

Jacobson. Manufacture of anhydrous metal chlorides. 23,473. Aug. 30. (U.S., 31.5.22.)

Price. Chemical compound. 24,315. Sep. 8.

Rawson. Treatment of hydromagnesite. 23,419. Aug. 29.

Complete Specifications Accepted.

5615 (1921). Amer. Zeolite Corp. Preparation of artificial base-exchanging bodies. (159,196.) Sep. 6.

14,035 (1921). Soc. Anon. de Produits Chim. Etabl. Maletra. Continuous production of sulphates. (163,706.) Sep. 6.

14,459 (1921). Casale and Leprestre. Apparatus for the catalytic synthesis of ammonia. (185,179.) Sep. 13.

16,619 (1921). Wilderman. Processes and cells for electrolytic decomposition of alkali salts. (184,938.) Sep. 6.

18,805 (1921). Schmiedel. Manufacture of sulphuric acid. (184,966.) Sep. 6.

4435 (1922). Blanc. Separation of chlorides of aluminium and potassium present in solutions obtained in treating leucite. (176,770.) Sep. 13.

13,466 (1922). Carteret and Devaux. Production of crystalline titanium oxide. (185,374.) Sep. 13.

20,130 (1922). L'Air Liquide. Separating the elementary constituents of air or other gaseous mixtures. (184,454.) Sep. 13.

VIII.—GLASS; CERAMICS.

Application.

Grace. Separation of micaceous etc. material from china clay. 23,318. Aug. 28.

Complete Specification Accepted.

14,189 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Refining clay, especially china clay. (184,880.) Sep. 6.

IX.—BUILDING MATERIALS.

Applications.

Burt, Boulton, and Haywood, and China. Preservation of timber. 23,560. Aug. 30.

Dyson. Concrete for flooring etc. 24,113. Sep. 6.

Munro. Manufacture of cement. 23,810. Sep. 2.

Wallace. Bituminous paving-material. 23,319. Aug. 28.

Complete Specification Accepted.

19,446 (1921). Soc. de Recherches et de Perfect. Indus. Impregnation of wood. (168,045.) Sep. 13.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Cadby and Sons, and Willing. Iridescent heat bronzing on metals. 23,495. Aug. 30.

Crawshaw. Apparatus for hardening and tempering steel etc. 24,195. Sep. 7.

Elektrizitätswerk Lonza. Iron alloys. 24,176. Sep. 6. (Switz., 10.9.21.)

Elektrizitätswerk Lonza. 24,271. *See* XI.

Evans and Lewis. Recovery of tin from tin-pot skimmings. 24,433. Sep. 9.

France. Mineral washing. 23,775. Sep. 1.

Germot. Direct obtainment of antimony. 24,361. Sep. 8.

Geyer. Aluminium alloys. 23,429, 23,430. Aug. 29. (Fr., 30.12.21, 2.5.22.)

Golby (Nelson). Soldering metals. 23,522. Aug. 30.

Hansen. 23,441. *See* VII.

Heenan. Electrolytic systems for preventing incrustation and corrosion of metals. 23,684. Aug. 31.

Herbert. Testing hardness of metals etc. 24,200. Sep. 7.

Leggo. Furnaces etc. for ore roasting etc. 24,059. Sep. 5. (Australia, 19.12.21.)

Saltrick. Alloys. 24,119. Sep. 6.

Saltrick. Metals and alloys. 24,120. Sep. 6.

Vautin. Production of copper. 24,288. Sep. 7.

Vivian. Treatment of ores etc. by flotation. 23,784. Sep. 1.

Complete Specifications Accepted.

11,310 (1921). Rogers (Calorizing Corp. of America). Furnace particularly for calorizing metals. (184,839.) Sep. 6.

11,311 (1921). Rogers (Calorizing Corp. of America). Metallic alloys. (184,840.) Sep. 6.

11,786 (1921). Skelley, Merson, and Continuous Reaction Co. Manufacture of ferrotungsten and ferromolybdenum. (184,843.) Sep. 6.

11,787 (1921). Skelley, Smith, and Continuous Reaction Co. Ferrous alloys. (184,844.) Sep. 6.

15,179 (1921). Turner. Manufacture of carbon-free ferromolybdenum. (184,912.) Sep. 6.

15,655 (1921). Cammell, Laird and Co., Allan, Hague, and Middleton. Cementation of iron, steel, and ferrous alloys. (184,920.) Sep. 6.

15,968, 19,249, 20,938, and 33,100 (1921). Sulman, Tapling, Perkins, and Picard. Treatment of ores containing copper silicate. (185,242.) Sep. 13.

17,499 (1921). Carteret and Devaux. Treatment of titanium ores containing iron. (184,948.) Sep. 6.

18,034 (1921). Usines Métallurgiques de la Basse-Loire. Production of basic steel. (184,957.) Sep. 6.

18,533 (1921). Barron and Barron. Annealing and/or other heat treatment of metals. (185,277.) Sep. 13.

21,662 (1921). Rushen (A.-G. Felder-Clement). Manufacture of tungsten carbides without free carbon for use as tools etc. (185,313.) Sep. 13.

22,216 (1921). Mulligan. Readily fusible alloys. (185,012.) Sep. 6.

XI.—ELECTRO-CHEMISTRY.

Applications.

Buffard. Recuperative electrolytic cell. 23,931. Sep. 4. (Fr., 15.9.21.)

David and Dutt. Dry batteries. 24,294. Sep. 7.

Elektrizitätswerk Lonza. Applying alloys of silicon and calcium in electrolytic processes. 24,271. Sep. 7. (Switz., 10.9.21.)

Foulds and Leblanc. Copper oxide cells. 24,279. Sep. 7. (Fr., 8.9.21.)

Freeth and Munro. Electric batteries. 23,824. Sep. 2.

Genese, Minchin, and others. Electric storage batteries. 23,646. Aug. 31.

Heenan. 23,684. *See* X.

Oldham, and Oldham and Son. Galvanic batteries. 24,274. Sep. 7.

Plews. Manufacture of storage-battery plates. 23,447. Aug. 29.

Powell. Primary batteries. 23,490. Aug. 30.

Scott. Electrolytic gas-generating systems. 23,977. Sep. 4.

Complete Specifications Accepted.

6011 (1921). Reid. Electric furnaces. (185,136.) Sep. 13.

9024 (1921). Wade (Hazelett Storage Battery Co.). Manufacture of storage batteries. (185,148.) Sep. 13.

9494 (1921). Smith. Storage batteries. (160,821.) Sep. 13.

11,375 (1921). Warnon. Electric battery. (184,841.) Sep. 6.

11,890 (1921). Pehrson. Furnaces for electric heating. (162,285.) Sep. 6.

16,619 (1921). Wilderman. *See* VII.

18,126 (1921). Lodge Fume Co. (Metallbank u. Metallurg. Ges.). Cleaning discharge electrodes in apparatus for precipitating suspended particles from gases. (184,959.) Sep. 6.

23,241 (1921). Fuller's United Electric Works, and Beswick. Manufacture of storage battery electrodes. (185,023.) Sep. 6.

29,117 (1921). Hansen. Electric furnaces. (171,096.) Sep. 13.

XII.—FATS; OILS; WAXES.

APPLICATION.

Dubuis. 23,693. *See* XX.

COMPLETE SPECIFICATIONS ACCEPTED.

14,413 (1921). Bolton and Lush. Regeneration of fuller's earth, charcoal, and like purifiers of fats and oils and of catalysts used in hydrogenating fats and oils. (185,174.) Sep. 13.

15,856 (1921) and 580 (1922). Maypole Margarine Works, and Michelsen. *See* XIX.

16,239 (1921). Feeny (Title Guarantee and Trust Co.). Treatment of fish and other oils. (185,247.) Sep. 13.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Girvan. Heat resisting paints etc. 24,043. Sep. 5.

Gundlach. Paint etc. kneading and mixing machines. 24,370. Sep. 8.

Holzapfel. Manufacture of coating-composition, paints, or varnishes. 23,673. Aug. 31.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of oil colours and printers' inks. 23,262. Aug. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

18,479 (1921). Lorival Manuf. Co., and Drummond. Condensation of phenolic bodies with aldehydic compounds. (184,961.) Sep. 6.

20,170 (1921). Heinemann. Production of artificial resins. (184,984.) Sep. 6.

21,133 (1921). Ormiston. Metallic paint or coating. (184,999.) Sep. 6.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Love and Robertson. Substitute for vulcanite etc. 23,877. Sep. 2.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATION.

Roth. Manufacture of sheets of gelatin etc. 24,213. Sep. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

13,091 (1921). Minton. Imitation leather etc. (184,845.) Sep. 6.

17,826 (1921). Margotton. Tanning hides and skins. (184,955.) Sep. 6.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATION ACCEPTED.

10,315 (1921). Monaco. Manufacture of nitrogenous manures. (184,833.) Sep. 6.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Geveke. Treatment of sugar-cane. 23,695. Sep. 1.

COMPLETE SPECIFICATION ACCEPTED.

7962 (1921). Young. Production of ethers of carbohydrates. (184,825.) Sep. 6.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Wooldridge. Brewing beer. 23,426. Aug. 29.

COMPLETE SPECIFICATION ACCEPTED.

13,924 (1921). Bryant. Aeration of brewers' wort etc. (184,860.) Sep. 6.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Clark, and Pearson and Co. Production of a potent preparation of vitamin A. 23,944. Sep. 4.

Gamble. Purification of sewage. 23,405. Aug. 29.

Herrero. Purification of water. 23,753. Sep. 1.

Koch and Scheib. Production of preserving-means, and preservation of meat, vegetables, etc. 24,129. Sep. 6.

Loring. Manufacture of flour. 23,999. Sep. 5.

Moss. Compound for use in making bread. 23,505. Aug. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

5615 (1921). Amer. Zeolite Corp. *See* VII.

15,136 (1921). Nielsen. Sterilising milk. (185,221.) Sep. 13.

15,514 (1921). Torrance. Manufacture of chocolate or cocoa products. (185,237.) Sep. 13.

15,856 (1921) and 580 (1922). Maypole Margarine Works, and Michelsen. Manufacture of margarine. (185,241.) Sep. 13.

XX.—ORGANIC SUBSTANCES; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Arima. Production of preparation from tubercle bacillus. 23,243. Aug. 28.

Calvert. Manufacture of substances containing a methyl radicle. 23,571. Aug. 30.

Dubuis. Manufacture of solvent for perfumery, oils, etc. 23,693. Sep. 1.

Marks (Parke, Davis and Co.). Compounds of silver iodide and protein substances. 23,448. Aug. 29.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Gevaert Photo-Producten. Photographic films. 23,360. Aug. 29. (Belg., 29.8.21.)

Roth. Colour photography. 24,214. Sep. 7.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Brown. Matches. 23,379. Aug. 29.

Segay. Explosives. 23,542. Aug. 30.

XXIII.—ANALYSIS.

APPLICATION.

Beasley. Recording gas calorimeters. 23,620. Aug. 31.

I.—GENERAL; PLANT; MACHINERY.

Pure gases; Preparation of —— by the application of the principle of the hydraulic compressor. C. Heirich. Z. kompr. u. fl. Gase, 1922, **22**, 3—7, 21—22, 43—44. Chem. Zentr., 1922, **93**, IV., 305.

Where water power is available highly compressed gases can be most cheaply obtained by allowing the water to fall down a long vertical pipe, 300—400 m. high. Air or other gas is entrained with the water, separated at the bottom in a closed receiver under a pressure equal to the head of water, and the water allowed to pass away by an ascension pipe. By the use of flue gases in place of air the gases may be separated into carbon dioxide and nitrogen in this apparatus. It can also be applied to the purification of sulphur dioxide, ammonia, hydrogen, and oxygen, also of producer-gas and the like.—C. I.

Thermal conductivity of liquids, insulators, and metals; Measurement of the ——. M. Jakob. Z. Ver. Deutsch. Ing., 1922, **66**, 688—693. Chem. Zentr., 1922, **93**, IV., 606.

A mass of the material under investigation was heated above electrically and cooled below by a liquid. Heat losses were reduced by employing a vacuum jacket. The axial gradient of temperature in the slab was measured by means of thermocouples. The thermal conductivity of toluene was 0·000443 c.g.s. unit. The temperature coefficient of the thermal conductivity of a transformer oil was found to be 3%. The thermal conductivity of aluminium containing 1·13% of impurities is given in terms of the temperature by the relation $\lambda = 0{\cdot}447 (1+0{\cdot}0012_5 t)$. The corresponding result for nickel steel containing 30·4% Ni, 0·84% Mn, 0·26% C, and 0·14% Si is $\lambda = 0{\cdot}0277 (1+0{\cdot}0017_5 t)$, and this relation was unaltered by heating to about 700° C. or cooling to −30° C. or −78° C. The value of λ was increased about 2 to 4% by cooling to −185° C.
—J. S. G. T.

Boundary lubrication. Hardy and Doubleday. *See* IIa.

Suspended matter in gases. Katz and Smith. *See* XXIII.

Patents.

Chemical reaction; Process for effecting —— in the interior of [air] compressors. M. Brutzkus. E.P. 155,776, 22.12.20. Conv., 22.12.19.

The process consists of using a compressor, or vacuum pump, to control the pressure and temperature of reacting substances, so that the reaction will take place under the most economical conditions. With this object in view, as the reaction proceeds, the piston should be moved so as to keep the pressure as uniform as possible. A gradual admission of one or more of the reacting substances is sometimes desirable, and sometimes also the addition or withdrawal of heat is required if the above conditions are insufficient. Details are given showing how the process can be applied to exothermic and endothermic reactions in which the number of molecules remains constant or is either reduced or increased. Examples are given showing how it may be used in the synthetic production of ammonia, in cracking oils, and in hydrogenation.—S. G. U.

Steam boilers; Method of preventing incrustation in ——. A. Pessi. E.P. 163,013, 6.5.21. Conv., 6.5.20.

The disincrustant is a mixture of crude pyroligneous acid (20—40%), acetates or pyrolignites of alkalis or alkaline-earths (3—6%), sodium carbonate (10—30%), and arsenious anhydride (0·5—1·5%).—H. H.

Boilers and the like; Preparation for removal of scale from —— and for preventing its formation. J. H. Dine and S. H. Sieff. E.P. 182,545, 1.4.21.

Linseed is immersed in water and the temperature raised to a little below the boiling point. A viscous liquid is produced which can be added to the boiler feed water, the quantity recommended being 1 gall. for every 1000 sq. ft. of heating surface every eight hours. It is claimed that this preparation, in addition to preventing the formation of scale, causes any scale present in the boiler to fall to the bottom and break up into a fine mud which can be easily blown off.—S. G. U.

Cooling, condensing, or heating apparatus. E. Barrs. E.P. 183,195, 6.4.21.

Mounted on a flange on the top cover of a cylindrical vessel, provided at the top with a side inlet and at the bottom with a central opening for removal of the condensed material, is a vertical cylindrical cooling chamber. This chamber is fitted with a number of loose-fitting perforated plates which are kept at suitable distances apart by a series of vertical baffle plates the breadth of which is about three-quarters of the diameter of the containing cylinder. These baffles are so arranged that they cause the ascending material to follow a spiral or alternating path through the cooler. One quadrant of each of the partitioning plates is perforated by large holes, whilst the remaining quadrants are perforated with smaller holes. Long rods, screwed at either end, pass through these perforations from the top to the bottom plates, and are kept in position by nuts binding on the top and bottom plates. A side outlet is provided at the top of the cooler, and the arrangement of partition plates, baffles, etc., is supported on a ridge at the lower end of the cooler casing. Tubes may be used instead of rods, and arrangements may be made for flooding these tubes internally with water.
—S. G. U.

Cooling a gas; Means for ——. E. Jordan, Assr. to Soc. L'Air Liquide. U.S.P. 1,425,019, 8.8.22. Appl., 17.4.22.

The gas is passed through tubes extending through the shell of a heat-exchanging apparatus from an inlet chamber to an outlet chamber, and the shell is provided with an inlet and an outlet for the cooling gas. Superposed trays within the shell are provided with openings of slightly larger diameter than the tubes. These openings receive the tubes, and liquid is delivered to the uppermost tray and withdrawn from below the lowermost tray.—H. H.

Cooling vapours expelled from a solution in a distilling plant; Apparatus for ——. Akt.-Ges. der Maschinenfabriken Escher, Wyss u. Co. G.P. 350,913, 27.6.19.

The fluid to be cooled is supplied to a heat interchanger, the walls of which are for the most part covered with cooling fluid. By means of a compressor, vapour is withdrawn from the interchanger so that the saturation temperature of the cooling fluid is sufficiently low to permit interchange of heat to occur. This vapour is then compressed and further heat interchange effected between the compressed vapour and the fluid to be distilled. In order to secure brisk circulation of the cooling medium in the heat interchanger, if desired, a tube may be arranged external to the interchanger so as to permit circulation of that part of the cooling fluid not converted into vapour.
—J. S. G. T.

Absorption tower and cooler; Combined —— [*e.g., for hydrochloric acid*]. Deutsche Ton- u. Steinzeugwerke A.-G., and F. Plinke. G.P. 353,553, 8.5.20.

In a combined absorption and cooling tower, the walls of the tubes suspended in the tower and supplying cooling water thereto are wholly or in part permeable to water. The device is applicable to all processes of absorption in which heat is liberated, *e.g.*, the absorption of hydrochloric acid gas. The acid is rapidly absorbed by the water on the external surface of the tubes and the heat liberated carried away by the water flowing inside the tubes. The hydrochloric acid solution collects in the tower and is withdrawn at intervals. —J. S. G. T.

Mixing and/or disintegrating machines. C. E. Gardner. E.P. 184,433, 1.3.21.

Inner and outer helical blades rotate concentrically in opposite directions within a trough or casing; the outer edges of the outer blades are serrated. The trough is provided with one or more fixed serrated bars of which the teeth register with the spaces between the teeth on the blades, and such bars may be adjustably or removably secured at each side of a cleaning opening in the bottom of the trough normally closed by a hinged door. The inner blades rotate at a higher peripheral speed than the outer blades, and may be de-clutched during discharge of the material. The discharge outlet may be at one end or in the bottom of the trough and an outlet for continuous discharge may be provided in one end of the trough above the axis of the blades. Radial arms on the shaft of the blades may carry scrapers to remove material from the end walls of the trough and wings to sweep the material back to the outlet.—H. H.

Mixing solid materials with liquids; Method and apparatus for ——. O. D. Cunningham, Assr. to National Aniline and Chemical Co. U.S.P. 1,422,421, 11.7.22. Appl., 21.8.20.

A jacketed chamber, fitted with coils to regulate the temperature, is connected at its base with a centrifugal pump. A second opening on the side of the chamber communicates with the top of a small jacketed mixing chamber which is fitted with an agitator. The bottom of this mixer is coupled to the suction side of the centrifugal pump. Solid material is fed into the mixer, and the reaction products are forced by means of the pump into the cooling chamber, from which they can flow by gravity back to the mixing chamber. When the reaction or mixing is completed the products can be delivered from the pump direct to a receptacle. —S. G. U.

Mixing solid materials and treating the same with gases; Apparatus for ——. [*Roasting zinc blende.*] H. Reinhard. G.P. 352,657, 21.2.20.

The substance is treated with gases, *e.g.*, air, in a rotary drum divided longitudinally by partitions into a number of compartments. Commencing at the charging end of the drum the number of compartments is increased in a series of steps and then diminished in steps towards the discharging end. The device permits the use of air at a lower temperature than is customary in roasting zinc blende with heated air.—J. S. G. T.

Drying method and means. E. F. White. U.S.P. 1,424,969, 8.8.22. Appl., 24.1.21.

A long passageway, open at both ends, is provided with means for drawing in air near one end and for discharging the air near the other end. Means are also provided for regulating the temperature of the air and, near the point of induction, for adjusting the flow of air and determining the direction of flow in the passageway and at the ends. —H. H.

Desiccation apparatus; Spray ——. H. J. Zimmermann, Assr. to R. Stutzke Co. U.S.P. 1,426,030, 15.8.22. Appl., 25.10.18.

A centrifugal fan, with its axis vertical, is mounted below a vertical drying chamber, the central axial inlet of the fan forming the bottom of the chamber. A vertical cyclone dust collector is mounted in proximity to the fan and a duct affords communication between the tangential outlet of the fan and the tangential inlet of the dust collector.—G. F. M.

Drying, evaporating, etc. substances containing or yielding free alkali or acid; Process of ——. J. Rudolf. G.P. 352,343, 18.4.19.

The substances are treated in a rotating tube the inner surface of which is provided with an adherent coating of material resistant to the action of alkali or acid. Thus potash or soda lyes may be regenerated or calcium chloride lyes calcined in a rotating tube which has been provided with a lining of nickel or bronze by the Schoop spraying process. A lead lining similarly produced is suitable for drying sodium bisulphate and for evaporating sulphite and aluminium sulphate lyes. An aluminium lining is suitable for drying vegetables, fruits, foods, and condiments.—J. S. G. T.

Evaporator. W. H. P. Creighton. U.S.P. 1,424,992, 8.8.22. Appl., 30.12.20.

A vacuum pan is heated by a steam belt disposed between transverse tube-plates connected by tubes for passage of the liquid. The steam space is divided by radial plates into chambers, each containing a group of tubes. Steam is supplied to the outer portions of these chambers, and withdrawn from the contracted inner portions.—H. H.

Evaporating liquors; Method of —— *and apparatus therefor.* W. Gensecke. U.S.P. 1,425,005, 8.8.22. Appl., 27.4.20.

A container for the liquid is arranged in heat-exchanging relation with a chamber for the heating medium, and is provided with a pipe for withdrawal of the vapour. Mixed vapour and condensed liquid are withdrawn from the chamber and are separated by a trap which is connected with the vapour pipe of the container by a passage of adjustable section. The vapours from the chamber and the container meet in this passage and are together compressed and conveyed to the heating chamber.—H. H.

Evaporating liquids; Apparatus for ——. A.-G. Kummler u. Matter. G.P. 352,849, 21.12.20.

Liquid to be concentrated enters from below into a chamber arranged at the bottom of the apparatus and passes thence through a series of vertical annular channels through which it flows in ziz-zag fashion, passing over and being heated by a number of cylindrical heating devices in the annular spaces. The concentrated liquid then passes into a central chamber and out through the bottom of the apparatus.—J. S. G. T.

Atomising process for separating and drying substances in solution. W. Salge u. Co., Technische Ges.m.b.H. G.P. 352,781, 3.6.20.

Atomisation is effected by a stream of hot air or gas passing upwards through a vertical tube, which is connected through an intervening shock-absorbing device with a fall tube, in which separated material descends and is dried and cooled by the stream of gas likewise flowing in a downward direction. The process is more especially suitable for use with substances which can be exposed to a high temperature for a short time only, and which besides must be cooled gradually.—J. S. G. T.

Evaporating (concentrating) liquids without employing a vacuum; Apparatus for ——. A. Wurm. G.P. 354,860, 23.11.18.

Bucket wheels rotate within the vessel containing the liquid to be evaporated, the vessel being preferably double-walled and heated by steam or a water-bath. The buckets are so constructed and follow one another in such manner that the liquid which is lifted up by the scoop of one bucket flows back into the vessel over the back of the opposite scoop, whereby a large surface of liquid is exposed to the atmosphere.—J. S. G. T.

Catalyst and method of preparing the same. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,425,576, 15.8.22. Appl., 8.5.20.

The product of thermal decomposition under oxidising conditions of the cyanamides of a number of metals of the type of silver and copper is used as a catalyst.—H. H.

Discharge electrodes for precipitating systems. O. H. Eschholz, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,425,637, 15.8.22. Appl., 15.2.19.

In a precipitating system, a portion of the discharge electrode extends beyond the collecting electrode and is tapered. The discharge electrode is arranged so that its narrowest part is at a greater distance than any other part from the collecting electrode. Pre-ionising means are integrally associated with the projecting part of the electrode.—J. S. G. T.

Electrical precipitation of suspended matter from electrically insulating fluids, especially gases; Process and apparatus for ——. E. Möller. G.P. 349,737, 20.7.20. Addn. to 277,091 (*cf.* F.P. 449,337; J., 1913, 495).

The protective medium used to envelop and clean the discharge electrodes is supplied in the direction of the length of the electrodes. This may be effected by means of nozzles disposed at either one or both ends of the discharge electrodes. In the latter case, the two oppositely directed streams of air impinge upon one another and are very effective in removing any deposited dust from the discharge electrodes. —J. S. G. T.

Electrical purification of gases, employing precipitating electrodes of the plate form. Metallbank u. Metallurgische Ges. A.-G. G.P. 352,901, 18.7.20.

The gas flows in the direction of the length of the discharge electrodes, and the precipitating electrodes, arranged transversely to the stream in step formation, are disposed so that gas is uniformly distributed over the slots between the plates. The corners of the plates swept by the gas stream are reduced or bevelled, and the slots are divided up into cells by means of partitions. The precipitating surface is thus increased, and the structure both in form and operation resembles the customary tubular apparatus, but effects a more uniform distribution of the gas to be treated.—J. S. G. T.

Electrical precipitating plants; Arrangement of insulators in ——. Siemens-Schuckertwerke G.m.b.H. G.P. 354,783, 12.2.20. Addn. to 332,805 (*cf.* E.P. 164,680; J., 1921, 550 a).

In an electrical precipitating plant, operated according to the original patent, a jacket extending into the high-tension field surrounds the insulator, and the bottom of this jacket projects into a wider conducting jacket extending to the other pole, or earthed. Discharge between the two jackets is prevented by suitable choice of their respective diameters and by avoiding the presence of any sharp edges and corners on the surfaces of the jackets. —J. S. G. T.

Washing insoluble powders; Apparatus for ——. P. W. Prutzman, Assr. to General Petroleum Corp. U.S.P. 1,426,099, 15.8.22. Appl., 20.8.21.

A solvent is circulated upwards through a mass of the powder contained in a shell, and means are provided for carrying off the overflow solvent from the shell.—H. H.

Charcoal; Process of producing vacua by means of ——. Verein Chem. Fabr. in Mannheim. G.P. 326,385, 15.11.17.

Charcoal used in the production of vacua is prepared from wood or similar material, which prior to carbonisation is impregnated with salts or like substances.—J. S. G. T.

Treating liquid, powdered, or gaseous materials; Rotating hollow disc for use in —— by atomising in a stream of air or gas. Metallbank u. Metallurgische Ges. A.-G. G.P. 349,844, 17.7.20.

The interior of the hollow rotating disc for treatment of material in accordance with G.P. 345,805 (J., 1922, 317 a) is divided into a number of separate compartments corresponding to the number of rings of jets employed. In this manner a number of substances, if necessary together with gases or vapours, may be centrifuged, without any mixing of the various substances occurring within the interior of the rotating disc. Separate delivery of material to the various rings of jets disposed one above another is, in many cases, necessary and advantageous, as when a gas or vapour is to be centrifuged between atomised strata of liquids or powders.—J. S. G. T.

"Molecular filters"; Process of preparing ——. G. Alefeld. G.P. 351,084, 24.1.20.

Thin coatings of precious metals, oxides, acids or combinations of these, permeable only to certain molecules, are deposited upon a permeable support. For example, a silver mirror may be produced on the support or coatings may be produced according to the process practised in the ceramic industry for the production of lustres. Filters so prepared may be used as dialysers, or, if the support is an earthenware cylinder, may be used in centrifugal machines for separating chemical compounds or mixtures. Solutions of cuprammonium artificial silk, *e.g.*, may be freed from copper compounds, the latter passing through the filter, and then yield filaments which are stronger than those from which copper has been removed by a chemical process. —J. S. G. T.

Drum filters; Process of and apparatus for operating ——. G. Polysius. G.P. 353,135, 24.7.20.

Part of the sludge in the filter trough is periodically or continuously removed and distributed over a part of the filtering surface which is not immersed in the sludge. The sludge overflows or is run off or sucked from the trough and is delivered to a compressed air siphon, or alternatively the siphon itself may open into the trough.—J. S. G. T.

Crystals; Continuous process for producing well-formed, uniform —— from solutions. A.-G. der Chem. Produkten-Fabr. Pommerensdorf, and R. Siegler. G.P. 351,947, 26.7.19.

The solution to be crystallised flows through a long rotating tube of relatively small diameter surrounded by a heat-insulating jacket. The solution is cooled by a counter current of air, preferably introduced tangentially. Adherence of crystals to the walls of the tube is prevented by supplying heat to the bottom part of the space between the tube

and the jacket. The size of crystals is determined by the temperature, speed of rotation of the tube, initial concentration of the solution, depth of liquid in the tube and direction of travel.
—J. S. G. T.

Heating, evaporating, or distilling liquids or molten substances; Process of atomising and ——. A. Keller. G.P. 352,296, 9.12.20.

The apparatus consists of a heated vessel which contains only a small quantity of the material and is provided with a removable turbine device, the jacket of which is perforated or slotted. This turbine device sucks the material from the bottom of the vessel and then projects it in a finely atomised condition against the walls, so that the whole heated surface of the vessel is continuously covered with a layer of liquid. On account of the brisk circulation of liquid the thermal efficiency of the process is high, and the process more economical than those utilising a normal filling of the vessel.
—J. S. G. T.

Chemical reactions; Process of carrying out vigorous ——. Gewerkschaft des Steinkohlen-Bergwerks "Lothringen." G.P. 353,423, 25.7.17. Addn. to 349,330.

In a process for carrying out vigorous chemical reactions, and more especially for the production of salts from gases and liquids, *e.g.*, the production of ammonium salts from ammoniacal gases and acid liquids in accordance with G.P. 349,330 (J., 1922, 401 A), a portion of the liquor in the weakly alkaline section of the circuit is tapped off and completely neutralised by a fresh supply of acid. The temperature of the circulating liquor to be charged with gas is regulated in order to control the degree of saturation of the liquor with gas.
—J. S. G. T.

Acid-resisting lining for vessels. V. Zieren. G.P. 355,374, 30.6.20.

The lining is built up of a number of layers of acid-resisting material of various thicknesses, that immediately in contact with the wall of the vessel being impervious to liquid, while the inner ones are porous and take up the expansion occurring on heating. In this manner the outermost layer is better able to withstand the effects of variations of temperature.—J. S. G. T.

Kiln with heating chambers and cooling chambers. V. Gelpke, Assr. to Deutsche Evaporator-Akt.-Ges. U.S.P. 1,426,287, 15.8.22. Appl., 16.3.21.

See E.P. 179,674 of 1921; J., 1922, 490 A.

Condensers, preheaters, heat-exchangers and the like. P. Mather. E.P. 184,222, 5.5.21.

Exhaust steam; Process and apparatus for purifying and condensing —— and for purifying the condensate. M. Schull. E.P. 184,342, 6.7.21.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Short method for the ultimate analysis of ——. S. W. Parr. J. Ind. Eng. Chem., 1922, 14, 681.

The sulphur and carbon are determined by combustion of the coal with sodium peroxide in a calorimetric bomb, the carbonate formed being decomposed in a calcimeter and the carbon dioxide liberated measured. The heat evolved from the oxidation of the sulphur and the carbon is calculated, and when deducted from the total heat evolved in the combustion gives the heat liberated by the available hydrogen. This value, divided by 34,450, gives the weight of available hydrogen. The nitrogen is assumed to be constant for all coals at 1·25%, and by adding this to the quantities of hydrogen, sulphur, carbon, and ash (as determined by combustion) and subtracting from the total weight, the weight of oxygen plus combined hydrogen is obtained. The total oxygen is 8/9, and the combined hydrogen is 1/9 of this value. The total hydrogen may then be found and all the constituents of the coal can thus be determined without the usual ultimate analysis being carried out.—A. G.

Coal ash; Comparison of the standard gas furnace and micropyrometer methods for determining the fusibility of ——. A C. Fieldner, W. A. Selvig, and W. L. Parker. J. Ind. Eng. Chem., 1922, 14, 695—698.

The American Society for Testing Materials has tentatively defined the softening temperature of coal ash as the temperature at which a triangular pyramid, 0·75 in. high and 0·25 in. at each side of base, mounted vertically, has fused down to a spherical lump when heated in the reducing atmosphere of a gas furnace under definitely prescribed conditions (Proc. Amer. Soc. Test. Materials, 1920, 20, 796). Fulweiler has applied the micropyrometric method, using a heating element consisting of a platinum strip, 4 cm. long by 0·5 cm. wide and 0·008 cm. thick, held between iron rods which are connected through a spiral nichrome coil with four storage battery cells connected in series. Coal ashes showing a softening temperature below 2600° F. (1427° C.) by the gas furnace method will, in the majority of cases, give results agreeing withi 100° F. (55° C.) by the micropyrometric method i fused in a reducing atmosphere of combustion gase similar to that used in the furnace method. Some ashes show considerable differences, however, betwee the results obtained with the two methods. Ver refractory ashes, having a softening temperatur above 2800° F. (1537° C.) as determined by the ga furnace method, tend to give considerably lowe results by the micropyrometric method. In general the micropyrometric method shows a point in th fusion process at which the particles become rounde and coalesce. This point agrees fairly well with th "down point" of the cones in the other method fo ashes of low and medium fusibility (up to 2600° F. *i.e.*, 1427° C.), since such ashes form a fairly fusibl slag of short softening range. Refractory ashe form viscous slags with long softening intervals an the "down point" of the cone may be 100°—500° F higher than the fusing point as shown on th platinum strip. The micropyrometric method much quicker than the gas furnace method, and obviates the special incineration of a considerab quantity of coal. It is also much more comfortab for the operator. Owing to the discrepancies me tioned, however, it is not safe to accept this metho as an alternative one for the gas furnace metho in every case.—A. G.

Complete gasification [of coal] and carburatio Rincker processes of ——. P. Gregory. So Tech. Ind. du Gaz en France, June, 1922. G J., 1922, 159, 473—474.

A pair of generators are connected together so th the direction of gas flow may be periodically r versed for the manufacture of water-gas. Wh making carburetted water-gas a secondary supply is admitted near the top of the generat receiving air during the blow, in order to raise t temperature near the dome of the generat During the subsequent run oil is admitted at t top of the second generator. By connecting t tops of the generators with their respective wa flues the plant may be used for the complete gasific tion of coal as originally devised by Rincker (J., 1921, 73 a). The waste blow gases can be utilised for steam raising.—H. Hg.

Coal gas enrichment; Catalytic products for ——. P. Mallet. Soc. Tech. Ind. du Gaz en France, June, 1922. Gas World, 1922, **77**, 126. Gas J., 1922, **159**, 475—476.

Finely divided copper is mixed with heavy petroleum oil and the mixture heated at 600° C.; or the oil is passed through a heated retort the inner surface of which is coated with finely divided copper; the copper is alloyed with magnesium to make it more permeable. 1000 kg. of the oil yields 420 cub. m. of gas suitable for enrichment purposes, having sp. gr. 1—1·2 and calorific value 15,000 cals. (1685 B.Th.U. per cub. ft.). The gas contains about 40% C_2H_4 and practically no sulphur. The yield of spirit is 275 l., which gives the following results on distillation:—

Temp. °C.	70°	80°	90°	100°	110°	120°	130°	140°
Yield ..	3·6%	9·3%	18·4%	27·0%	38·0%	48·6%	58·4%	67·0%
Temp. °C.	150°	160°	170°	180°	190°	200°	210°	220°
Yield ..	75·1%	81·1%	86·5%	91·1%	94·6%	96·5%	98·3%	100%

The tar amounts to 184 kg.; undecomposed oil is separated from this by distillation for further use.

—H. Hg.

Gas producer; Marconnet ash-fusion —— for gasification of coke breeze. G. Rivière. Soc. Tech. Ind. du Gaz en France, June, 1922. Gas J., 1922, **159**, 424—425.

The producer is rectangular in plan and is provided with slag holes at the base. The lower portion of the vertical walls is water-jacketed and provided with openings for poking the charge and for the admission of air and steam. A number of weighted rods pass through the crown of the producer; these are lowered by gravity and raised by mechanical means in order to agitate the mass of fuel. During a test coke breeze containing from 14·8 to 34·3% of ash was mixed with limestone and iron ore and gasified at the rate of 405 kg. per sq. m. (83 lb. per sq. ft.) grate area per hour. The slag contained about 40% of silica, 21% of alumina, 34% of lime and 1—2·4% of iron. The gas contained CO_2 1·5%, CO 29%, and H_2 1·8%, and its heating value was 71·4% of that of the coke charged.

—H. Hg.

[Iron] oxides for gas purification; Valuation of ——. G. H. Gemmell. N. Brit. Assoc. Gas Managers, 7.9.22. Gas J., 1922, **159**, 471—473.

The quantity of sulphur which an oxide of iron will absorb after repeated foulings and oxidations is determined by placing 100 g. of the oxide in a glass tower up which passes a mixture of 1 pt. of air, 2 pts. of washed hydrogen sulphide, and 7 pts. of coal gas. The mixed gases are washed with water or dilute ammonia solution before entering the tower. When hydrogen sulphide escapes freely from the tower the oxide is removed, exposed to the atmosphere, and re-sulphided. After five foulings the weight and proximate composition of the spent oxide are determined. Results obtained with different natural bog ores and artificial oxides are given in detail. Tests with air-dried precipitated ferric hydroxide and with the same material heated to 100° C., 150° C., and a red heat showed that a high degree of hydration of the oxide is not essential for the absorption of sulphur. Exposure of a larger surface by mixing the oxide with sawdust did not increase the amount of sulphur absorbed.

—H. Hg.

Pyridine; Recovery of —— from coke ovens. W. Gluud and G. Schneider. Ber. Ges. Kohlentechn., 1921, [2], 93—111. Chem. Zentr., 1922, **93**, IV., 389, 513.

Pyridine suitable for denaturing alcohol can be obtained from crude benzol recovered in coke-oven works, by extraction of the first runnings with sulphuric acid. The pyridine-sulphuric acid should contain at least 20% of pyridine bases boiling under 160° C., and be practically free from resins and oils, free from other acids and salts, such as hydrochloric acid and sulphates, and practically free from iron salts. The analysis of the pyridine-sulphuric acid is carried out by evaporating 500—1000 g. for half an hour on the water bath, cooling, and making alkaline with 25% ammonia. The crude bases are separated and distilled up to 170° C. The distillate is dried with solid sodium hydroxide, separated, and re-distilled. The weight of bases passing over below 160° C. is determined.

—H. C. R.

Boundary lubrication; Temperature coefficient [of ——]. W. B. Hardy and I. Doubleday. Proc. Roy. Soc., 1922, **A 101**, 487—492.

The method previously described (J., 1922, 242 a) has been employed to measure the static friction between various clean and lubricated faces at temperatures ranging from 15° to 110° C. The physical state of the surface of glass is much altered by a relatively small rise of temperature. The friction of a face of quartz, steel, or bismuth, thoroughly freed from adherent films, is practically independent of temperature. The coefficient of friction of clean quartz is less than that of glass. In the cases of steel or quartz faces flooded with various lubricants, the friction was found to be independent of temperature. When the lubricant was solid over part of the range of temperature employed, the friction decreased with rise of temperature, becoming zero at the melting point. When the lubricant was completely melted, the friction suddenly attained a higher value than any previous value, and on the temperature being increased remained constant. When the temperature fell again, the friction remained constant until the melting point was reached, when the friction suddenly fell, but not to zero. Below the melting point the friction measured is that of the lubricant on itself, while above the melting point, the friction is that of solid faces modified by a primary film of the lubricant. When films of insensible thickness were deposited on the surfaces, the discontinuity of the friction at the melting point disappeared, the friction becoming constant over the whole range of temperature, whence it is concluded that the friction of quartz and of steel lubricated with various normal paraffins and the related normal acids and alcohols is sensibly independent of temperature. The results obtained in the neighbourhood of the melting points of the lubricants confirm the view that solid friction changes suddenly to fluid friction at a certain critical thickness of lubricating film. When lubricant is present in excess, an increase of friction may arise as the effect of surface tension.

—J. S. G. T.

Pure gases. Heirich. *See* I.

Carbon black. Neal and Perrott. *See* XIII.

Suspended matter in gases. Katz and Smith. *See* XXIII.

Patents.

Drying of lignite, peat, turf, and the like. K. W. J. H. Jacobs. E.P. 163,719, 5.5.21. Conv., 27.5.20.

The material is passed downwards through a closed chamber provided with a number of hot-air channels so arranged that the drying is effected slowly in the upper zone and more rapidly in the lower zone. The speed of drying may be controlled by varying either the quantity or the temperature of the air.

The air is forced through the channels and the material either under suction or under pressure. The dried product is suitable for coking.—H. Hg.

Coal; Art of treating —— [to obtain a smokeless fuel]. F. J. Root. U.S.P. 1,426,012, 15.8.22. Appl., 7.4.19.

Coal particles are compressed into blocks by a pressure of at least 3 tons per sq. in., applied in one direction only, and are meanwhile heated to 450° C. by surrounding retorts placed transversely to the direction of pressure.—A. G. P.

Peat, lignite, and other carbonaceous substances; Process and apparatus for the conversion of —— into artificial coal. O. A. Ford, Assr. to M. J. Thompson. U.S.P. 1,426,723, 22.8.22. Appl., 23.9.16. Renewed 4.11.21.

The material is passed through a dryer, a pulveriser, a second dryer, and a final pulveriser, all enclosed within a kiln body. A controlled mixture of air and hot products of combustion is passed through the dryers.—H. Hg.

Carbon; Production of ——. W. E. F. Bradley. U.S.P. 1,426,144, 15.8.22. Appl., 4.9.18. Renewed 15.6.22.

A hydrocarbon gas is passed, with exclusion of air, over iron oxide heated to 800°—1000° C., and the oxide is removed from the resulting mixture.
—A. R. P.

Coal briquettes; Process for producing —— without the addition of a binding material. O. Dobbelstein. G.P. 353,551, 23.2.21. Addn. to 346,242.

Coal is heated to a temperature at which evolution of volatile matter commences, and is then subjected to a high pressure. Even poor coals and mixtures of any kind of coal with fine-grained ore or furnace dust can be treated in this way.
—H. C. R.

Combustion of pulverised fuel; Process for the ——. C. E. Blyth. E.P. 184,250, 3.5.21.

An inflammable liquid such as paraffin, insufficient in quantity to prevent the subsequent diffusion of the product with air, is mixed with coal before treatment in the apparatus described in E.P. 175,301 (J., 1922, 243 A), or before or during pulverisation in other apparatus.—H. Hg.

Heat contained in the fuel residues of furnaces; Method and means for utilising the ——. J. S. Withers. From Deutsche Evaporator-A.-G. E.P. 184,211, 7.3.21.

Fuel is partly burnt on a primary grate with a mechanical feed and the residue is discharged on to a secondary grate arranged below the primary grate. Air is supplied under the secondary grate and, together with products of combustion from that grate, passes to the under side of the primary grate. All or part of the air may pass through flues in the side walls of the furnace immediately before entering the primary grate. In order to prevent passage of air to the upper side of the primary grate a horizontal wall is provided and so spaced as to permit the passage of fuel only from one grate to the other. The primary grate may be inclined and may deliver fuel to the secondary grate through an auxiliary grate which can be rocked and which has an adjustable ash passage. The air may be admitted to the grates through louvres or lateral sluices. The secondary grate may be so mounted that it can be oscillated. Part of the air required for combustion may be supplied direct to the primary grate.—H. Hg.

Gas producers. W. Climie. E.P. 184,323, 15.6.21.

The rotary air-blast cone of a water-sealed producer is composed of a number of superposed rings of double-angled cross-section spaced upon a conical framework so that slots are formed for the passage of air into the fuel bed. Each ring has projecting flanges such that when the rings are assembled the outer surface of the cone is provided with two or more continuous spiral ribs. The base of the cone is separated from the annular ash-pan by a water seal and the two may be rotated in the same or in opposite directions. An upwardly projecting blade may be fitted to the ash-pan so as to prevent formation of clinker between the lower edge of the cone and the inner wall of the generator. The cone is rotated in combination with a rake acting upon the upper surface of the fuel in the generator.
—H. Hg.

Vertical-retort gas-making apparatus. R. M. Searle, Assr. to The U.G.I. Contracting Co. U.S.P. 1,427,078, 22.8.22. Appl., 23.9.19.

A number of vertical retorts, each of which is surrounded by an independent heating chamber containing horizontal baffles, are arranged in a circle around a vertical flue which conducts the waste gases downwards to a regenerator. The combustion chamber is subdivided into a number of combustion chambers connected with the heating chambers.
—H. Hg.

Gas mixture; Continuous process for producing a —— from water-gas and the volatile matter from coal. H. Strache. G.P. 353,649, 9.2.21. Conv., 9.2.20.

The gases produced by the hot blast are led off from the middle of the gas producer through an open tube, whereas the hot-water gas is led through the annular space between this inner tube and the walls of the gas producer, which is filled with fuel. When fuel of high water content, such as lignite, is being used the hot blast gases may be burnt in the inside of the producer by passing air through a suitably arranged pipe. The hot blast gases are then passed either to the chimney or to a steam superheater. The water-gas passes through the annular space containing the fuel, carrying away the volatile matter with it through the top of the gas-producer to the gasometer.—H. C. R.

Gas washers. A. Florin. E.P. 184,060, 9.8.21.

The washing liquid is contained in a horizontal rotary casing mounted on the ends of two pipes forming gas inlet and outlet respectively, and flows in contrary direction to the gas. Two concentric perforated cylinders are fixed within the casing and rotate with it; the annular space between the cylinders is packed with washing bodies so as to present a large surface to the gas. Partitions parallel to the ends of the casing are provided with openings alternately at the circumference and at the centre so as to direct the gas along a zigzag path.—H. Hg.

Sulphur; Process for obtaining pure —— from gas-purifying materials. L. Hoffmann. G.P. 355,867, 26.2.21.

The contents of the scrubbers are extracted with a volatile solvent such as carbon bisulphide, the solution is mixed with a liquid which does not dissolve sulphur or tar and is not acted upon by the carbon bisulphide, and the latter is distilled off. An aqueous solution of a salt having no action on the substances named, and of a sp. gr. lying between that of the tar and that of the sulphur (*e.g.*, a solution of aluminium sulphate of sp. gr. about 1·3) is used. After the solvent has been

distilled off, the sulphur sinks to the bottom of the vessel and the liquid can be decanted off.
—H. C. R.

Hydrocarbons; Refining of liquid ——. A. E. Dunstan. E.P. 184,281, 12.5.21.

To remove sulphur compounds, liquid hydrocarbon oils are subjected to a preliminary treatment with liquid alkali, then agitated with an alkali hypochlorite solution, such as sodium hypochlorite, containing free alkali, and finally treated again with liquid alkali. The preliminary alkaline treatment removes some sulphur compounds and acidic compounds which would decompose the hypochlorite, whilst the final treatment eliminates the greater part of the sulphur compounds oxidised by the hypochlorite and not removed by it.—F. G. P. R.

Distilling [oils]; Process and apparatus for ——. J. T. Fenton. U.S.P. 1,424,998, 8.8.22. Appl., 29.3.21.

A still for use in topping oils is constructed with a bottom in the form of descending steps down which the oil flows in a thin stream. A weir at the top of the steps, having a vertically movable gate over which the oil flows, forms a preheating reservoir, whilst at the bottom is situated a well in which the depth and temperature of the oil are made to regulate valves on the oil inflow pipes leading into the preheating reservoir.—F. G. P. R.

Retort furnace and condensing apparatus for the eduction of oil and fuel gas from oil shales and sands. C. L. Buckingham. U.S.P. 1,425,074, 8.8.22. Appl., 1.2.21.

A horizontal retort of U-shaped cross-section is provided along its sides with longitudinal flanges which rest on brickwork walls composing the flue. A cover to the retort is provided with a number of gas domes with outlet pipes to condensers. The shale or sand is fed in at one end of the retort and continuously moved along to the other end by suitable means, such as a screw conveyor.
—F. G. P. R.

Motor fuel. F. W. Rohrs. U.S.P. 1,425,135, 8.8.22. Appl., 23.2.21.

A liquid fuel for internal-combustion motors is composed of 88% of a light petroleum distillate, 9% of benzol, and 3% of acetone to act as an oxygen carrier.—F. G. P. R.

Transformer oil; Process of purifying and dehydrating ——. C. H. Hapgood, Assr. to The De Laval Separator Co. U.S.P. 1,425,645, 15.8.22. Appl., 3.5.21.

Transformer and similar oils containing only a very small proportion of water are practically completely dehydrated by being subjected to centrifugal force whereby the water is carried to the periphery of the machine and there held as a surrounding film. The oil floats on the watery envelope thus formed and is drawn of at a point closer to the axis of rotation than the inner wall of the water film.—F. G. P. R.

Petroleum; Distilling —— *under high pressure.* C. E. Stockford, Assr. to Standard Oil Co. of New York. U.S.P. 1,425,712, 15.8.22. Appl., 8.5.15.

The fire chamber and flue beneath a horizontal, high-pressure still are so arranged that the whole length of the still bottom is exposed to direct flame and fire gases. The distance between the bottom of the still and the top of the furnace bridge wall should be more than one third of the diameter of the still.—F. G. P. R.

Hydrocarbon oils; Process of treating ——. *Mineral-oil derivatives.* H. T. Maitland, Assr. to Sun Co. U.S.P. 1,425,882–5, 15.8.22. Appl., 15.4.19.

(A) An organic acid insoluble in water and capable of being saponified is made from petroleum oil by subjecting a heavy distillate, such as lubricating oil stock, to treatment with sulphuric acid and separating the acid sludge. The remaining oil is treated with alkali and the latter run off and acidified with a relatively weak acid whereby the alkali soaps are decomposed and insoluble organic acids liberated. (B) Acid sludge is agitated with a continuous supply of fresh hot water until the free acid content of the sludge is sufficiently reduced to leave the water-insoluble saponifiable oil described in (A). (C, D) The insoluble saponifiable organic acids described in (A) and (B) are claimed as new compounds, one being liquid and the other solid at ordinary temperatures. They are insoluble in water, practically odourless, do not become rancid and contain less than 1% of sulphur. They are readily saponifiable to substances soluble in water in all proportions and in mineral oils totally and partially respectively, and as such have the characteristics of soaps derived from animal and vegetable oils.—F. G. P. R.

Hydrocarbons; Process of producing light ——. C. R. Burke, Assr. to L. P. Burke. U.S.P. 1,426,149, 15.8.22. Appl., 16.1.12.

Heavy oil is distilled under atmospheric pressure and the vapours led into a compressor where they are subjected to a pressure sufficient to raise their temperature to that at which cracking takes place. By varying the pressure the degree of cracking can be regulated and a product of any desired specific gravity and character can be obtained at will.
—F. G. P. R.

Hydrocarbons; Process for the production of low boiling point ——. J. C. Black. U.S.P. 1,426,813, 22.8.22. Appl., 12.12.19.

Oil is heated in a tube still to cracking temperature and under a pressure of not less than 35 atm. whereby vaporisation is prevented. The heated oil is then passed into a larger chamber, kept completely filled with oil and under the same pressure as the still, wherein carbon is deposited, and thence passes to an atmospheric-pressure still where the light portions vaporise and are led to condensers. The heavier unvaporised portions are returned, together with fresh oil, to the cracking still.—F. G. P. R.

"Bath-oil"; Method for the recovery of —— *in the production of oils from peat.* Hochofenwerk Lübeck A.-G. G.P. 353,206, 25.5.21.

After distilling off the peat oils, the residue is mixed with tar and distilled to pitch. "Bath-oil" and anthracene oil distil over, and are subsequently separated by distillation. After drawing off the pitch, the anthracene oil together with the bath-oil may be run into the distillation vessel before charging it with peat, and the anthracene oil distilled off. On account of the recovery of the bath-oil only a small addition of foreign high-boiling oil is required in the process. The pitch produced is of good quality.—J. B. F.

Aluminium chloride; Separating —— *from heavy hydrocarbons.* C. O. Hoover, Assr. to The Hoover Co. U.S.P. 1,426,081, 15.8.22. Appl., 3.4.22.

To recover aluminium chloride from heavy hydrocarbon oils, *e.g.*, after it has been used as a catalytic agent in cracking, the product is dissolved in a suitable solvent and the mixture subjected to sublimation.—F. G. P. R.

Emulsifying agent for liquids insoluble in water. K. Daimler, and Farbw. vorm. Meister, Lucius, und Brüning. G.P. 352,860, 21.11.20.

The oxidation products obtained by treating fossil minerals of vegetable origin, such as coal or lignite, with nitric acid and air are treated with alkalis, ammonia, or sodium carbonate so as to form 5%—30% pastes and then stirred with the material to be emulsified, for example, paraffin oil, lubricating oil, castor oil, linseed oil, tar, or creosote. The emulsions obtained can be diluted and used as lubricants, water-soluble boring oils, disinfecting or other paints or adhesives.—H. C. R.

Fuel supplied to furnaces or the like; Drying ——. W. R. Wood. U.S.P. 1,427,045, 22.8.22. Appl., 25.3.19.

See E.P. 124,314 of 1918; J., 1919, 312 A.

Combustible gas; Process of producing —— and for carbonising coal. H. L. Doherty. U.S.P. 1,426,159, 15.8.22. Appl., 7.9.18.

See E.P. 132,488 of 1919; J., 1920, 684 A.

Oil stills; Damper control for ——. J. Primrose, Assr. to Power Specialty Co. U.S.P. 1,425,896, 15.8.22. Appl., 16.9.20.

See E.P. 176,100 of 1920; J., 1922, 284 A.

See also pages (A) 743, *Dehydrating emulsions* (G.P. 354,202). 747, *Fire-extinguishing etc.* (G.P. 355,107). 786, *Ichthyol oil* (E.P. 184,292). 791, *Calorific value of gas* (E.P. 184,025); *Gas analysis apparatus* (E.P. 184,279).

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Retorts or furnaces [for distilling shale etc.]. J. P. B. Webster. E.P. 184,040, 20.7.21.

The shale etc. is fed, *e.g.*, by a valved hopper, to the trays, buckets, or the like of an endless conveyor which travels through a long casing open at the ends and heated throughout its length. The casing is sealed, *e.g.*, by water seals, at each end to prevent ingress of air and escape of vapours, and may be heated by flues above and below it, through which pass gases from a combustion chamber communicating with the lower flue through openings fitted with adjustable dampers. Spaced diaphragms, extending close to the trays etc., may be provided to divide the casing into compartments, some or all of which may be fitted with pipes leading to condensers.—H. H.

Wood products; Method and apparatus for obtaining —— [by destructive distillation]. E. Berthelon. U.S.P. 1,426,346, 22.8.22. Appl., 31.12.19.

The gases arising from the destructive distillation of wood are, while still hot, passed into a receiver, from which the air has been removed, where they meet a stream of water, whereby they are cooled and the condensable products are collected. The gases are then passed through a second vessel where the acidic constituents are extracted by means of alkalis; they then pass upwards through a column where they are again washed by a stream of descending water.—A. R. P.

Absorbent charcoal for gas masks; Method of preparation of ——. Chem. Werke Carbon G.m.b.H. G.P. 310,021, 15.1.18.

Coal, anthracite, or lignite in small pieces is treated at a red heat with slightly superheated steam, extracted with mineral acid, washed with water, dried, and heated strongly. The steam treatment may be discontinued before the end of the first heating, and there may also be a preliminary heating at a lower temperature, *e.g.*, 400° C., with or without steam.—C. I.

Charcoal; Process of manufacturing highly absorbent ——. Chem. Werke Carbon G.m.b.H. G.P. 310,022, 16.1.18.

Charcoal, more especially for use in gas masks, is prepared by heating coal in from three to ten times its quantity of molten caustic alkali, with or without addition of sodium chloride or other flux; the melt is washed thoroughly and the residue roasted for a long period.—J. S. G. T.

Decolorising carbon; Process of manufacturing ——. Chem. Werke Carbon G.m.b.H. G.P. 310,622, 4.5.18.

Any kind of carbonaceous matter or coal is mixed with an alkaline-earth sulphate and the mass calcined and then elutriated, the deposited carbon being extracted with acid. If desired the process is repeated. The alkaline-earth sulphate may be precipitated upon the coal employed.—J. S. G. T.

Mercury vapour lamp; Quartz ——. Quarzlampen-Ges. m.b.H. E.P. 165,081, 12.5.21. Conv., 17.6.20.

In a quartz mercury vapour lamp, the duration of the initial ignition period is reduced to 5—8 minutes by reducing the quantity of mercury employed in the lamp. This is effected as regards the cathode vessel by allowing the mercury to extend in a thin layer between the internal surfaces of the vessel and the surface of a quartz tube fused into the front wall of the vessel or inserted loosely and stayed against the inner wall of the vessel by studs or similar projections. In the anode vessel, adjacent to the point where the light-emitting tube is connected, a small cavity to contain exactly the quantity of mercury to effect ignition by tilting is formed.—J. S. G. T.

Electric lamps and the like; [Drawn wire filament for] incandescence ——. O. Oberlander and W. H. le Maréchal. E.P. 184,291, 20.5.21.

Uranium oxide, or a substance which on subsequent treatment yields uranium oxide, is incorporated with the material used for the production of drawn tungsten filaments. If desired, thorium oxide or boric acid, or both, may be also incorporated with the material. Thus ammonium uranate dissolved in very dilute nitric acid may be added to tungstic oxide so that, on reducing with hydrogen, the resulting material contains the equivalent of 0·87% of uranium dioxide. Alternatively the reduced material may contain about 0·75% of thorium oxide and 0·75% of uranium oxide. Filaments prepared from such material retain their ductility after prolonged heating at very high temperatures. —J. S. G. T.

Electric lamp with glow-discharge. J. Pintsch A.-G. G.P. 355,855, 13.12.17. Addn. to 355,288.

The lamp is filled with an inert gas with a small admixture of another gas or vapour, such as hydrogen, nitrogen, carbon dioxide, water vapour, or metallic vapours, in such proportion that the illuminating power is not affected but the disintegration of the electrodes is suppressed and the lighting of the lamp rendered easier. The additional gas may be added to the inert gas before filling or it may be evolved during use from the electrodes or from the incompletely de-gassed walls of the lamp. —A. R. P.

Tungsten wires. E.P. 163,014. *See* X.

III.—TAR AND TAR PRODUCTS.

Phosgene; Reactions of —— with benzene and m-xylene in the presence of aluminium chloride. R. E. Wilson and E. W. Fuller. J. Ind. Eng. Chem., 1922, **14**, 406—409.

Interaction between phosgene and benzene in the presence of anhydrous aluminium chloride yields benzoyl chloride and benzophenone, but no trace of anthraquinone, the production of which was the initial aim of the investigation. There are two stages in the reaction; an intermediate compound, $C_6H_5COCl,AlCl_3$ (which can be hydrolysed to give benzoic acid) is formed and this compound reacts rapidly with a further quantity of benzene, the final product being almost entirely benzophenone irrespective of change of temperature, method of mixing, ratio of reacting substances, etc. If carbon bisulphide is used as a diluent, a large part of the product can be obtained as benzoic acid owing to the slight solubility of the intermediate compound (in the diluent), which is thus removed before it can react with more benzene. With *m*-xylene phosgene yields a dixylyl ketone in which at least two of the methyl groups are in the ortho position with respect to the carbonyl group; attempts to convert this ketone into an anthraquinone derivative by oxidation were not successful.—W. P. S.

αγ-Quinolines; Preparation of ——. I. 2.4-Dimethyl-6-ethoxyquinoline: an improved method for the preparation. S. Palkin and M. Harris. J. Ind. Eng. Chem., 1922, **14**, 704—705.

The method of Mikeska, Haller and Adams (J., 1921, 75 A) was adapted to commercial needs. The reaction product is diluted with water and a current of steam passed through for ½ hr., and after cooling, and pouring off the supernatant liquid, the tarry residue is washed several times with dilute hydrochloric acid, the washings being added to the main liquid. The cool solution is treated with an excess of strong caustic soda, and after separation the aqueous layer is drawn off, and the oil distilled at 30—70 mm. pressure. The "crude base" distillate (up to about 225° C. at 30 mm.) is treated on the steam bath with an equal weight of acetic anhydride and poured into water. After filtering, the solution is neutralised with caustic soda, the precipitated base separated, dissolved in twice its weight of concentrated hydrochloric acid, and diazotised. After filtering the solution is treated with steam to decompose the diazo compounds, cooled, filtered through cotton, and neutralised. After about 1 hr. the precipitated base is filtered off, and purified by vacuum distillation and recrystallisation from hydrochloric acid solution. The pure base melts at 88°—88·5° C. (*Cf.* J.C.S., Oct.)—A. G. P.

Pyridine recovery. Gluud and Schneider. *See* IIA.

Patents.

Tar and other liquids; Process and apparatus for distilling ——. W. Glossop, L. Bradley, and R. P. Willsdon. E.P. 184,242, 2.5.21.

The interior of a still is provided with superposed plates inclined at an angle to one another, so that liquid delivered on to the top plate runs down and is delivered on to the higher part of the next plate which is inclined in the reverse direction. In this way the liquid is caused to follow a zigzag course in the form of a thin film, and when falling from one plate to the next produces a curtain of liquid through which ascending vapours must pass. By this means the latter are well scrubbed and also cause vaporisation of the light constituents of the liquid.—F. G. P. R.

Emulsions of tars and oils; Process for dehydrating ——. Badische Anilin- und Soda-Fabrik. G.P. 354,202, 20.7.18.

The emulsion is heated in a closed vessel under pressure and the water vapour removed by releasing the pressure, the heating being continued. By this means the water can be rapidly removed without danger.—H. C. R.

Amines; Manufacture of —— from phenolic compounds. W. L. Galbraith, W. V. Shannan, W. G. Adam, and N. E. Siderfin. E.P. 184,284, 13.5.21.

In the preparation of amines by heating an unsubstituted phenol with free ammonia and ammonium sulphite, the ammonium sulphite may be replaced by another ammonium salt (ammonium chloride) together with a fixed alkali sulphite such as sodium sulphite. In general, equimolecular quantities of phenol, alkali sulphite, and ammonium salt are required. Where the phenol is originally prepared by means of a caustic soda fusion process, the crude fusion product, containing the sodium phenoxide and sodium sulphite, may be used directly and the addition of an alkali sulphite omitted. For example, when 4800 g. of crude sodium-β-naphtholate melt, 2953 g. of ammonium chloride, 2617 c.c. of aqueous ammonia (sp. gr. 0·880) and 9280 c.c. of water were heated under a maximum pressure of 180 lb. per sq. inch for 14 hrs. at 170° C. there were obtained from the product, impure unchanged β-naphthol 6·6% and crude β-naphthylamine 90·6%, which gave 79·7% of β-naphthylamine purified by distillation. The process is especially suitable for the manufacture of β-naphthylamine.—A. J. H.

Aromatic alkylamino[anthraquinone] compounds; Manufacture of ——. W. N. Haworth and F. W. Atack. U.S.P. 1,426,380, 22.8.22. Appl., 19.1.20.

See E.P. 147,964 of 1919; J., 1920, 623 A.

IV.—COLOURING MATTERS AND DYES.

6.6′-Di-α-hydroxyisopropylindigo; Preparation of —— from p-cymene. M. Phillips. J. Amer. Chem. Soc., 1922, **44**, 1775—1780.

The *p*-cymene is obtained from spruce turpentine and is converted into mononitrocymene by a modification of the method of Andrews (J., 1918, 486 A). The nitro-compound is oxidised by potassum permanganate in the presence of sodium hydroxide into *o*-nitro-*p*-α-hydroxyisopropylbenzoic acid, m.p. 168° C. (corr.), which is reduced by ferrous sulphate and barium hydroxide to *o*-amino-*p*-α-hydroxyisopropylbenzoic acid, m.p. 158° C. (corr.). Condensation of the latter with chloroacetic acid gives *o*-aminoacetic-*p*-α-hydroxyisopropylbenzoic acid,

$$C(CH_3)_2(OH).C_6H_3(CO_2H).NH.CH_2.CO_2H,$$

m.p. 232·6° C. (corr.), which is transformed by fusion with potassium hydroxide at 180°—230° and subsequent oxidation of the aqueous solution of the melt by air into 6.6′-di-α-hydroxyisopropylindigo. The new dye closely resembles indigo in appearance. It gives greenish-blue shades on cotton from a hydrosulphite vat and compares rather favourably with indigo as regards fastness to light, acid, washing, and rubbing. It differs from indigo notably in its solubility in most organic solvents.—H. W.

Glucosides; Studies of ——. I. Constitution of indican. A. K. Macbeth and J. Pryde. Trans. Chem. Soc. 1922, **121**, 1660—1668.

Indican was converted by means of methyl iodide and silver oxide into the tetramethyl-derivative, and this was hydrolysed by methyl alcoholic hydrogen chloride solution to a mixture of the α- and β-forms of the tetramethylmethylglucosides possessing the ordinary butylene-oxide linking, together with certain indoxyl derivatives, including a product closely resembling the Indoxyl Brown of Perkin. The glucosides when hydrolysed by aqueous acid yielded a crystalline tetramethylglucose, readily identified as the 2.3.5.6 or butylene oxide compound. The molecule of *d*-glucose with which indoxyl is combined in indican is thus of the butylene oxide type. The optical properties of the glucoside and its behaviour towards enzymes indicate that it is a derivative of β-glucose. —P. V. M.

Pigment Chlorine GG (M.L.B.) and Lithol Fast Yellow GG (B.A.S.F.); Constitution of ——. F. M. Rowe and E. Levin. J. Soc. Dyers and Col., 1922, 38, 203—204.

Pigment Chlorine GG and Lithol Fast Yellow GG are readily obtained pure by crystallisation from glacial acetic acid, the former as yellow prisms of m.p. 224° C. and the latter as orange-yellow prismatic needles of m.p. 266° C. Analysis shows them to be isomerides having the formula $C_{13}H_{10}N_4O_4Cl_2$, and they are obtained by condensation of 2 mols. of a chloronitroaniline with 1 mol. of formaldehyde. Such condensation products of various chloronitroanilines with formaldehyde were prepared and purified by crystallisation from glacial acetic acid for comparison with the two dyes. The condensation product from 2-chloro-4-nitroaniline (m.p. 104°—105° C.) formed pale yellow needles, m.p. 282° C.; from 3-chloro-4-nitroaniline (m.p. 156°—157° C.) a yellow crystalline powder, m.p. 239° C.; from 2-chloro-5-nitroaniline (m.p. 117°—118° C.) yellow leaflets, m.p. 207° C.; from 3-chloro-6-nitroaniline (m.p. 125° C.) yellow prisms m.p. 224° C.; and from 4-chloro-6-nitroaniline (m.p. 72° C.) orange-yellow prismatic crystals, m.p. 266° C. Pigment Chlorine GG is thus derived from 3-chloro-6-nitroaniline and Lithol Fast Yellow GG from 4-chloro-6-nitroaniline. —A. J. H.

Substantive azo dyestuffs of the naphthalene series; Synthesis of ——. N. W. Woroshtzow. Ber. Poly. Iwanowo-Wosniessensk, 1921, 4, 95—108. Chem. Zentr., 1922, 93, III., 369—370.

Important direct cotton dyestuffs containing a naphthalene nucleus to which azo groups are attached in either the 1.4, 1.5, or 2.6 positions are analogous in their substantive dyeing properties to naphthaquinone compounds having :CO groups in the same positions and this suggests that the substantive dyeing properties of dyestuffs should be associated with molecular configuration rather than definite atomic groups. In these 1.5 and 2.6 azo dyestuffs, two and one azo groups are necessary respectively. One azo can be replaced by NO_2. 1.2-Compounds also show substantive dyeing properties and these are being further investigated. Naphthalene compounds analogous to benzidine are not naphthidines but naphthylenediamine and its derivatives. Substantive 1.5 dyestuffs were obtained by tetrazotising 1.5-naphthylenediamine-3.7-disulphonic acid and coupling with either naphthionic, Neville-Winther's, or H-acid. 1.5-Nitroaminonaphthalene and 1.5-naphthylenediamine also yielded substantive azo dyestuffs, but azo dyestuffs obtained from nitronaphthionic acid and 1-amino-5-acetaminonaphthalene-8-sulphonic acid had feeble dyeing properties. When coupled with naphthionic, Neville-Winther's, and H-acid, 2-amino-6-nitronaphthalene-8-sulphonic acid yielded good dyestuffs, but those similarly obtained from 2.6-naphthylenediamine-8-sulphonic acid were even better. (With K. A. Gribow).—The action of 1 mol. of HNO_3 on a solution of 2-naphthylamine-4.8-disulphonic acid in oleum (5% SO_3) at −5° to −6° C., yields a product (probably the 6-nitro compound) which could not be isolated in a pure state, but which on diazotisation in solution and coupling, yields substantive dyestuffs with marked affinity for vegetable fibres. Nitration of 2-nitronaphthalene-4.8-disulphonic acid yields mainly 2.5-dinitronaphthalene-4.8-disulphonic acid together with a small amount of the 2.6 isomer. The 2.5-acid dyes wool in bright yellow shades which are not fast to washing but which change to fast dark brown under the action of light. On reduction, 2.5-dinitronaphthalene-4.8-disulphonic acid gives 2.5-naphthylenediamine-4.8-disulphonic acid which yields, by tetrazotisation and suitable coupling, fast dyestuffs for wool and cotton. (With M. K. Besszubzew).—*p*-Nitrodiazobenzene couples with 1.5-naphthylenediamine-3.7-disulphonic acid in the 2.6 positions, but only the disazo dyestuff has an affinity for vegetable fibres.—A. J. H.

Toluidine Blue; Metachromism of ——. R. Schwarz and E. Herrmann. Kolloid-Zeits, 1922, 31, 91—94.

Toluidine Blue in aqueous solution constitutes a poly-disperse system made up of colloidal particles and molecular disperse particles. The different colouring effects (for example α-silicic acid gel is coloured blue and β-silicic acid gel red by Toluidine Blue) are due in the first place to the difference in the degree of dispersion of the adsorbent and in the second place to the electrical condition of the adsorbing surface, which is determined by the nature of the adsorbed ions. (*Cf.* J.C.S., October.)—J. F. S.

Colouring matter of Lithospermum Erythrorhizon. R. Majima and C. Kuroda. Acta Phytochim., 1922, 1, 43—65.

The violet colouring matter of shikon, the dried roots of *Lithospermum Erythrorhizon*, has been isolated in a crystalline state and is shown to be the monoacetyl derivative of shikonin, to which the constitution γ-methylpentenyl-2.5.8-trihydroxy-1.4-naphthoquinone is assigned. The latter gives a tri-acetyl, a penta-acetyl, and a dibenzoyl derivative and on heating is decomposed, giving shikazarin, which is identical with α-methylquinizarin.—W. G.

Patents.

Benzanthrone derivatives; Manufacture of ——. British Dyestuffs Corp., Ltd., A. G. Perkin, and G. D. Spencer. E.P. 183,351, 12.7.21.

Hydroxybenzanthrone is obtained by heating a mixture of benzanthrone (50 parts), anthraquinone (50 parts), alkali hydroxide (300 parts), water (50 parts), and sodium chlorate or sodium nitrate (35 parts), in an autoclave, slowly to 250° C. and then maintaining the temperature between 250° and 265° C. for 3 hours. The product is digested with boiling water and anthraquinone is removed by filtration. Hydroxybenzanthrone is precipitated from the filtrate by carbonic acid or a stronger acid. Aminobenzanthrone is prepared by gradually heating a mixture of hydroxybenzanthrone (25 parts) and ammonia (sp. gr. 0·880, 500 parts) in an autoclave to 200° C. and subsequently maintaining the temperature at 220°—230° C. for 7 hours. The product is diluted with water and filtered, whereby aminobenzanthrone is isolated as dull red crystals; unchanged hydroxybenzanthrone can be recovered by acidification of the filtrate.—H. W.

o-[Hydr]oxyazo dyestuffs. W. Herzberg and O. Scharfenberg, Assrs. to Akt.-Ges. f. Anilin-Fabr. U.S.P. (A) 1,426,189, (B) 1,426,190, 15.8.22. Appl., 5.11.21.

(A) Claim is made for the *o*-hydroxyazo dyestuff

$C_6H(2)OH(3.5.6)Cl_3.(1)N:N.(2)C_{10}H_5(1)OH(4)SO_3H$, a dark powder giving a reddish-violet aqueous solution which becomes bluish-red by addition of sodium carbonate, orange by addition of sodium hydroxide, and which yields a red precipitate when treated with acids. The dye is applied to wool after mordanting with chromium or by the metachrome or after-chroming processes and yields violet shades. (B) The *o*-hydroxyazo dyestuff $C_6H.(2)OH(3.5.6)Cl_3.(1)N:N(7)C_{10}H_4(1)NH_2.(2.4)SO_3H(8)OH$, is a dark powder giving a greenish-blue aqueous solution which becomes violet on addition of sodium carbonate, red on addition of sodium hydroxide, and reddish-violet when treated with acids. It yields greenish-blue shades on wool mordanted with chromium before or after dyeing.—A. J. H.

Acridine derivatives. G.P. 354,400. *See* XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Polysaccharides; Constitution of ——. V. Yield of glucose from cotton cellulose. J. C. Irvine and E. L. Hirst. Trans. Chem. Soc., 1922, 121, 1585—1591.

By conducting the acetolysis of cotton cellulose by Barnett's method (J., 1921, 8 T) using sulphuryl chloride as a catalyst, a 99—100% yield of pure triacetate containing no soluble sugars is obtained. For the conversion of the triacetate into methylglucoside the use of an autoclave is inadvisable. This stage is best carried out by digesting small quantities of the compound (1 pt.) for 60—70 hrs. at 125° C. with pure methyl alcohol (15 pts.) containing 0·75% of hydrogen chloride. Residual acid is neutralised with silver carbonate and the filtrate decolorised, if necessary, with charcoal. The whole of the filtrate is then evaporated to a syrup under diminished pressure, the last traces of solvent being removed at 100° C. at 10 mm. pressure by a current of dry air. A 95·5% yield of methylglucoside is obtained. Complete crystallisation is effected by dissolving in hot alcohol, standing for a few hours, and removing the solvent by distillation at 60°—70° C. The m.p., 125°—150° C., and the specific rotation of the product indicate that it is the equilibrium mixture of pure α- and β-methylglucosides. An overall yield from polysaccharide to hexose of 95·1% of the theoretical amount is obtained. The conclusion is drawn that cotton cellulose is composed entirely of glucose residues.—P. V. M.

Asbestos and cotton; Estimation of mixtures of ——. P. Heermann and H. Sommer. Mitt. Materialprüf., 1921, 39, 315—329.

A method in which cuprammonium solution is used as a solvent for the cellulose, has been found satisfactory for the quantitative analysis of technical products containing asbestos and cellulose. Microscopical examination does not yield accurate results. The loss of weight which occurred when different qualities of asbestos were ignited varied from 1·6 to 15·8%, so that mixtures of asbestos and cotton could not be estimated by the residue obtained after ignition. The well known method for estimation of mixtures of wool and cotton based on their different resistance to the action of concentrated sulphuric acid cannot be applied to mixtures of asbestos and cotton, since raw asbestos, when in contact with 80% and 1% sulphuric acid, loses 0·9—12·3% and 1·5—39·6% in weight respectively. This loss of weight is greater when the asbestos is more finely divided. Since the silica content of asbestos varies in different qualities, this was found to be an unsatisfactory measure of the asbestos present in its technical products. Cold cuprammonium solution, however, was found to attack five qualities of asbestos only to the extent of 0·1% during 24 hrs. The method of analysis finally adopted is as follows: 0·2—0·5 g. of the air-dry product is dried at 110° C. until of constant weight and the hygroscopic moisture (usually 0·5—2·4%) thereby determined. The fat content is then obtained by extraction of the dried material with ether, and afterwards the water-soluble substances such as salts, starch, etc., are removed by treatment in boiling water for 2 hrs. and estimated. The material is then immersed for 12 hrs., with frequent shaking, in 30 c.c. of a cold, freshly prepared cuprammonium solution (about 19 g. of Cu per l.), whereby the cellulose dissolves (this is usually complete in 2 hrs.) and the solution is filtered through a Gooch crucible, the residue of asbestos being then thoroughly washed with dilute cuprammonium solution, finally with dilute ammonia, and then dried to constant weight at 110° C. and weighed as pure asbestos. The filtrate is acidified with dilute sulphuric acid after the addition of salt so that the cellulose is precipitated in a form suitable for filtration in a Gooch crucible. After filtration, the residue of cellulose is dried at 110° C. and weighed. The method is accurate to about 1·5%.—A. J. H.

Cellulose; Saccharification of ——. P. P. Budnikow and P. W. Solotarew. Ber. Polyt. Iwanowo-Wosniessensk, 1921, 4, 119—128. Chem. Zentr., 1922, 93, IV., 324—325.

In the technical production of sugars from cellulose, the recovery of the sulphuric acid used and the strength of the solutions of glucose obtained are important factors. When the solution, obtained by dissolving 1 g. of Swedish filter paper in 7—8 c.c. of 72% sulphuric acid during 3 hrs., was diluted with water so that it contained not more than 3% H_2SO_4 and then heated for 2 hrs. at 120° C. in an autoclave, the concentration of the glucose solution thereby obtained was not greater than 0·6%. In similar experiments, except that the concentration of the acid in the cellulose solution was decreased by the addition of barium carbonate instead of water, it was found that with longer heating, some of the glucose formed decomposed into organic acids. In the fermentation of glucose, obtained by the action of an acid on cellulose, it is advantageous not to neutralise completely the excess of acid before addition of the yeast. By this method 85% of the theoretical amount of alcohol was obtained from paper, but a smaller yield was obtained when caustic soda instead of calcium carbonate was used for neutralising. The theoretical yield of alcohol cannot be obtained from the purest paper since, on account of hydrolysis, small quantities of non-fermentable sugars are formed. The sulphuric acid is recoverable electrolytically. In several experiments, 36·0% to 91·5% of the sulphuric acid was recovered by means of an electrolytic apparatus consisting of an earthenware vessel, containing the cathode and a solution containing 1% of glucose and 3% of sulphuric acid, which was immersed in a glass vessel containing the anode and water acidified with sulphuric acid. Using platinum electrodes, the total quantity of sulphuric acid in the system remained constant, but with carbon electrodes a small loss occurred. The total amount of glucose also remained nearly constant but about 6% was lost due to absorption by the cathode vessel and carbon electrodes. A disadvantage of the process is that about 7·215 kilowatts was required per kg. of H_2SO_4 recovered.—A. J. H.

Wood; Importance of the degree of disintegration in the digestion of ——. P. Waentig. Zellstoff u. Papier, 1922, 2, 152—155.

In investigating Bronnert's process (E.P. 170,964, U.S.P. 1,392,047; J., 1921, 808 A) for the manufacture of sulphite pulp after subjecting the wood to a preliminary treatment for 2—4 hours with 1% sulphuric acid at 115° C., it was observed that when the wood was prepared in the form of fine shavings a total physical breakdown of the fibre occurred and the cellulose subsequently obtained by the chlorination process had the brittle character of hydrocellulose, but when wood-chips were subjected to a similar acid treatment the cellulose fibre obtained was long and strong. The yields of cellulose were: from raw shavings or chips 50%, from chips previously boiled with acid, 48%; from shavings boiled with acid 41—42%. The difference between the yields from chips and from shavings is attributed to the transverse slicing of the fibres of the shavings whereby the interior of the cell-substance is exposed to the action of the acid. In spite of the above physical and chemical differences, the yield of "α-cellulose" was identical in all cases, namely 84—85%, whether from shavings or chips and whether the wood had been boiled with acid or not. The influence of the acid treatment, however, was shown in the viscosity of the viscose prepared from the cellulose, this being considerably lowered by the acid treatment to a similar extent in the strong cellulose fibre from the chips as in the disintegrated fibre from the shavings. The above peculiar behaviour of wood is attributed to the extremely heterogeneous constitution of the raw fibre, because normal sulphite-cellulose, after boiling with acid, was converted into brittle hydrocellulose and showed only 74·3% of "α-cellulose" after this treatment. Hence it is suggested that the increased chemical reactivity of the acid-treated wood is not directly connected as cause and effect, with the physical breakdown of the fibre substance.—J. F. B.

Wood pulp; Testing the degree of digestion of ——. H. Roschier. Pappers och Trävarutidskrift. Zellstoff u. Papier, 1922, 2, 184—186.

THE rate of reduction of permanganate under standard conditions is proposed as a rapid approximate measure of the degree of digestion of wood pulp and is particularly applicable for purposes of factory control. A $N/100$ solution of potassium permanganate is most suitable; this is kept in the neutral condition and acidified just before use. 2 g. of finely rasped wood pulp, or 6 g. of moist pulp squeezed out in the hand, is weighed out and rolled into a loose ball. 80 c.c. of $N/100$ permanganate is placed in a glass-stoppered bottle of 300—400 c.c. capacity, 1·6 c.c. of $N/1$ sulphuric acid is added, the ball of pulp is dropped in, the stopper is inserted, and a stop-watch is started. The bottle is shaken slowly and uniformly by hand and the liquid is kept under observation by slightly tilting the bottle. Immediately the red colour of the permanganate is discharged the time in seconds is noted. A standard temperature of 20° C. is maintained, since the rate of discharge is greatly influenced by differences in temperature. The following grades have been established: easy bleaching pulp, 70 secs.; slowly bleaching, 50—70; medium strong, 35—50; ordinary strong, 25—35; very strong and hard, 25 secs. The values have been co-ordinated with the chlorine-absorption values determined by Sieber's method (J., 1921, 382 A).—J. F. B.

Straw; Digestion of —— by the Steffen process. T. E. Blasweiler. Papierfabr., 1922, 20, 1025—1028, 1061—1064, 1101—1103.

IN a detailed test of the Steffen process for the digestion of straw, 630 kg. of rye straw was steeped in a solution of 63 kg. of caustic soda in 819 l. of water. The liquor was completely absorbed by the straw, which was then charged into a vertical digester provided with a perforated false bottom and circulation ducts. Steam was admitted at the bottom and the air expelled, then the pressure was allowed to rise quickly to 3 atm., which was maintained for one hour. On blowing off the steam, ammonia was evolved; only 10 l. of condensed water had accumulated at the bottom of the boiler. The digested straw was covered with 2500 l. of boiling water and boiled for 30 mins. under a steam pressure of 2—2½ atm. This liquor was blown out and followed by six washes of 1800 l. of hot water, each being brought to the boil and discharged under a slight steam pressure. The washed pulp discharged from the digester contained 16—17% of dry fibre, which was increased to 42% after pressing. The yield of digested pulp, calculated on dry substance, was 59·25%; it showed on analysis 60·92% of cellulose, 30·00% of pentosans, and 9·08% of lignin. This pulp did not give lignin reactions and was similar in quality to straw digested for fodder purposes. It was also suitable for paper making and could be bleached with a consumption of 12·7% of active chlorine. The Steffen process compares favourably with other processes, such as the Oexmann process, in current use for the preparation of digested straw fodder. The treatment is complete in 4—4½ hours and the total quantity of water used is 21 times the weight of the raw material or 40 times that of the pulp obtained, as against 63 and 110 times respectively in the case of the Oexmann process.—J. F. B.

Rosin sizing. R. Sieber. Zellstoff u. Papier, 1922, 2, 99—103, 134—139. (*Cf.* J., 1921, 842 A.)

WITH regard to the influence of calcium and magnesium salts on the composition of the precipitated resinates, the quantity of alkaline-earth in the precipitate is larger the longer the interval between the addition of the earth salt and that of the aluminium sulphate. The sizing efficiency of such mixed precipitates is probably less than that of precipitates formed with aluminium sulphate alone. In the presence of free sulphuric acid, aluminium sulphate has no precipitating value and the acid resin precipitates contain no aluminium. It is not perfectly certain whether pure cellulose is capable of dissociating aluminium sulphate and fixing aluminium hydroxide by colloidal adsorption. Commercial paper pulps, however, always contain inorganic constituents, generally of a basic function, which certainly can produce this result by simple chemical decomposition. Sulphite wood pulp is capable of fixing more aluminium hydroxide in this way than mechanical pulp, and beaten sulphite pulp more than unbeaten. Well-washed gelatinous aluminium hydroxide will adsorb large quantities of rosin from a fine suspension of pure rosin in water. If pure filter paper be treated with aluminium sulphate for 24 hours, then thoroughly washed and immersed in a highly dilute suspension of rosin, particles of rosin are deposited on the fibres, whereas with untreated fibres the deposition of rosin particles is barely perceptible. These particles can be seen as bright points on the surface of the fibres under the ultramicroscope, and in the case of treated fibres they are observed particularly on the fine fibrillæ. The sizing process may best be defined partly on a chemical and partly on an electro-colloidal hypothesis. The fibre and the rosin suspension may be regarded as endowed with negative charges and the aluminium hydroxide, produced by the chemical decomposition of the soap with aluminium sulphate, is positively charged. There is no direct tendency for the fibre to adsorb the rosin emulsion since both carry the same kind of charge, but the rosin emulsion and the strongly positive aluminium hydroxide have a powerful attraction to form a colloid in which the positive charge of the aluminium is predominant, and this positive complex is then discharged on the negative fibre to produce the sized pulp. No doubt the absolute and relative concentrations of the components play an important part. This hypothesis explains the importance of the trivalent ion in the sizing process. This ion is so strongly positive that it is able to reverse the charge of the rosin emulsion, carrying it over from the negative, through neutrality, to the positive side, whereas other coagulating agents, such as acids and salts of sodium, calcium, and magnesium, simply coagulate the emulsion and discharge it, without imparting to it any electro-colloidal affinity towards the negative fibre.—J. F. B.

Sulphate pulp mills; Absorption of malodorous gases in ——. C. G. Schwalbe. Zellstoff u. Papier, 1922, 2, 175—178. (*Cf.* J., 1921, 807 A.)

The principal sources of malodorous gases in sulphate (soda) pulp mills are the digesters and the soda-recovery furnaces. These furnaces discharge not only mercaptans, hydrogen sulphide, and sulphur dioxide, but also large quantities of solid dust particles, consisting largely of sodium sulphide, sulphite and other salts, in the flue gases. It is calculated that the losses of sodium salts, expressed as sulphate, in the furnace gases amount to 15—23% of the cellulose produced, and this is the principal source of loss of alkali in the process. Based on the discovery that wood or straw is an effective deodoriser of malodorous gases of an acid nature, the author proposes to pass the waste gases through a rotating horizontal or inclined cylinder filled with waste wood trimmings or other refuse from the pulp mill. In the case of straw pulp mills knotty refuse from the straw may be used for charging the cylinder. The same arrangement also serves as a trap for the solid salts in the flue gases, and the salts may be recovered subsequently by washing the wood refuse. The action of the wood is rather that of a "contact" substance than of an absorbent, and it is presumed that the mercaptans etc. become concentrated in the pores of the wood and then oxidised. The deodorisation may be assisted, if desired, by passing chlorine together with the sulphurised gases through the material. On similar lines, the gases discharged from the digesters may be passed through the wood chips stored in the silos ready for charging the digesters. The steam which passes off together with the digester gases may be condensed and the hot water used for washing the wood in the deodorisers attached to the soda furnaces.

Patents.

Wool, fur, etc.; Insecticide, more especially for protecting —— against moth. Chem. Fabr. Griesheim-Elektron. G.P. 353,682, 30.5.20.

Dichloroethane, either alone or mixed or in solution with other indifferent or insecticidal substances, is employed. The insecticide may be either strewn in powder form or dissolved in acetone or carbon tetrachloride and sprinkled over the material. It does not evaporate so quickly as dichlorobenzene and has a more pleasant smell.
—J. S. G. T.

Fulling; Method of improving and shortening the process of ——. Diamalt A.-G. G.P. 355,104, 13.10.16.

A mixture of organic colloids with inorganic protective colloids is added to the fulling liquid. Extracts of lichens and algæ, gum tragacanth, linseed, or fleabane seed mucilage etc. may be used. Their solutions are mixed with colloidal silica and dried *in vacuo*. By the addition of this colloidal powder to the fulling liquid more rapid felting and less shrinkage result, together with a marked brightening of the material. An economy in soap and soda is also effected.—H. C. R.

Fire extinguishing and prevention of the ignition of combustible matter; Process for ——. A. Eichengrün. G.P. 355,107, 15.2.18.

Ammonium bromide is used in the solid state or in solution. It may be used in conjunction with other substances utilised for the prevention of burning. It is considerably more effective than ammonium chloride and other ammonium salts, and smaller quantities suffice for impregnating textile fabrics and paper.—H. C. R.

Vulcanised fibre; Preparation of ——. J. A. Sutcliffe. E.P. 183,497, 27.1.21.

Vulcanised fibre, prepared by the zinc chloride process, shows a tendency to absorb moisture owing to the presence of zinc chloride residues. This defect is remedied, and a product obtained more suitable for use in the manufacture of machinery parts, insulators, etc., by saturating the material immediately after the "washing off" process, or even after it has been dried, with strong ammonia solution. When completely saturated, the material is removed from the bath, washed, and dried.
—D. J. N.

Waterproofing vulcanised fibre; Method of —— J. McIntosh, Assr. to Diamond State Fibre Co. U.S.P. 1,425,878, 15.8.22. Appl., 27.4.20.

Wet vulcanised fibre is immersed in a waterproofing solution until thoroughly impregnated and then dried.—F. G. P. R.

Sulphite liquor; Process and apparatus for preparing ——. D. B. Davies and E. P. Strong. U.S.P. 1,424,883, 8.8.22. Appl., 1.6.20.

Liquor from a storage tank is continuously circulated through a pipe system, and sulphur dioxide is introduced into the stream. The liquor is subsequently returned to the storage tank at or near the bottom.—D. J. N.

Cellulose; Process for the extraction of —— from vegetable fibres. B. Cataldi, Assr. to A. Pomilio. U.S.P. 1,424,620, 1.8.22. Appl., 17.5.21.

Cellulosic material, such as straw, esparto grass, jute, cotton, and the like, or wood freed from bark, is leached in a digester with alkali solutions under heavy pressure, first hydraulic then steam pressure, and is then disintegrated, and transferred to an acid-resisting digester, where it is alternately chlorinated and washed with water (to cool the mass and remove hydrochloric acid). When further chlorination ceases to cause any rise in temperature, the material, after a final wash with water, is leached with alkali solution at atmospheric pressure. The resulting product consists of practically pure cellulose.—D. J. N.

[*Artificial silk*] *threads; Process of producing lustrous* ——. C. A. Huttinger, Assr. to The Acme Artificial Silk Co. U.S.P. 1,425,654, 15.8.22. Appl., 12.6.19.

Wood pulp is saturated with caustic soda solution of sp. gr. 1·17, pressed, and treated with carbon bisulphide; the resulting xanthate is dissolved in water, filtered, and spun into an aqueous solution of a bisulphate, containing no free acid, and maintained at a temperature of 70° F. (21° C.).
—D. J. N.

Cellulose butyrate; Process of preparing ——. A. D. Little, Inc., Assees. of G. J. Esselen, jun., and H. S. Mork. E.P. 167,143, 9.3.21. Conv., 26.7.20.

In the preparation of cellulose butyrate, cellulose, 100 pts., in any form such as yarn, linters, wood pulp, paper, etc., containing 3—8% of moisture, is soaked in 1500—1600 pts. of an acetic acid solution of sulphuric acid (the latter acting as a catalyst in the subsequent esterification), having the following approximate composition by weight, sulphuric acid (sp. gr. 1·84) 1—5%, water 5—8%, acetic acid 94—87%; the impregnated cellulose is then pressed until it contains 1¼ times its weight of solution, and is treated in a bath containing, for example, butyric acid 400 pts., butyric anhydride (90%) 465 pts. by weight, the reaction, which is accompanied by a rise in temperature, being allowed to proceed until a product of the desired solubility is obtained. When sulphuric acid is used in relatively small quantities it is advisable, when the product shows good solubility in chloroform, to accelerate the reaction by the addition of, *e.g.*, 5 pts. of sulphuric acid (sp. gr. 1·84) and 3—5% (by volume) of water on the volume of the butyrating mixture. The resulting product is soluble at room temperature in methyl or ethyl alcohol containing 50—90% by volume of benzol, and in many other solvents and solvent mixtures such as chloroform, acetone, 90% carbolic acid, hot denatured alcohol, hot solvent naphtha, hot benzol, etc.—D. J. N.

Cellulose derivatives [viscose]; Manufacture of ——. H. Dreyfus. E.P. 183,882, 9.2.21.

A high molecular viscose, which may be used in the manufacture of artificial filaments etc. without previous "ripening," is made by treating cellulose or a near conversion product (1 mol. $C_6H_{10}O_5$) with not more than 2 and preferably about 1 mol. of alkali at concentrations above 15%, preferably 20—50%, and kneading the alkali-cellulose thus obtained with not more than $\frac{1}{2}$ mol. ($\frac{1}{5}$—$\frac{1}{2}$ mol.) of carbon bisulphide per molecule of cellulose $C_6H_{10}O_5$, until all the carbon bisulphide has entered into combination. The carbon bisulphide may with advantage be dissolved in a suitable organic solvent, such as benzol, in amount equal to 3 or 4 times the weight of cellulose. The solvent is subsequently recovered by any suitable method. By thus obviating the usual "ripening" process, during which the cellulose aggregate is exposed to the degrading action of free alkali, a product is obtained, which is capable of giving stronger threads than can be obtained from viscose prepared by the usual methods. —D. J. N.

Cellulose compounds [ethers, esters, etc.]; Manufacture of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 183,908, 28.4.21.

Cellulose derivatives are made by treating cellulose in a highly dispersed condition with the desired reaction components, with or without condensing agents. The cellulose is dispersed by intensive mechanical disintegration at high speeds until the particles are about 0·8 μ in diameter, *e.g.*, in the colloid mill (E.P. 179,124; J., 1922, 449 A). Cellulose phosphoric ester is made by treating 4 pts. of cotton dispersed in water as described above, with 2 pts. of orthophosphoric acid at a gradually increasing temperature (30°—50° C.), until esterification takes place, as shown by the appearance of foam. The reaction is preferably carried out *in vacuo*, and 0·1 pt. of concentrated sulphuric acid may be added as an accelerator. Cellulose acetate is obtained by heating 100 pts. of highly dispersed cellulose, pressed until it contains only 20—30% of water, with 30 pts. of acetic anhydride and 120 pts. of acetic acid, until esterification takes place with vigorous foaming. Cellulose sulphide may be prepared by heating a gel of highly dispersed cellulose with an equal weight of sulphur, preferably with addition of 1—5% of alkali or alkali carbonate, to 150° C. until evolution of hydrogen sulphide ceases, and a homogeneous mass is obtained. Cellulose sulphide is a yellow-grey to brown-grey mass, which evolves hydrogen sulphide on treatment with water. In the preparation of cellulose methyl ethers, 1 pt. of cellulose is dispersed in 8—15 pts. of water in a colloid mill, methyl alcohol (3 pts.) is added during the dispersion process, and etherification is effected by treatment with hydrogen chloride gas.—D. J. N.

Cellulose esters; Process for utilising [improving the dyeing properties of] ——. J. Duclaux. E.P. 184,197, 1.2.21.

Cellulose esters (other than the xanthate) are dissolved in volatile solvents, *e.g.*, formates or acetates of methyl, ethyl, butyl, amyl alcohol, etc., containing small quantities (1—5% on the weight of solvent) of organic substances such as acetamide and its homologues, chloral and chloral hydrate, which are non-volatile or but slightly volatile, are solvents for cellulose esters, and are soluble in water. Threads or films produced from these solutions by evaporation of the volatile solvent are washed with water to remove the non-volatile solvent. Non-granular, transparent products are obtained having dyeing properties closely resembling those of natural fibres. —D. J. N.

Cellulose derivative and process of preparing same. G. J. Esselen, jun., and H. S. Mork, Assrs. to A. D. Little, Inc. U.S.P. 1,425,580, 15.8.22. Appl., 10.4.20.

In the preparation of a cellulose butyrate soluble at normal temperatures in mixtures of benzol and alcohol, cellulose is subjected to a preliminary impregnating bath containing a solution of butyric acid and a catalyst.—H. H.

Cellulose ether solvent and composition. S. J. Carroll, Assr. to Eastman Kodak Co. U.S.P. 1,425,173, 8.8.22. Appl., 21.1.21.

An alkyl ether of cellulose is dissolved in a solvent containing 82—92 pts. of ethyl acetate, 7—12 pts. of ethyl alcohol, and 1—6 pts. of water by weight. —D. J. N.

Paper filler. W. Hoskins. U.S.P. 1,424,306, 1.8.22. Appl., 31.3.21.

Powdered calcium sulphate is superficially coated with an insoluble soap by washing it with soap solution. Other substances, which are slightly soluble in water, and are capable of forming an insoluble soap, may be similarly treated. The resulting products find application as fillers in the papermaking industry.—D. J. N.

Paper; Method for recovering [removing printer's ink from] waste ——. T. Jespersen, Assr. to Lincoln Trust Co. U.S.P. 1,424,411, 1.8.22. Appl., 15.12.16. Renewed 22.12.21.

Printer's ink containing a mineral oil vehicle is removed from waste paper by treating the paper stock with sodium silicate solution.—D. J. N.

Patterned textile fabrics; Process for producing —— and the resulting product. H. Giesler, Assr. to Heberlein u. Co., A.-G. U.S.P. 1,425,520, 15.8.22. Appl., 10.11.14.

See G.P. 282,351 of 1914; J., 1915, 713.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Assistants used in printing and finishing textile fabrics; The colloidal nature and influence of ——. N. J. Planowsky. Ber. Polyt. Iwanowo-Wosniessensk, 1921, **4**, 129—137. Chem. Zentr., 1922, **93**, IV., 551—552.

The pseudo or colloidal solutions of starch, dextrin, British gum, etc. such as are used for printing textile fabrics, are heterogeneous, homogeneous, or micellar according to their degree of dispersion, but this division is not always possible, since the states of these substances when in solution frequently change. Starch forms a precipitate with tannic acid, so that in printing pastes containing basic dyestuffs, colour lakes are formed which adhere only to the surface of the printed fabric and therefore are not fast. Analogous precipitates are formed with British gum and Gommelin, which are usually mixed with starch. Of the substances examined, starch had the most and Gommelin the least peptising power. In the presence of starch or gum tragacanth, dyestuffs partially diffuse into the textile fibres immediately after printing and this diffusion is hastened by steaming. In the presence of homogeneous substances, however, this diffusion is very small and is not assisted by steaming, so that the shade of the fabric is pale and not fast to washing. Fabrics printed with Malachite Green and starch or gum tragacanth appeared deeper than those for which Gommelin or British gum was used. Diffusion experiments showed that gum tragacanth has the greatest and British gum the least power of diffusion.—A. J. H.

Calico-printing; The possibility of using phosphorescent substances in ——. S. G. Schimansky. Ber. Polyt. Iwanowo-Wosniessensk, 1921, **4**, 171—172. Chem. Zentr., 1922, **93**, IV., 318—319.

Mixtures containing phosphorescent sulphides have been used successfully, the fabric being printed with a paste containing the sulphide, ammonia, and albumin. During printing, the fabrics must be protected from light, since the small quantities of acetic acid formed cause decomposition of the sulphides. Unsatisfactory results were obtained with acid dyestuffs, *e.g.*, Eosin and Fluorescein. —A. J. H.

Azo dyes of the naphthalene series. Woroshtzow. *See* IV.

Patents.

Colour printing; Double tone ——. Chem. Fabr. Worms A.-G. G.P. 354,081, 8.12.17. Addn. to 347,902 (J., 1922, 382 A).

A colour base is warmed with montanic acid and printers' ink added to the solution. The printing colour thus obtained is ready for use. The colour salts of montanic acid yield in printing a colour which stands out in more distinct contrast than that produced by the corresponding fatty acid salts. —J. B. F.

Vat preparations; Stable, dry, and readily-soluble —— *and process of making same.* K. Thiess, F. Maennchen, A. Steindorff, and F. Giloy, Assrs. to Farbwerke vorm. Meister, Lucius, u. Brüning. U.S.P. 1,426,522, 22.8.22. Appl., 23.8.21.

See E.P. 171,078 of 1921; J., 1922, 705 A.

Cellulose esters. E.P. 184,197. *See* V.

Bleach solutions. U.S.P. 1,426,752. *See* VII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid from gypsum. W. Dominik. Przemysl Chem., 1921, **5**, 185—191. Chem. Zentr., 1922, **93**, IV., 308.

Gypsum may be converted into ammonium sulphate and the latter into sodium hydrogen sulphate, from which free sulphuric acid may be obtained by (1) reduction of the free acid to sulphur dioxide and re-oxidation, (2) distillation with ballast (*cf.* Moscicki and Dominik, J., 1920, 746 A), (3) crystallisation of hydrated sodium sulphate by cooling and concentration of the mother liquor. Sodium sulphate increases in solubility with addition of free sulphuric acid to a maximum above which the acid sulphate separates. The solubility also decreases rapidly with the temperature; at $-11°$ C. the maximum solubility corresponding to 32% free acid is only about 4% Na_2SO_4 by weight, so that at this temperature a fairly complete separation can be obtained in one operation. A calculation of the water required and fuel consumption necessary for the decomposition of the acid salt at a given temperature is added.—C. I.

Calcium sulphate [and magnesium sulphate]; Reduction of —— *by carbon monoxide [carbon and hydrogen sulphide].* J. Zawadzki, K. Kossak, and H. Narbut. Przemysl Chem., 1921, **5**, 225—236. Chem. Zentr., 1922, **93**, III., 329.

At temperatures below 900° C., calcium sulphate is reduced to calcium sulphide; the reaction is quantitative about 900° C.; the velocity of reaction is sufficient for technical purposes. The calcium sulphide yields hydrogen sulphide quantitatively on heating with magnesium chloride solution. Above 900° C. calcium oxide and sulphur dioxide are also produced in quantities increasing with rise of temperature. Magnesium sulphate on reduction with carbon monoxide is almost completely converted into magnesium oxide, sulphur dioxide, and free sulphur. Magnesium sulphate reduced with hydrogen sulphide above 700° C. yields magnesium oxide whilst calcium sulphate under similar conditions is converted into calcium sulphide. The products of the reduction of calcium sulphate and magnesium sulphate by carbon are dependent on the temperature and the ratio of carbon to sulphate; at lower temperatures and with excess of carbon, magnesium sulphate leaves a residue containing magnesium sulphide as well as oxide; in the case of calcium sulphate the residue is sulphide only. At higher temperatures and with less carbon the products are magnesium oxide, sulphur dioxide, and sulphur, and calcium oxide and sulphur dioxide respectively.—J. B. F.

Hypochlorous acid; Ionisation constant of ——. *Evidence for amphoteric ionisation.* W. A. Noyes and T. A. Wilson. J. Amer. Chem. Soc., 1922, **44**, 1630—1637.

The ionisation constant k_a, representing $HClO \rightleftarrows H^{\cdot}+ClO'$ is $6{\cdot}70\times10^{-10}$ at 25° C. whilst the constant,

k_b, is too small to affect the conductivity of 0·0001*N* nitric acid when hypochlorous acid is added to it. When a current of air is passed through a solution of hypochlorous acid chlorine monoxide and not the acid is lost. This indicates the presence of positive chlorine ions and confirms the amphoteric ionisation, *i.e.*, in addition to ionisation represented by the above equation, ionisation also occurs according to the equation $HClO \rightleftarrows Cl^{\cdot} + OH'$.—J. F. S.

Causticising in the presence of silicate. R. H. McKee and T. H. Chilton. Pulp and Paper Mag., 1922, **20**, 693—694.

Experiments are described showing that it is possible to obtain satisfactory causticisation of soda solutions containing silicate by allowing sufficient time (longer than with carbonate alone) for the completion of the reaction.—H. R. D.

Potassium hydroxide; Application of Scheele's reaction to preparation of ——. W. Dominik. Przemysl Chem., 1922, **6**, 25—36. Chem. Zentr., 1922, **93**, III., 237.

The reaction,

$$2KCl+4PbO+H_2O \rightleftarrows PbCl_2+3PbO+2KOH$$

was studied, using mixtures containing not more than 20 g. of lead oxide per 100 c.c. of potassium chloride solution, filtering when the reaction was complete, adding a further quantity of lead oxide to the filtered liquid, and repeating these operations until equilibrium was attained. It was found that to obtain 1 g. of caustic potash about 16 g. of lead oxide is necessary. At the ordinary temperature the equilibrium between caustic potash and potassium chloride may be expressed by the equation:—

$$K = \frac{KOH}{KCl} = \frac{1}{0{\cdot}422 + 0{\cdot}074[OH]} - 1,$$

and the maximum concentration attainable is 112 g. KOH per litre. Regeneration of lead oxide by treatment of the lead chloride formed with milk of lime or calcium bicarbonate is not practicable, but may be accomplished by treatment with ammonium carbonate in presence of excess of carbon dioxide, whereby ammonium chloride and lead carbonate are formed, and the latter can be converted into lead oxide by treatment with steam at 300° C. With this method of regeneration the process as a whole becomes technically sound. —H. R. D.

Chlorates; Rôle of chromate in the electrolytic preparation of ——. A. W. Pamfilow. Ber. Polytech. Iwanowo-Wosniessensk, 1921, **4**, 113. Chem. Zentr., 1922, **93**, III., 327.

The addition of chromate in the electrolytic preparation of chlorate not only prevents the decomposition of hypochlorite and corrosion of the electrode, but also produces the required adjustment of acidity. If the solution is simply made acid or alkaline in the absence of chromate there is no variation in the concentration of the hydrogen and hydroxyl ions. To produce merely a protective film a trace of chromate would suffice, whereas in practice larger quantities are used. The phosphates have similar properties but are less suitable, since only sodium dihydrogen phosphate has an acid reaction and copper electrodes cannot be used. —J. B. F.

Ammonia; Presence of acetone in commercial ——. J. Bougault and R. Gros. J. Pharm. Chim., 1922, **26**, 170—171.

Examination of samples of ammonia from different sources indicates the presence of acetone in quantities varying from 0·01 to 0·5 g. per litre. This may be a source of serious error in analytical work, especially in the use of ammonia for physiological tests.—H. J. E.

Lime; Fundamental physical and chemical properties of commercial ——. I. The available lime content. M. L. Holmes and G. J. Fink. Chem. and Met. Eng., 1922, **27**, 347—349.

The loss on ignition and available lime, calculated on a non-volatile basis, of a large number of American samples are tabulated. By available lime is understood the total CaO, which is easily soluble in water, and it is determined as follows: 1·4 g. of the material, ground to pass 100-mesh, is boiled for 3 min. with 200 c.c. of water, and the solution is titrated with *N*/1 hydrochloric acid and phenolphthalein until the pink colour disappears for 1—2 seconds. The experiment is repeated in a 1 litre graduated flask using a quantity of acid (A c.c.) 5 c.c. less than before. Any lumps that form are ground up, and the solution is diluted to 1 litre with recently boiled distilled water. 200 c.c. is pipetted off and titrated with *N*/2 hydrochloric acid until the solution remains colourless with phenolphthalein for 1 min. If B c.c. be used in the second titration then the percentage of available lime is 2A+5B.—A. R. P.

Copper hydroxide; Solubility of —— in caustic soda solution. G. S. Melbye. Medd. Kgl. Vetenskapsakad. Nobelinst., 1921, **4**, [8], 1—11. Chem. Zentr., 1922, **93**, III., 480.

Copper sulphate solution is run into caustic soda solution until the solution becomes turbid. The precipitate is filtered off through glass wool, the filtrate diluted with water, and the copper estimated iodometrically with thiosulphate. The solubility of the copper hydroxide varies with the conditions and method of experiment, *e.g.*, the results vary with the size of the drops of the copper sulphate solution. The solubility is a linear function of the concentration between 2·65 and 6·6*N* caustic soda, and is expressed by the equation: $[Cu(OH)_2] = 0{\cdot}045[NaOH] - 0{\cdot}095$.—J. B. F.

Manganese dioxide; Some properties of ——. A. de Hemptinne. Bull. Acad. roy. Belg., Classe des Sci., 1922, **8**, 71—75. Chem. Zentr., 1922, **93**, III., 478—479.

Manganese dioxide is reduced by hydrogen or a mixture of hydrogen and hydrogen sulphide at ordinary temperatures, and at atmospheric pressure. After 5 days a rapid and progressive reduction in pressure due to absorption of hydrogen was perceptible (phosphoric anhydride was used to absorb the water formed), and after 53 days about one-third of the hydrogen had been used up. The reduced product was rapidly re-oxidised on exposure to the air. When manganese dioxide was exposed, similarly, to a mixture containing 33% of hydrogen sulphide and 67% of hydrogen a considerable diminution in volume took place in 3 mins., the manganese dioxide being converted into a sulphur compound, from which hydrogen sulphide was evolved on treatment with sulphuric acid.—J. B. F.

Sulphur dioxide; Oxidising and reducing properties of ——. I. Mercury chlorides. L. M. Stewart and W. Wardlaw. Trans. Chem. Soc., 1922, **121**, 1481—1489.

The type of reaction which occurs when sulphur dioxide reacts at 95° C. with mercurous chloride in the presence of hydrochloric acid depends on the concentration of the acid. With high concentrations of acid (8—2*N*) sulphur dioxide acts as an oxidising agent, sulphur being precipitated and mercuric chloride formed. At acid concentrations between 2*N* and 0·16*N* decomposition to mercuric chloride and mercury occurs to an extent decreasing with decrease in acid concentration. An inert period, extending over the range of acid concentration 0·16*N* to 0·07*N*, during which calomel is unaffected, is followed, below a concentration of

0·07*N*, by reduction of the chloride to mercury, increasing with decreasing acid concentration. With a definite concentration of acid the amount of reduction of mercuric chloride to the mercurous state by sulphur dioxide at 95° C. is dependent on the initial concentration of the mercuric chloride. Quantitative reduction occurs when sulphur dioxide reacts for 12 hours at 95° C. with 2·6 g. of mercuric chloride in 120 c.c. of water. Above this concentration of mercuric chloride the reduction is incomplete. For complete reduction of either chloride a very low acid concentration is necessary. Incomplete reduction occurs if the concentration of acid exceeds 0·02*N*. The small degree of ionisation of mercuric chloride in aqueous solution, and the fact that it forms complexes with hydrochloric acid, have an important bearing on the above reaction.—P. V. M.

Oxides of lead; Physical chemistry of ——. IV. Red lead and lead sesquioxide. S. Glasstone. Trans. Chem. Soc., 1922, **121**, 1456—1469.

Red lead and hydrated lead sesquioxide are plumbous salts, giving plumbous ions in solution. The hypochlorite and plumbite-plumbate methods for the preparation of lead sesquioxide are uncertain; in no case was an anhydrous sesquioxide obtained. Fairly pure hydrated lead sesquioxide can be obtained by a method based on the solubility of this oxide in alkali. A 12% solution of sodium hydroxide (250 c.c.) saturated with lead monoxide is diluted to 500 c.c., and an equal quantity of saturated bromine water added. The mixture, after standing overnight, and washing free from hypobromite and alkali by decantation with water plus a little acetic acid, is added, as an aqueous paste, to 60 g. of sodium hydroxide in 300 c.c. of water at 50° C. The cold filtrate from this mixture is treated, with continuous stirring, with 40 g. of acetic acid in 150 c.c. of water, and the precipitate washed and filtered with the aid of the pump. The ratio of lead dioxide to monoxide in the product is determined by analysis at this stage, and the solution in alkali and precipitation with acid repeated if necessary. The various methods of preparation of the sesquioxide are in harmony with the view that in a solution of the sesquioxide in alkali there is equilibrium between plumbate, plumbite, and hydroxyl ions. At ordinary temperatures the normal plumbate-plumbite potential is 0·30 volt. Consideration of the $Pb^{\cdot\cdot}$-ion concentrations produced by dissolving lead monoxide, sesquioxide, and dioxide respectively in *N*/1 caustic soda indicate that in the presence of lead dioxide and monoxide there will be a tendency for lead monoxide and sesquioxide respectively to dissolve in alkali to form red lead. In agreement with this lead sesquioxide was converted completely into red lead when left in contact with a solution of lead monoxide in alkali for six weeks.—P. V. M.

Oxides of lead; Physical chemistry of ——. V. Electromotive behaviour of lead dioxide. S. Glasstone. Trans. Chem. Soc., 1922, **121**, 1469—1480.

The system lead—lead dioxide—alkali is unstable; lead and lead dioxide combine directly in the presence of alkali to form red lead. The value of the $Pt/(PbO,PbO_2)N/1NaOH$ electrode potential is of the order of 0·27 volt. The high initial potential value of electrolytically deposited lead dioxide (from acid lead nitrate solution) is probably due to the presence of traces of a higher metastable acid oxide, possibly PbO_3, not capable of detection by analysis. The decomposition of this oxide is accelerated by rise of temperature and by plumbite solutions. The existence of hydrated lead dioxide is doubtful. The normal plumbic-plumbous potential has been redetermined, and a maximum value of 1·75 volts at 25° C. is indicated.—P. V. M.

Water vapour; Catalytic formation of —— from hydrogen and oxygen in the presence of copper and copper oxide. R. N. Pease and H. S. Taylor. J. Amer. Chem. Soc., 1922, **44**, 1637—1647. (*Cf.* J., 1922, 98 A.)

The combination of hydrogen and oxygen is practically complete at 200° C. when mixtures containing up to 5% of oxygen are passed over copper, prepared by reducing copper oxide in hydrogen at 150°—200° C., but is only just measurable at 100° C. In nearly all cases copper oxide is produced simultaneously with water. If the oxygen is shut off and pure hydrogen passed over the catalyst, the oxide so produced is reduced at a greater rate than that of the formation of water whilst the oxygen is passing. Between 130° C. and 100° C. the rate of oxidation of the copper and the rate of the reduction of the oxide so formed, as well as the catalytic activity, suffer a marked reduction. At 130° C. with a supply of oxygen equivalent to 10 mg. of water in 5 mins., the rate of formation of water passes through a maximum to a steady minimum value. (*Cf.* J.C.S., Oct.)—J. F. S.

Hydrogen peroxide; Colorimetric determination of ——. M. L. Isaacs. J. Amer. Chem. Soc., 1922, **44**, 1662—1663.

Hydrogen peroxide may be estimated colorimetrically as follows: 1 c.c. of a 10% solution of ammonium molybdate is slowly added to a mixture of about 30 c.c. of water, 10 c.c. of a 5% solution of citric acid, and 1 c.c. of the hydrogen peroxide, water is added to make the volume 50 c.c. and the whole well shaken. A yellow colour develops immediately and the solution is then compared with a standard potassium chromate solution (0·4 g. per litre) in a Dubosq colorimeter. When the standard is set at 20 the amount of hydrogen peroxide is given by $x=0{\cdot}05467/y$, where y is the colorimeter reading and x the number of grams of peroxide in the 50 c.c. of solution. The results obtained by this method compare favourably with those obtained by direct titration with potassium permanganate solution.—J. F. S.

Selenium oxychloride. V. Lenher. J. Amer. Chem. Soc., 1922, **44**, 1664—1667.

Selenium oxychloride is extremely hygroscopic and the greatest precautions are necessary to obtain the anhydrous material. The presence of small quantities of water increases the electrical conductivity enormously and its reactivity towards carbonates is largely dependent on the amount of water present. To test for the presence of water in selenium oxychloride cobalt carbonate which has been dried at 300° C. for 3 hrs. is sealed up with a sample of the oxychloride; in the absence of water no reaction occurs, but if the merest trace of water is present the oxychloride becomes blue and a pressure of carbon dioxide is set up. The dry carbonates of calcium, strontium, copper, nickel, and ferrous iron are without action on the oxychloride, whilst carbonates of barium, lithium, and magnesium evolve carbon dioxide slowly and that of zinc much more rapidly. Fused carbonates of sodium and potassium react readily with anhydrous selenium oxychloride evolving a large amount of heat. Sulphur dioxide has no action on the boiling anhydrous oxychloride, but in the presence of water selenium is precipitated. Dry hydrogen sulphide produces a red-brown colour, after which hydrogen chloride is evolved and yellow selenium sulphide is produced; heat is evolved and this dissociates the sulphide into sulphur and red selenium. Carbon monoxide has no action on the oxychloride. Chlorine is evolved by iodic acid, iodates, bromates, and persulphates. Tungsten, tantalum, and titanium are only slightly attacked after long periods at elevated temperatures. Phosphorus reacts violently at 0° C., producing selenium monochloride and tetrachloride and phosphorus pentoxide. Carbon tetrachloride dissolves selenium oxychloride but after a time phosgene is evolved and selenium tetrachloride formed.—J. F. S.

Selenium oxybromide. V. Lenher. J. Amer. Chem. Soc., 1922, **44**, 1668—1673.

SELENIUM oxybromide is best prepared by adding to pure resublimed selenium dioxide the calculated quantity of fused selenium in a flask fitted with a rubber stopper through which passes a dropping funnel and a safety tube filled with fused calcium bromide. The flask is cooled to 0° C. and the amount of bromine necessary to convert the metal into tetrabromide is cautiously added in small quantities. The mixture is then warmed until the whole of the oxide has dissolved. Selenium oxybromide is a reddish-yellow solid melting at 41·5°—41·7° C., boiling at 217° C. under 740 mm. with considerable decomposition. Owing to its decomposition on heating it cannot be purified by distillation even under reduced pressure. It has a density of 3·38 at 50°. Water converts it into selenious and hydrobromic acids. It dissolves in carbon bisulphide, chloroform, benzene, toluene, and xylene and the fused material is miscible in all proportions with these solvents. Carbon tetrachloride dissolves it readily but the fused material mixes only to the extent of 6%, and on heating for several days the solution evolves phosgene. It is an extremely active chemical reagent, behaving as a brominating and oxidising agent, and it is a powerful solvent. (*Cf.* J.C.S., Oct.)—J. F. S.

Iron oxides for gas purification. Gemmell. *See* IIA.

PATENTS.

Sulphuric and hydrochloric acids; Process of manufacture of ——. R. Stollé. G.P. 353,742, 14.6.14.

SULPHURIC and hydrochloric acids are prepared by the interaction of chlorine and sulphur dioxide in the presence of water at an elevated temperature.
—J. S. G. T.

Hydrochloric acid; Electrolytic method of manufacturing ——. T. Blasweiler. G.P. 355,387, 28.11.20.

SOLUTIONS of alkali chloride are electrolysed in cells in the anode chamber of which lignite or peat is suspended.—H. R. D.

Sulphurous acid; Process of producing —— *by heating sulphates.* M. Trautz. G.P. 356,414, 23.12.19.

SULPHATE, briquetted or mixed with charcoal or iron, is heated in the absence of hydrogen, in a stream of gas such as carbon dioxide, nitrogen, etc. which is not acted upon by sulphur dioxide, until all sulphur is expelled. Alternatively, the sulphate is initially heated in a stream of gases containing sulphur vapour and gases not acted upon by sulphur dioxide (carbon dioxide, sulphur dioxide, nitrogen, etc.) and then distilled in a stream of gas containing neither sulphur dioxide nor sulphur vapour.
—J. S. G. T.

Alkali lyes coloured and contaminated with hemicellulose; Process for purifying ——. F. Küttner Kunstseidespinnerei, and E. Profeld. G.P. 355,836, 22.2.21.

THE lye is treated in the cold with an oxidising agent such as hydrogen peroxide or ozone in the presence of metallic catalysts such as copper and lead. The oxidation may be carried out in vessels made of the metals which catalyse the reaction. The cellulose compounds in solution are precipitated on the surface of the metal and the solution is bleached. The purification is the more complete the greater the area of the metallic surface.—H. C. R.

Sodium carbonate, caustic soda and sulphur; Production of ——. Rhenania Verein Chem. Fabr. A.-G., and F. Projahn. G.P. 356,287, 16.2.16.

BARIUM sulphate is reduced to barium sulphide and then treated with water. The baryta is separated from the resulting liquor, which is treated with carbon dioxide to form barium carbonate and sulphur, the barium carbonate being afterwards treated with sodium sulphate, to form sodium carbonate and barium sulphate. The baryta is treated with sodium sulphate to form barium sulphate and sodium hydroxide, or it may be used to causticise the sodium carbonate previously obtained. The barium sulphate formed is again reduced to barium sulphide and the process repeated.—A. B. S.

Anhydrous chlorides of alkaline-earth metals; Process of manufacturing ——. Minami Manshu Tetsudo Kabushiki Kaishi. E.P. 163,304, 10.5.21. Conv., 15.5.20.

AN alkaline-earth carbonate, oxide, oxychloride, or hydroxide is heated with ammonium chloride in presence of a halide of a base electropositive to the alkaline-earth metal. For example, a mixture of 5 pts. of sodium chloride and 5 pts. of potassium chloride is maintained in a melted state at about 800° C., and a mixture of 30 pts. of ammonium chloride and 10 pts. of magnesium oxide is gradually added. The product consists of anhydrous magnesium chloride mixed with chlorides of sodium and potassium, and free from oxide; it is suitable for the electrolytic preparation of magnesium. The by-product ammonia and chlorine generated by electrolysis of anhydrous magnesium chloride are utilised to make the ammonium chloride for the process.
—H. R. D.

Barium chloride; Process for manufacture of pure —— *from barium carbonate and magnesium chloride lye.* Chem. Fabr. Coswig-Anhalt, and W. von Dietrich. G.P. 355,299, 3.11.20.

A FLUID mixture of barium carbonate and magnesium chloride lye is caused to set by addition of a dehydrating substance, *e.g.*, calcined barium chloride, and heated above the decomposition temperature of magnesium chloride. A portion of the calcined product may be used as dehydrating agent in the first stage of the process.—H. R. D.

Hyposulphites [hydrosulphites]; Process for the manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. E.P. 176,344, 20.2.22. Conv., 3.3.21.

HYDROSULPHITES of high concentration are obtained by treating a bisulphite solution with an amalgam, preferably of an alkali metal obtained electrolytically, and a free acid (hydrochloric, sulphuric, sulphurous), which is present in quantity equivalent to the non-mercurial metal of the amalgam. The bisulphite solution is well cooled and stirred, whilst adding the amalgam and acid. The mercury formed is returned to the electrolytic cell for use in the production of a further quantity of amalgam.
—H. R. D.

Soluble phosphates; Process of manufacturing ——. J. G. Williams. E.P. 184,206, 10.11.21.

A WATER-SOLUBLE sulphate, such as sodium, potassium, or ammonium sulphate, is caused to react with calcium phosphate in the presence of water and sulphur dioxide. When mineral calcium phosphate and ammonium sulphate are used the reaction gives calcium sulphate, diammonium hydrogen phosphate, and ammonium sulphite. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 26,097 of 1912.)—H. R. D.

Dibasic calcium phosphate; Process of reducing the amount of acid necessary in the manufacture of ——. Bayerische A.-G. für chem. u. landwirtschaftl.-chem. Fabrikate, and H. Hackl. G.P. 354,784, 20.8.20. Addn. to 352,782 (J., 1922, 723 A).

The interaction between monobasic calcium phosphate and finely ground bone meal in accordance with the previous patent is effected under the influence of heat and of the pressure set up by the carbon dioxide evolved.—J. S. G. T.

Potassium bicarbonate; Electrolytic production of —— *from potassium chloride solutions.* Chem. Fabr. Griesheim-Elektron, and R. Suchy. E.P. 184,244, 2.5.21.

A cathode solution containing, *e.g.*, 240 g. of potassium chloride and 140 g. of potassium bicarbonate per litre, is electrolysed until the potassium carbonate content reaches about 200 g. per litre. The liquor is transferred to a carbonating apparatus, about 20 g. of potassium chloride per litre added, and carbon dioxide introduced, until complete saturation results. The product is filtered off and the mother liquor, which has the same composition as the original cathode solution, is used again.—H. R. D.

Potassium and sodium carbonates; Preparation of a non-hygroscopic mixture of ——. A. Welter. G.P. 354,575, 21.4.21.

Sodium hydrogen carbonate and potassium hydroxide are allowed to interact in the solid state or in concentrated solution. A spray of concentrated caustic potash is blown into a reaction vessel containing finely powdered sodium hydrogen carbonate and the whole contents of the vessel are agitated with a current of air which removes excess moisture.—C. I.

Sodium silicate and the like; Furnace for producing ——. W. H. Stanton. U.S.P. 1,425,551, 15.8.22. Appl., 9.8.20.

The furnace is composed of a covered horizontal hearth, beneath which is a pair of gas regenerator chambers extending the full length. Beneath each of these chambers is an air regenerator chamber. A flue leading from the outer extremity of each regenerator space leads into the space between the superimposed hearth and roof at a point near an outer extremity of the hearth. Separate air or gas passages communicate with the inner end of each of the chambers for introducing the gas or air, and removing spent gases.—H. R. D.

Antimony trichloride; Preparation of aqueous solutions of ——. G. E. Williams, Assr. to Hooker Electrochemical Co. U.S.P. 1,425,565, 15.8.22. Appl., 10.8.20.

Metallic antimony is heated with chlorine in presence of hydrochloric acid sufficiently concentrated to prevent separation of oxychloride.
—H. R. D.

Purified gas mixtures; Process of preparing ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,425,577, 15.8.22. Appl., 8.5.20.

A mixture containing hydrogen, nitrogen, and carbon dioxide is passed in contact with ammonia free from contaminating impurities in order to prepare a mixture consisting essentially of hydrogen and nitrogen.—H. H.

Hydrogen and hydrogen-nitrogen mixtures; Process of generating ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,425,579, 15.8.22. Appl., 25.5.20.

A mixture of hydrocarbon vapour, steam, and air is passed into contact with iron-chromium surfaces at a high temperature.—H. H.

Zinc oxide; Method and means for producing ——. J. Thomson. U.S.P. (A) 1,425,917 and (B) 1,425,918, 15.8.22. Appl., 16.3. and 5.5.21.

(A) "Zinc gas," produced by re-distillation of metallic zinc in an electric furnace, is passed between impinging streams of "partially depotentiated" oxygen. (B) Crystalline zinc oxide is produced by oxidising superheated "zinc gas" by preheated air.—H. R. D.

Zinc oxide; Process of treating by-product ——. J. E. Booge, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,426,349, 22.8.22. Appl., 21.10.20.

The process consists in calcining by-product zinc oxide so as to form a product containing water-soluble compounds, which are removed by washing with water.—G. F. M.

Bleach [hypochlorite] solutions; Preparation of liquid ——. J. H. MacMahon, Assr. to The Mathieson Alkali Works, Inc. U.S.P. 1,426,752, 22.8.22. Appl., 4.3.22.

Liquid chlorine is vaporised by indirect contact with alkaline solutions, the heat of vaporisation of the chlorine being utilised to cool the alkaline solution, into which the gaseous chlorine is introduced.
—H. R. D.

Lead arsenate; Method of manufacturing ——. A. O. Allen, Assr. to J. Lucas and Co., Inc. U.S.P. 1,427,049, 22.8.22. Appl., 29.6.21.

Lead arsenate is precipitated from a basic solution of lead salts, obtained by mixing 70% acetic acid, 40° B. nitric acid, and litharge in the proportions by weight of 10:1:39 respectively by means of arsenic acid containing 58—63% As_2O_5.—H. R. D.

Potassium nitrate and ammonium sulphate; Process of manufacture of ——. Chem. Werke Lothringen, and T. W. Pfirrmann. G.P. 353,432, 4.1.21.

Potassium nitrate and ammonium sulphate or ammonium sulphate-nitrate are obtained by the double decomposition of potassium sulphate and ammonium nitrate in an acid solution preferably acidified with nitric acid.—J. S. G. T.

Nitrogen compounds, e.g., cyanides, cyanamides, nitrides, etc.; Process of producing —— *from metals, or metallic oxides or carbonates, and carbon and nitrogen.* Chem. Fabr. Griesheim-Elektron. G.P. (A) 305,612 and (B) 305,613, 14.3.14.

(A) The gases evolved in the process of manufacture are burned with so much air that essentially a mixture of nitrogen and carbon dioxide is produced, from which carbon dioxide is recovered as usual. (B) The reaction is carried out at a lower temperature, and is accelerated by the use of briquetted or powdered lignite or peat in place of coke or coal (anthracite).—J. S. G. T.

Ammonium salts; Process of manufacturing —— *from ammonia produced catalytically.* Badische Anilin u. Soda-Fabrik. G.P. 352,978, 24.4.21.

Ammonium salts, more especially ammonium sulphate and ammonium chloride, are produced by treating a solution or suspension of an appropriate salt (sulphate or chloride) with ammonia and subsequently or simultaneously with the mixture of carbon dioxide and hydrogen resulting from the catalytic interaction of water-gas and steam, the mixture of gases being if necessary freed from hydrogen sulphide. Carbonate formation is carried to completion by employing the carbon dioxide residue recovered from the gas by water under pressure and subsequent release of pressure.—J. S. G. T.

Ammonium salts containing tarry matter; Process of purifying ——. L. Singer. G.P. 353,744, 25.7.16.

A solution of the ammonium salt is treated with air, then slightly supersaturated with ammonia and filtered through sand or fuller's earth etc. Any residual tarry matter contained in the filtrate may, if necessary, be removed by treatment with steam. —J. S. G. T.

Sal-ammoniac waste; Process of working up ——. Metallbank u. Metallurgische Ges. A.-G., and W. Schopper. G.P. 353,636, 8.7.20. Addn. to 352,505.

The process described in the previous patent (*cf.* E.P. 145,085 of 1920; J., 1921, 734 A) is applied to the working up of other residues containing chlorides of heavy metals, and more especially to tin residues containing chloride. The material is mixed with an amount of dry slaked lime equivalent to its chlorine content, worked up with water to a crumbly mass, which is then treated with steam.—J. S. G. T.

Ammonium sulphate; Saturator for producing ——. Berlin-Anhaltische Maschinenbau-Akt.-Ges. G.P. 353,370, 17.10.20.

One or more sieves are inserted cross-wise in the gas distributor and acid is supplied from above. This arrangement produces a salt of exceptionally low acidity.—A. B. S.

Ammonium chloride; Production of ——. Holzverkohlungs-Industrie A.-G. G.P. 354,078, 10.10.17.

Ammonia and hydrochloric acid, both in gaseous form, and the latter in slight excess, are passed through methyl alcohol or other liquid in which both the gases are soluble, but ammonium chloride is insoluble. Pure ammonium chloride is thus obtained direct without evaporation.—A. B. S.

Hydrocyanic acid; Process of increasing the stability of ——. Deutsche Gold- u. Silberscheideanstalt vorm. Roessler. G.P. 352,979, 5.4.19.

The stability of hydrocyanic acid is increased by the addition of a little oxalic acid.—J. S. G. T.

Extraction process; Continuous ——, particularly for separating potassium chloride from crude potassium salts. Fellner und Ziegler, and M. König. G.P. 355,979, 25.7.19.

The solvent liquor at a low temperature is brought into contact with the salts in an extractor consisting of two chambers one above the other and connected so as to allow the salt to be separated from the liquor. Between these chambers is a preheating and settling chamber for treating the solvent liquor after it has been run off the salt.—A. B. S.

Sodium bisulphate; Separation of —— in the solid state from solutions. Spinnstoff-fabrik Zehlendorf G.m.b.H., and K. Leuchs. G.P. 356,103, 3.2.20.

The solution is treated with concentrated sulphuric acid.—A. B. S.

Aluminium sulphate; Process for preparing —— from aluminium hydroxide. Vereinigte Aluminiumwerke A.-G., and W. Fulda. G.P. 354,328, 15.3.21.

Aluminium hydroxide is heated with ammonium sulphate and the ammonia evolved re-converted into sulphate by means of gypsum.—C. I.

Aluminium oxide; Process for production of —— from bauxite. Schweizerische Sodafabrik. G.P. 355,301, 25.6.21.

Bauxite is emulsified with soda lye, without the use of pressure, in a homogenising apparatus provided with at least one turbine wheel.—H. R. D.

Aluminium oxide: Manufacture of —— from materials containing alumina and silica. Metallbank und Metallurgische Ges A.-G. G.P. 355,302, 12.5.16.

Furnace slags, especially blast-furnace slag, rich in alumina, either alone, or mixed with other substances rich in alumina, are treated by a process whereby soluble sodium aluminate and insoluble calcium silicate are formed.—H. R. D.

Aluminium compounds; Process for separation of —— from other substances, especially iron compounds. Rhenania Ver. Chem. Fab. A.-G. Zweigniederlassung Mannheim. G.P. 355,303, 24.9.18.

A solution (not too dilute) of the substances under treatment is mixed with a sodium salt and an alkali fluoride, avoiding excess of the latter, and the double fluoride which separates is washed with water or very dilute acid till free from foreign matter.—H. R. D.

Silver halides; Process for preparing solid, colloidally soluble ——. J. D. Riedel A.-G. G.P. 354,450, 14.5.19. Addn. to 350,097 (J., 1922, 392 A).

A colloidally soluble silver halide preparation is obtained by addition of water to the colloid solution prepared as in the chief patent.—C. I.

Magnesium chloride lyes; Treatment of ——. W. Esch. G.P. 355,300, 22.1.20. Addn. to 332,153 (J., 1921, 302 A).

About eight-ninths of the magnesium is separated as basic carbonate by treating the lye with magnesium hydroxide and secondary ammonium carbonate or its components (ammonia and carbon dioxide) in corresponding proportions. The mother liquor instead of being treated with lime, as in the chief patent, is boiled with excess of magnesium oxide or hydroxide, the liberated ammonia being recovered and used again in the process. The residue, consisting of magnesium chloride, together with the excess of magnesium oxide or hydroxide, is then heated to a higher temperature to obtain hydrochloric acid, and the residue from this operation, which consists chiefly of magnesia, is used again in the process, after being leached, if necessary, to recover potassium salts.—H. R. D.

Minerals or oxides; Process for decomposing or dissolving refractory ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 355,738, 12.7.19.

Refractory minerals or oxides may be dissolved after treatment with a mixture of alkali oxide and hydroxide.—A. R. P.

Hydrogen peroxide; Process for producing ——. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. G.P. 355,866, 1.9.16.

Concentrated sulphuric acid is allowed to flow into a suspension of alkali perborate in water, the quantities of acid and perborate being so adjusted that a solution of hydrogen peroxide is obtained, having a concentration preferably of 20%, but in any case more than 10%.—A. R. P.

Metallic salts; Production of —— from ores, slags, residues, etc. J. Leibu. G.P. 356,293, 13.4.20.

Metals or metallic oxides in the form of vapour, or waste gases containing them, with either oxidising or reducing gas as may be required, are brought into contact with acids and the resulting salts are recovered by customary methods.—A. B. S.

Mercury; Electrolytic oxidation of —— in sodium carbonate solution. Consortium für Elektrochem. Ind., G.m.b.H. G.P. 356,507, 3.5.18.

The sodium carbonate solution should not contain less than 0·02% or more than 0·08% of halogen salts, preferably sodium chloride. The process is particularly applicable to re-oxidising the metallic mercury produced in the preparation of acetaldehyde from acetylene, so as to obtain a fresh supply of mercuric oxide used in this process.—A. B. S.

Iodine; Process for recovering ——. O. V. Faber. E.P. 168,324, 23.8.21. Conv., 28.8.20.

Carbon or carbonaceous material containing absorbed iodine (*e.g.*, from mineral water) is heated in presence of a medium (*e.g.*, a current of air or carbon dioxide) which will carry away the iodine as evolved.—H. R. D.

Inert gases, e.g., nitrogen and argon; Process of producing —— free from oxygen and hydrogen. Patent-Treuhand Ges. für elektrische Glühlampen m.b.H. G.P. 353,743, 9.4.20.

The inert gas is freed from oxygen by heating with an excess of hydrogen, which is subsequently removed from the perfectly dried gas by liquefaction. The last traces of hydrogen are removed from the liquefied mixture of gases by boiling.—J. S. G. T.

Gas [nitrogen and oxygen] mixtures; Process for separating ——. R. and R. Mewes. G.P. 354,217, 12.3.19.

The vapours of low oxygen content passing away from the oxygen condensing column are forced by means of a jet, along with cooled and purified air, into the nitrogen column, passing through the liquid flowing from it.—C. I.

Sulphur; Process of obtaining —— in a finely powdered form. F. Meyer. G.P. 356,047, 24.6.21.

Sulphur vapour is passed over or through liquids such as alcohol, acetone, benzene, carbon bisulphide, trichloroethylene, or mixtures thereof, which have the property of abstracting the finely divided sulphur present in the vapour without causing it to agglomerate. On removal of the liquid the sulphur is obtained in a finely divided form.—A. R. P.

Sulphuric acid chambers; Construction of ——. R. E. Dior. U.S.P. 1,426,261, 15.8.22. Appl., 25.3.21.

See E.P. 164,572 of 1920; J., 1921, 582 A.

Oxides of nitrogen; Process for the production of —— from ammonia by catalytic oxidation. C. Bosch, Assr. to Badische Anilin u. Soda Fabrik. U.S.P. 1,426,952, 22.8.22. Appl., 9.7.20.

See E.P. 145,059 of 1920; J., 1921, 811 A.

Metal oxides; Process for obtaining volatilisable ——. F. D. S. Robertson. U.S.P. 1,426,602, 22.8.22. Appl., 16.12.18.

See E.P. 147,470 of 1920; J., 1922, 99 A.

Hydrogen; Production of ——. G. Claude, Assr. to L'Air Liquide Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. U.S.P. 1,426,462, 22.8.22. Appl., 31.5.18.

See E.P. 131,091 of 1918; J., 1918, 765 A.

See also pages (A) 736, *Absorption tower for hydrochloric acid* (G.P. 383,553); *Drying substances containing free alkali* (G.P. 352,343). 737, *Catalyst* (U.S.P. 1,425,576). 738, *Acid-resisting linings* (G.P. 355,874). 740, *Sulphur from gas scrubbers* (G.P. 355,867). 741, *Aluminium chloride* (U.S.P. 1,426,081). 771, *Oxide of iron* (E.P. 183,323).

VIII.—GLASS; CERAMICS.

Gilding glazed clay vessels. P. P. Budnikow. Ber. Polyt. Iwanowo-Wosniessensk, 1922, **6**, 211—220. Chem. Zentr., 1922, **93**, IV., 235.

The author has examined various methods of gilding glazed clay ware. A suitable gilding solution is produced by precipitating gold from solution in *aqua regia* by hydrous ferrous sulphate. The precipitate is ground with 8—10% of a flux consisting of 6 pts. of basic bismuth nitrate and 0·5 pt. of anhydrous borax, mixed with oxidised turpentine and lavender oil, and applied to the wares. A bright gold film is produced after baking at 650°—900° C. Paler hues are obtained if about 30% by weight of silver chloride is mixed with the gold. "Sulphur balsam" may likewise be employed for gilding. 100 g. of dry French turpentine is mixed with 20 g. of sulphur and 20 g. of Venetian turpentine and boiled gently on an oil bath. Acids must be distilled off at intervals, and it is best to carry out the distillation in a stream of carbon dioxide, employing a long glass tube as a reflux condenser. To 8—9 pts. of the balsam so prepared, a solution of gold chloride containing 1 pt. of gold, 4 pts. of concentrated hydrochloric acid, and 4 pts. of nitric acid, diluted with water, is added, and the mixture heated on an oil bath until the gold dissolves. Water is removed, and 7—8% of lavender oil and 12% of French turpentine added, and the mixture heated until completely mixed. The resulting mass is dissolved in carbon bisulphide and filtered. The carbon bisulphide is evaporated off, and 5—8% of basic bismuth nitrate added, and the resulting mass applied to the wares, which are then carefully baked at 450°—600° C. The reactions occurring have been investigated by studying the interaction of sulphur and pinene. $C_{10}H_{16}S$ or $C_{10}H_{16}S_2$ is probably formed by reaction between pinene and sulphur. With gold chloride, the compound $C_{10}H_{16}S,AuCl_3$ is probably formed, and by baking, this is probably decomposed into $C_{10}H_{16}Cl_2$, Au and SCl_2. Gold sulphide gives only a matt film, under the conditions of the experiments. "Sulphur balsam" may be prepared by the interaction, at room temperature, of sulphur monochloride and turpentine, the evolution of hydrogen sulphide and hydrogen chloride being prevented by cooling. Used in conjunction with gold chloride this gives even better films than the first-mentioned balsam.
—J. S. G. T.

Quartz; Heat of crystallisation of ——. R. C. Ray. Proc. Roy. Soc., 1922, **A 101**, 509—516.

The heat of crystallisation of quartz has been determined from the respective values of the heat of solution in hydrofluoric acid of silver sand and silica glass, which were found to be 30·29 and 37·24 kg.-cals. per g.-mol. of silicon dioxide respectively, the difference, 6·95 kg.-cals. per g.-mol., representing the heat of crystallisation of quartz. The value is considerably higher than the values obtained by Wietzel (2·32) and by Mulert (2·21), and the discrepancy is attributed to the effect of prolonged grinding in reducing part of the substance to the vitreous condition. The calculated value of the heat of crystallisation at 900° C. is 6·50 kg.-cals. per g.-mol. At the melting point, the value is very nearly the same as that at air temperature. (*Cf.* J.C.S., Oct.)—J. S. G. T.

Patents.

Alkali metal silicates [for glass-making]; Process of producing —— in blast furnaces. S. Peacock, Assr. to C. W. Waggoner. U.S.P. 1,425,048, 8.8.22. Appl., 18.12.20.

A mixture of carbon, silica, and a colourless non-oxidising alkali metal compound is smelted in a blast furnace and the slag is tapped and utilised for glass-making purposes.—A. R. P.

Muffle-flattening oven and leer. E. E. Milner and W. J. Lytle, Assrs. to H. L. Dixon Co. U.S.P. 1,426,309, 15.8.22. Appl., 12.8.21.

A flattening oven comprises a chamber containing a flattening stone, a number of heating flues in the top walls of the chamber, an off-take at one end of each of the flues, another off-take between the ends of the flues, and means for regulating the flow of gases in the off-takes.—A. B. S.

Annealing lehr; Plate-glass ——. E. E. Milner and W. J. Lytle, Assrs. to H. L. Dixon Co. U.S.P. 1,426,310, 15.8.22. Appl., 16.8.21.

An annealing lehr for plate-glass comprises several muffle heating chambers arranged zigzag, a number of heating flues in the top wall of each chamber, with off-takes in each flue, means for producing combustion in these flues, and connecting flues common to all the chambers and to all the off-takes.—A. B. S.

Lamp-bulbs and other glass ware; Melting together of glass parts of —— by means of soluble fluxes. L. S. Vello. G.P. 355,883, 4.5.19. Conv., 22.1.19.

A flux composed of phosphoric acid and lime has the advantage of being more readily fusible and more free from colour than the lead fluxes generally used, and of having a coefficient of expansion similar to that of the glasses used for the purposes named.—A. B. S.

Silica; Production of dense, acid-resisting articles from ——. O. Bühring. G.P. (A) 353,912, 31.5.19, (B) 353,913, 27.5.22.

(A) Silica sand is mixed with plaster and moulded; the resulting articles are saturated with a solution of water-glass, fired, and then soaked in sulphuric acid or other acid. They are again treated with water-glass and afterwards with acid and again fired, these processes being repeated as often as is desired. (B) The firing of articles made as described is continued until the mass is vitrified.—A. B. S.

Mica sheets; Process of manufacturing refractory —— from mica waste. P. Kertész. G.P. 349,849, 6.11.20.

Mica waste is finely ground and worked up with silicic acid, with just sufficient alkali and lime to enable the silica to set. The mixture is formed into sheets and heated until the silicate melts. Alternatively an alkali silicate may be employed as binding medium and silicic acid added until no free alkali is present. The product is suitable for insulating heated conductors, *e.g.*, resistance wires, or for fixing them to supports.—J. S. G. T.

China clay or like clays; Treatment of ——. T. Rigby. E.P. 183,535, 16.4.21.

China clay or like clay suspended in water, is concentrated by settlement or by mechanical means, such as a rotary filter, until it contains only about 50% of water. The product is dried in a continuous manner, by spreading it as a film on a surface heated by steam, in an evaporating plant of the type specified in E.P. 180,963, 181,035, or 149,055 (J., 1920, 682 A; 1922, 573 A, 574 A), or in any other suitable plant, using steam at low pressure as the drying agent. The use of various known types of excavators in association with the evaporating plant is claimed.—A. B. S.

Clay; Treatment of ——. W. Feldenheimer and W. W. Plowman. E.P. 184,271, 9.5.21.

Clay is purified by suspending it in water, adding a solution containing 1—3 lb. of metaphosphoric acid (or the equivalent amount of sodium metaphosphate, or a mixture of sodium carbonate and metaphosphoric acid) to each ton of clay, allowing the coarser particles to settle, running off the supernatant liquid, and flocculating the clay therein by the addition of a solution of alum. (*Cf.* E.P. 121,191; J., 1919, 41 A.)—A. B. S.

Kaolin; Process of producing ——. R. Froelich. G.P. 350,918, 22.10.20.

Native felspathic kaolin rock, free from iron, lime, magnesia, and mica, is decomposed into clay, quartz, felspar, and other products by drying, disintegration, mechanical working, and winnowing.—J. S. G. T.

Tunnel ovens or kilns for firing pottery, tiles, and the like. C. F. Bailey. E.P. 183,708, 23.7.21.

A tunnel oven may be built shorter than usual if its ends are at a lower level than the middle where the heating zone is situated. The trucks are moved by means of an endless chain fitted with arms which connect it to the cars. The chain and arms may run in an air-cooled groove.—A. B. S.

[*Tunnel*] *kiln.* R. T. Kyle. U.S.P. 1,426,655, 22.8.22. Appl., 10.3.21.

A tunnel kiln has a series of heat inlets at horizontally spaced points along one vertical side and a single heat outlet at the opposite side to the heat inlets and in the same horizontal plane, so that the heat is forced to travel diagonally across the tunnel and through the ware before passing to the outlet. —A. B. S.

Tunnel-kiln for baking ceramic articles etc.; Gas-fired ——. A. Dahl. G.P. 350,143, 10.7.20.

Air for combustion is preheated in separately controlled channels in the roof of the kiln, and flows from these into a longitudinal channel arranged in the combustion arch of the kiln, whence the stream branches on both sides of the kiln walls and passes to common channels, arranged below the kiln on either side and communicating with the channel for supplying gas to the combustion chamber. The nostrils of the latter channel are situated behind the combustion arch and are longer and narrower in the front part of the kiln used for the preliminary slow firing than in that part in which the goods are subjected to a full heat.—J. S. G. T.

Kiln; Method for heating a periodic —— by producer gas. F. and K. Meiser. G.P. 352,224, 17.4.21.

Air is drawn in by the action of the producer gas, which is introduced under pressure, and is heated in the first place either by the flue gases or by passing through channels heated by the furnace wall and secondly in channels surrounding the producer shaft. The suction action produced by the inflowing gas under pressure allows much more gas to burn in a narrow space, and a stable flame and high temperature are quickly attained.—J. B. F.

Sagger furnace; Annular —— in which the saggers can be manipulated from above. F. and K. Meiser. G.P. 354,948, 5.12.20.

A burner is arranged at one external end and the chimney at the other end of heating passages built between the saggers, so that the direction of flow of the hot gases is reversed in the furnace. The furnace can be emptied from below, and hoods are provided for collecting gases and vapours. The furnace is suitable for baking electrodes, clay ware, etc.—J. S. G. T.

Enamel coating to metallic surfaces; Method of producing and applying ——. H. M Smith, Assr. to Stanley Insulating Co. U.S.P. 1,425,612, 15.8.22. Appl., 30.9.18.

The enamel mixture is distributed over the surface and an air blast applied during the fusion process. —D. F. T.

Ceramic products; Process of manufacturing porous ——. Soc. Anon. le Carbone. G.P. 351,790, 29.2.20.

A powdered mixture of clay, gypsum, and wood charcoal is mixed with water to a paste which is then moulded as desired and baked. Alternatively, a mixture of clay, grog, and calcium carbonate (powdered chalk or marble) is baked.—J. S. G. T.

Porcelain and the like; Firing ——. Siemens-Schuckertwerke G.m.b.H. G.P. 353,857, 27.5.22.

In a gas-fired kiln, the flames are made to resemble those from coal by the addition of other combustible matter. Very smoky flames are produced by means of turpentine, resin, etc. which are burned in a special furnace and then introduced into the gas flames, or the smoke-producing material may be introduced directly into the gas flames.—A. B. S.

Fluxes in ceramic masses; Process for thoroughly distributing ——. L. Wessel Akt.-Ges. für Porzellan u. Steingutfabr. G.P. 354,941, 17.6.22.

The flux is added to the ceramic mass in the form of a solution of a soluble salt and, after being thoroughly mixed, is precipitated by the addition of a suitable reagent.—A. B. S.

Carbon and articles containing carbon; Process for coating —— *with enamel, quartz, or glass.* N. Meurer. G.P. 355,467, 23.8.21.

The articles are first given a thin coating of copper, nickel, iron, silver, or the like by the spraying process and then a coating of enamel is applied by any suitable process. By this means any desired portion of a carbon article may be electrically insulated. —A. R. P.

Graphite; Manufacture of shaped pieces of pure ——. E. Trutzer. G.P. 355,484, 23.11.20.

Finely powdered graphite is intimately mixed with a colloidal solution of graphite, the mixture is moulded into the desired shape, and the dispersion medium removed by spontaneous evaporation, by heat, or by high pressure, or by a combination of these methods.—H. R. D.

IX.—BUILDING MATERIALS.

Concrete; Flexural strength of plain ——. D. A. Abrams. Amer. Conc. Inst., 1922, 18. Lewis Inst. Structural Materials Research Laboratory, Bull. 11.

Tests of the flexural strength (modulus of rupture) of 750 plain concrete beams (38 in. by 10 in. by 8 in.) were made by applying loads at the ⅓ points of a 36 in. span, a wide range of mixtures, consistencies, size and grading of aggregate and curing conditions being employed. It was found that there is no uniform relation between the modulus of rupture and the compressive strength, though for the usual concrete mixtures the modulus of rupture is about 22% of the compressive strength. An increase either in the proportion of cement or in the size of the aggregate increased both the flexural and compressive strengths of the concrete. An increase in the proportion of water reduced both the flexural and compressive strengths. The advantage of curing in a damp state was fully shown by the tests. Both the flexural and the compressive strengths after curing in a damp state were proportional to the logarithm of the age of the concrete. No serious discrepancy between the flexural and compressive strengths was caused by using pebbles, crushed slag, or crushed limestone as aggregate, but granite gave slightly lower values possibly because of its low absorption. There is a definite relation between the water-ratio (*i.e.*, volume of water to volume of cement in the batch) and the flexural strength, just as there is between the water-ratio and the compressive strength, but the curve representing the former is of an entirely different form from that representing the latter; with an increase in the water-ratio the compressive strength drops rapidly at first and then more slowly, whilst the flexural strength drops slowly at first and then rapidly. In most of the tests a variation in any one constituent or condition had a much smaller effect on the flexural than on the compressive strength, but on the whole the relations between the two strengths are consistent.—A. B. S.

Plaster; Setting and velocity of solution of ——. P. P. Budnikow and J. K. Syrkin. Ber. Polyt. Iwanowo-Wosniessensk, 1922, 6, 235—248. Chem. Zentr., 1922, 93, III., 476—477.

The velocity of solution of plaster prepared by calcining gypsum at various temperatures was determined by electrical conductivity measurements. Plaster prepared by calcining at 115°—125° C. dissolved rapidly at first and then more slowly; after 24 hrs. the solution was feebly supersaturated relative to $CaSO_4,2H_2O$. The results were similar for plaster prepared at temperatures up to 400° C. The solubility-temperature curve is regular. Plaster prepared at 500° C. and higher (up to 800° C.) forms no supersaturated solution; the amount passing rapidly into solution is very small. Within this range lies the formation of so-called dead-burnt plaster. Dead-burnt plaster even when produced at 800° C., contains a proportion of soluble anhydrite which passes into solution but is mechanically prevented from setting by the insoluble anhydrite, which prevents coalescence of the soluble crystalline modification. The addition of easily crystallisable substances, such as alum, accelerates the setting. The setting of the soluble component is invariably followed by a slow conversion of the insoluble anhydrite into the soluble modification. This also takes place, though slowly, even after prolonged calcining at 800° C.—J. B. F.

Patents.

Wood; Process of treating ——. H. F. Ammon. E.P. 165,784, 9.6.21. Conv., 1.7.20.

Wood, especially for the manufacture of pencils, is rendered more durable and easier to work, by being submitted to the action of air heated to 420°—480° C. until it has acquired a uniform brown colour without appreciable decomposition.—D. F. T.

Wood-preserving agent. Grubenholzimprägnierung G.m.b.H. G.P. 356,132, 14.12.21.

The agent contains soluble fluorine and arsenic compounds. For instance, arsenious oxide and sodium fluoride are dissolved in water, the solution is diluted and employed in the usual manner for impregnating wood, with or without the addition of other antiseptic salts, or salts reducing the combustibility of wood. The protective effect against fungi of arsenic and fluorine compounds used in conjunction is greater than the additive effects of the constituents.—H. C. R.

Cements; Production of aluminate ——. W. Mathesius. G.P. 307,169, 28.2.18.

Suitable mixtures of bauxite or bauxite residues and lime are heated to fusion under reducing conditions so as to separate the metallic iron produced, or they may be fused under oxidising conditions. The resulting slags should have one of the following percentage compositions:—(1) Al_2O_3 20, SiO_2 13, CaO 67%; (2) Al_2O_3 20, SiO_2 24, CaO 56%; (3) Al_2O_3 76, CaO 24%; (4) Al_2O_3 42, CaO 58%.—A. B. S.

Building material; Process of manufacturing ——. A. Savelsberg. G.P. 350,363, 23.5.20.

Combustible refuse and inferior fuels in general, are calcined together with binding media, *e.g.*, limestone, dolomite, gypsum, etc., in a converter supplied with a blast. The combustible materials serve to reduce the plasticity of the mass and supply the heat necessary for the calcining process. —J. S. G. T.

Building materials; Treatment of —— *made of unfired loam, water-glass, and sulphite waste.* Silonit Baugesellschaft m.b.H. G.P. 351,677, 16.7.20.

The exposed faces of blocks of artificial stone are coated with a mixture of magnesia and aluminium "fluate" so as to render them waterproof. —A. B. S.

Cement and concrete materials; Process of manufacturing ——. O. Roucka. G.P. 352,175, 18.6.21.

The raw materials are heated in a closed vessel in which the temperature rises at the rate of 1°—1·5° C. per minute until a temperature of 60°—80° C. is attained. Thereupon, by heating the vessel from beneath and simultaneously regulating the admission of steam, the pressure in the vessel is raised to about 8 atmospheres, to which the materials are subjected for about 8—10 hours. The crushing strength of cement manufactured in this way exceeds 600 kg. per sq. cm.—J. S. G. T.

[*Hydraulic*] *powder; Production of a rapidly hardening* —— *from cement and alkali carbonate.* B. Hövermann. G.P. 353,617, 7.4.21.

A mixture of 100 pts. of cement, 2—4·5 pts. of alkali carbonate, and 1—1·5 pts. of aluminium sulphate yields a product which is impermeable to water under either low or high pressure.—A. B. S.

Weather-proof stone; Production of ——. B. Riedel. G.P. 353,618, 17.11.20.

A dry mixture of granite, serpentine, and cement is sprayed with a solution of caustic soda; the product is thoroughly mixed and made into blocks of the desired shapes. The resulting stones are very durable and impermeable.—A. B. S.

Building materials; Production of unfired ——. Dr. Plönnis und Co. G.P. 354,069, 20.10.19. Addn. to G.P. 342,403 (J., 1922, 103 A).

Loam or clay and waste sulphite liquor are mixed with porous materials such as peat, turf, sea-wrack, leaves, pine needles, or fibrous material.—A. B. S.

Refractory concrete; Process for the manufacture of ——. C. Loeser. G.P. 355,372, 16.9.16.

The refractory consists of a mixture of cement and particles of grog coated with corundum or similar material.—A. R. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast iron and its chemical composition. O. Smalley. Brit. Foundrymen's Assoc., 1922. Engineering, 1922, 114, 277—281.

The remelting of chilled cast iron yields close-grained tough castings, and by the addition of 10—15% of mild steel, the grain may be refined still further. Dirty castings and blowholes cannot be attributed directly to the presence of oxygen, as even the cheapest grade of metal, whether melted with or without steel, will give a clean casting if correctly melted and poured at the proper temperature. The effect of deoxidisers, *e.g.*, cerium, uranium, calcium, vanadium, aluminium, magnesium, manganese, and zirconium, was tried on a working scale, and no benefit was obtained by using up to 0·2% of the alloying element, a quantity which should be sufficient to counteract the effect of incorrectly melted iron. Generally the degree of superheat in iron melted in cupolas may be taken as corresponding to 10% above the melting point of the particular mixture used, but other considerations of casting practice suggest that this should not be an arbitrary figure. Solidity of the casting should be controlled by the aid of the chemical composition, casting temperature, and the rate of solidification, as it is a direct function of the quantity and form of the graphite separated. The limitations of cast iron for use in internal combustion engine parts, or other plant working at high temperatures, are shown by experiments in which the tensile strength fell at 200°—500° F. (94°—260° C.), rose to a maximum between 800° and 900° F. (427°—482° C.), and then rapidly fell to less than 2·5 tons per sq. in. at 1530° F. (832° C.).—C. A. K.

Cast-iron; Occurrence of ferrite-graphite eutectic in certain kinds of ——. E. Schüz. Stahl u. Eisen, 1922, 42, 1135—1136.

A cast iron of the following composition: graphite 3·22%, combined carbon 0·38%, Si 3·31%, Mn 0·88%, P 0·89%, and S 0·104%, showed a large amount of graphite-ferrite eutectic surrounding well-defined ferrite polygons and pearlite crystals, while free graphite flakes were evenly distributed throughout the mass. The iron had a Brinell hardness number of 150 and good mechanical properties, and could be readily machined. The structure was probably produced in the following manner: on cooling from 1240° to 1152° C. mixed crystals are precipitated which become slowly enriched in carbon, viz., from 0·8 to 1·3%. At 1152° C. the ferrite-graphite eutectic with 4·5% C freezes out, while at the same time in the regions of pure pearlite the mass cools according to the metastable Fe—Fe_3C system in which between 1240° and 1145° C. mixed crystals with 0·8—1·7% C separate, followed by freezing of ledeburite at 1145° C. Eventually the latter decomposes between 1145° and 1090° C. into free graphite and pearlite.—A. R. P.

[*Steel.*] *Diminution of lag at Ar*1 *through deformation.* J. H. Whiteley. Iron and Steel Inst., Sept., 1922. [Advance proof.] 5 pages.

Pieces of mild steel plate which had been allowed to cool in the centre of a solidifying slag ball were heated to 900° C., allowed to cool to 695° C. in 10 mins., and after 15 mins. at this temperature, hammered to produce a comparatively small deformation, then quenched in water. Micro-examination showed that the pearlite transformation was nearly complete, while this transformation was found to take place very slowly in undisturbed specimens. In strips similarly heat treated but bent through 60° with light hammer blows pearlite was present at the bends, but where the metal had not been distorted the structure consisted of ferrite and martensite only. A similar but less pronounced effect was found at 700° C. Strips were also heated to 900° C., cooled a little below Ac3, and then bent, but the separation of free ferrite from solid solution was not accelerated.—T. H. Bu.

Iron and steel; Crystal structure of ——. A. Westgren and G. Phragmén. Z. physik. Chem., 1922, 102, 1—25.

Röntgen photographs of iron wire at 800°, 1100°, and 1425° C., show that iron within the so-called β- and δ-regions has a space-centred cubic lattice similar to that of α-iron, whilst iron in the γ-iron region has a face-centred cubic lattice. The transition which occurs at 900° C. (A3) is therefore reversed at 1400° C. (A4). The γ-iron lattice of austenitic steel is extended by the dissolved carbon. A steel containing 1·98% of carbon possesses a larger iron lattice when it is quenched at 1100° C. than when quenched at 1000° C., also the α-iron lattice in martensite appears to be somewhat extended by the carbon. The homogeneous lattice region within the α-iron range in martensite is extremely small. A steel containing 0·80% of carbon quenched at 760° C. is practically amorphous. Röntgen photographs of cementite and spiegeleisen are identical. Cementite crystals belong to the rhombic system and have an axial ratio 0·670:0·755:1. The elementary parallelepiped has dimensions 4·53, 5·11 and 6·77 AU and contains 4 molecules of Fe_3C, consequently the specific gravity of cementite is 7·62.—J. F. S.

Steel; Rapid determination of the elongation and resistance to shock of ——, by bending of a notched bar. L. Jannin. Bull. Soc. d'Encour., 1922, **124**, 646—656.

The test piece is in the form of a bar 10 mm. square and 50—60 mm. in length, in the middle of which a semicircular notch is cut having a radius of 5 mm. so that 5 mm. of metal is left. One end of the bar is fixed and the other is hammered by hand in the direction tending to open the notch. Bending of the bar is stopped at the first indication of a crack in the bottom of the notch. The angle of bending is a function of the elongation as determined by ordinary methods, as is also the width (l) of the metal at the bottom of the notch, considered in relation to the original length (L) of the notch (10 mm.). The value $(L-l)/L$ multiplied by a factor to give L=100, is in close agreement with that obtained by the standard method. The resistance of steel is nearly proportional to the Brinell hardness, and the author proposes to multiply the value for the Brinell hardness by the supplement of the angle of bending in the notched bar test, divide the result by 1000 and term the number obtained the "coefficient of shock" (*coefficient de choc*) which would indicate the resilience of the steel. The coefficient is of course an abstract number from its origin.—C. A. K.

Carbon steels; Effect of longitudinal stress on the electrical resistance of ——. S. Fukuta. Sci. Rep. Tohoku Imp. Univ., 1922, **11**, 131—137.

The increase in the resistance of carbon steel is almost proportional to the applied stress. With increase in the carbon content of the steel the magnitude of this effect diminishes. Thus, with iron the rate of increase in resistance is less than with steel.—W. E. G.

Boiler plate [steel]; Effect of rate of loading on tensile properties of ——. H. J. French. Chem. and Met. Eng., 1922, **27**, 309—310.

The tensile strength, elongation, and reduction in area of steel, such as is used in railway fireboxes, are independent of the rate of loading at temperatures up to and including the blue-heat range (295° C.), above which the tensile strength alone appears to increase slowly with the rate of loading while the other properties remain constant. By increasing the load extremely slowly the tensile strength is increased and the ductility decreased at 156° C., while the reverse holds good for temperatures above 295° C. Only very slight differences could be discerned in the fracture of specimens broken under different rates of loading.—A. R. P.

Steels; Flow of —— at a low red heat, and scaling of heated steels. J. H. S. Dickenson. Iron and Steel Inst., Sept., 1922. [Advance copy.] 38 pp.

The author carried out on a number of steels, including carbon, nickel-chromium, high nickel, high chromium, and high-speed steels, and on the nickel-chromium alloy (Vikro), prolonged tensile tests at constant load and temperature, commencing at approximately 525° C. and increasing by increments of 50° C., also tests at constant load and slow uniform rate of heating. As a general deduction, the temperature at which a given load can be supported is higher, the shorter the duration of loading. The reduction of area increases as the test pieces are more rapidly broken and is sometimes accompanied by increased elongation. If the temperature be plotted against the logarithm of the duration of loading for the various steels almost straight lines are obtained, and this suggests that the samples behaved in accordance with the law governing the change of viscosity with temperature. The lines for nickel-chromium alloy and nickel chromium steel are inclined to those of the other steels. The first-mentioned (Vikro) is much superior at high temperatures (950° C.) but at lower temperatures (500° C.) only shows equal endurance to high speed steel. The maximum temperatures up to which the metals will support a load of 8·5 tons applied rapidly or for a short period, and the corresponding temperatures when the metals are expected to endure for considerable periods without sensible deformation, are: 0·3% carbon steel, 775°, 500°; nickel-chromium steel, 805°, 450°; high chromium steel, 800°, 520°; high-speed steel, 955°, 575°; nickel-chromium alloy (Vikro), 965°, 600° C. Scaling tests were made on a similar series of steels up to 1125° C., the specimens being exposed for 18 periods of 5¼ hrs. each and being scraped after each exposure. With a scaling rate fixed at 0·005 g. per sq. in. per hr., carbon steel and nickel-chromium steel could be used only up to 620° C., high-speed steel up to 710° C., 14% chromium steel up to 840° C., and nickel-chromium alloy up to 1070° C. Plotting the temperature against the logarithm of the scaling rate gave approximately straight lines. Micro-examination was made of the specimens heated at 900° C. for 24 hrs. and then heavily copper plated to hold the scale in position before sectioning. In the case of 25% nickel steel the strongly adherent lower layer of scale characteristic of steels containing nickel (Stead, J., 1916, 1018) was particularly well defined, and this explains the stepped scaling curve of this steel. The scale on the high chromium steel was barely visible; that on the nickel-chromium alloy unrecognisable.—T. H. Bu.

Carbon steels; Preliminary magnetic study of some heat treated ——. E. D. Campbell and E. R. Johnson. Iron and Steel Inst., Sept., 1922. [Advance proof.] 22 pp.

A uniform method of magnetisation was obtained by supporting a steel bar, 15 cm. long, vertically in the axial centre of a magnetising coil consisting of 1004 turns of wire wound over a length of 25 cm. The force with which a disc of annealed electrolytic iron was attracted by one pole of the magnetised bar was measured by means of a special balance. Four straight carbon steels were used for experiments involving heat treatment, the constitution of the steel being expressed in the form of concentration of alloying elements in mg.-atoms per c.c., thus correlating the atomic relations between solute and solvent in the steels with that of solutes and solvents in ordinary solutions. The different physical properties associated with magnetic properties are tabulated. Specific resistance increased rapidly with the carbide concentration; the permanent north field increased to a maximum with increase in the carbon content of the steel, but then decreased in the case of two hypereutectoid steels. The current required to demagnetise the bars indicated that the force field of carbon ions resulting from ionic dissociation of dissolved carbides will produce not only electrical but also magnetic resistance. The attractive force of the induced fields

with electrolytic iron increased much more rapidly than the inducing current, approaching more nearly a linear function of the square of the current; in the case of the hypereutectoid hardened steel the increase is more nearly a linear function of the current. The authors formulate a hypothesis for the mechanism of permanent magnetism in steel.
—C. A. K.

Iron and steel; Nitrogenisation of —— by sodium nitrate. L. E. Benson. Iron and Steel Inst., Sept., 1922. [Advance proof.] 6 pp.

Evidence of the formation of nitride in iron and steel was observed repeatedly when the metals were annealed in a salt bath (sodium nitrate 85, potassium chloride 15%) at 500° C. Steels of different composition were annealed in a bath of sodium nitrate and the rate of penetration of nitrogen was determined. The penetration into Armco iron was 0·15 mm. in 1 hr., 0·30 in 5 hrs., 0·70 in 20 hrs., and 2·0 mm. in 80 hrs. The rate of penetration into steel in general was slower than in pure iron, and was retarded considerably by the presence of carbon (pearlite). Manganese appeared to exert even more influence in this direction than carbon. A nitrogenised specimen or Armco iron showed no sign of nitride structure after heating in a muffle at 700° C. for 90 mins., and the nitrogen content was found to be only 0·0025%, which confirms the instability of iron nitride as observed by Tschischewski (J., 1915, 1012).—C. A. K.

High-speed steel; Manufacture and treatment of ——. H. K. Ogilvie. Iron and Steel Inst., Sept., 1922. [Advance proof.] 11 pp.

Although equally good steel can be made in the crucible and in the electric furnace, the cost per ton of sound billets is less in the electric furnace. In the crucible method, if small particles of tungsten compounds are not completely melted, hard spots form which may destroy fine toothed cutters; it is preferable to introduce the tungsten as ferrotungsten or tungsten-chromium alloy, rather than as tungsten powder. In this country it is not commercially possible to make good high-speed steel from turnings alone, but heavy clean scrap is used. The length of each heat should be shortened as much as possible, not exceeding 4½ hrs. for a 3- or 4-ton furnace. Electrode coolers should fit closely and attention must be paid to the furnace bottom and banks after each heat. The author recommends that no aluminium or other deoxidising substances be added in the ladle or moulds. When heating the metal to the temperature necessary for tapping, the steel, especially in smaller furnaces, occasionally becomes "wild," and it is useless to attempt to deoxidise with additions of ferrosilicon etc. The author's method is to cool the steel without any addition until samples taken at regular intervals show the metal to be sound. The ingots should be top poured in octagon moulds, the ingots being of less than 8" diameter and 10 cwt. weight. They are transferred to the reheating furnace when cooled to 200°—300° C. Surface cracks and flaws should be removed from the billets by grinding. In correctly forged cutters the steel should be structureless. If towards the centre the structure becomes coarser, fracture is liable to take place. Heavy duty cutters should be made of the 18% tungsten type of steel, hardened at 1300° C., and tempered at 590°—610° C., as this tempering treatment increases the toughness 100—150% over that produced by tempering at 220° C. The length of time the steel remains at the hardening temperature is most important; a bar just raised to 1300° C. gave the best load and deflection in a bending test. In hardening screw dies with fine teeth very little scale is sufficient to clog the teeth; a gas-fired carborundum tube furnace with a slightly reducing atmosphere was found to give no scaling whatever.—T. H. Bu.

[Nickel chromium] steel; Change in volume of [air hardening] —— during heat treatment. L. Aitchison and G. R. Woodvine. Iron and Steel Inst., Sept., 1922. [Advance proof.] 16 pp.

Specimens of steel containing 4·64% Ni and 1·53% Cr, rolled to round bars, were heated in a dilatometer similar to that used by Andrew (*cf.* J., 1920, 452 A) and the change in volume noted. Following a gradual expansion, a marked contraction took place at 685°—745° C., the steel expanding again at higher temperatures. The steel contracted in a normal way during cooling from 850° to 285° C., but expanded in the interval 285°—150° C., contracting again whilst cooling to atmospheric temperature. The final volume showed, however, a definite increase over the initial volume, and a steel treated in this way formed the basis of subsequent experiments and was termed "semi-standard" steel. Repeated heating and cooling of the semi-standard steel showed that generally the first heating caused an expansion of the metal, followed by contractions in the later heatings, and 5—6 heatings at 200°—500° C. were necessary to secure a stable volume which was greater at 200°—300° C. than when the metal was heated to 400°—500° C. only once. Continuous heating at 200° C. or 100° C. for 6 days resulted in a contraction equal to that produced by repeated heatings at the higher temperatures.
—C. A. K.

Chromium steels and their recent applications. L. Guillet. Rev. Mét., 1922, 19, 499—504.

The heating curve of stainless steel containing 13% Cr shows two transformation points at 710° C. and at 780° C.; on cooling these transformations take place at 680° C. and 320° C. The material may be made sufficiently soft for working either by heating to 900° C. and cooling very slowly, or by annealing for a long time at 750° C. followed by either slow or rapid cooling. The best temperature for forging steel containing 13% Cr and 0·35% C is between 1000° and 1250° C. and preferably as near the upper limit as possible. The maximum tensile strength and elastic limit are obtained by quenching in oil from 900° C. Annealing at temperatures above 400° C. rapidly reduces the figures obtained for these properties and only slowly increases the elongation, but the higher the annealing temperature, especially if above 600° C., the greater the resistance to shock. 13% Cr steel retains its hardness up to about 500° C., except for a slight softening at 300° C., and offers the greatest resistance to corrosion after quenching in oil from 950°—1050° C., after which it has a hardness of 500—600.—A. R. P.

Steel plates containing zirconium and other elements; Manufacture and properties of ——. G. K. Burgess and R. W. Woodward. U.S. Bureau of Standards, Tech. Paper No. 207, 1922. 49 pp.

The authors have prepared and studied 193 heats of steel containing as principal variable elements, carbon, silicon, nickel, aluminium, titanium, zirconium, cerium, and tungsten. None of the steels presented any difficulty in rolling, except those containing boron, which forms a complex eutectic fusible at the ordinary rolling temperature. A type of steel recommended for structural work and having a tensile strength of about 300,000 lb. per sq. in., contains 0·4—0·5 C, 1—1·50% Si, 3—3·25% Ni, and 0·6—0·8 Mn. The metal should be deoxidised with a simple deoxidiser such as aluminium, but the addition of more costly alloying elements does not lead to any material advantage. Zirconium, like titanium and aluminium, acts as a scavenger and any excess remains in the metal in the form of square bright yellow inclusions which may be detrimental to the steel if segregation occurs. Most of the other alloying elements go into solution and produce a martensitic structure in the air-cooled specimens, a larger quantity of copper than of the other elements being required to produce the effect. Besides showing the martensitic structure when air-cooled, steels containing cerium and uranium exhibit characteristic inclusions.—C. A. K.

Corrosion of iron and steel. R. Hadfield. Proc. Roy. Soc., 1922, A **101**, 472—486.

Tests have been carried out to ascertain the effect of a small percentage of copper upon the resistance of steel to corrosion. It is shown that a small copper content, from 0·16 to 0·25%, is beneficial both in the case of bare metal and of metal coated with rolling scale exposed to atmospheric corrosion, especially in a sulphurous atmosphere. Steel with the scale removed is more resistant than steel with the scale on. When exposed to the action of sea-water, ordinary steel corrodes the more rapidly initially. Subsequently the rate of corrosion of both varieties of steel diminishes, indicating a certain degree of self-protective action which is rather more pronounced for the ordinary variety. At the end of 16 weeks, the total corrosion of copper steel containing 0·268% Cu was still less than that of ordinary steel. The comparative behaviour of the material with scale on and with scale removed resembled that found in the case of atmospheric corrosion There was little to choose between the two varieties in the matter of resistance to corrosion by tap-water. The specimens were tested with their rolling scale removed, and it was found that tap-water, though initially less corrosive than sea water, is more corrosive over a long period. Both varieties were initially rapidly attacked by 50% sulphuric acid solution, but after 3 weeks' exposure the copper steel was only very slowly corroded, while the rate of corrosion of the ordinary variety remained unaltered. Tests with 20% sulphuric acid solution confirmed the superiority of the copper steel. The results are in agreement with the conclusions of Buck (J., 1921, 262 A) and of Bauer (J., 1921, 393 A) as to the superior resistance to atmospheric corrosion of mild steel containing a small percentage of copper, the superiority amounting to about 10% in pure air and to about 25% in an industrial atmosphere. No superiority is shown by copper-steel when immersed in tap water, and it is possible that the initial superiority shown by this variety when exposed to sea water may be annulled and even reversed on long exposure.—J. S. G. T.

Brass and bronze; Development and manufacture of high tensile ——. O. Smalley. Inst. Brit. Foundrymen, 1922. Engineering, 1922, **114**, 187—189, 218—221.

The modifications of the mechanical and physical properties of a pure brass by the addition of other alloying elements has been studied in detail. The examination of brass containing 1·0—5·8% Al showed that the presence of 1% Al is equivalent to about 5·6% Zn in its effect on the general physical properties, so that a brass containing 70% Cu, 26·5% Zn, and 3·5% Al possesses the principal features of ordinary Muntz metal. Small proportions of aluminium increase remarkably the yield-point and strength of both 70/30 and 59/41 brass, with a corresponding loss in ductility. More than 3·5% Al causes the ductility of a 70% copper brass alloy to fall rapidly, and in the 59/41 series 1·35% Al appears to be the limiting amount of aluminium for rapid increase of strength, though the maximum strength is not reached until 3·0% Al had been added. All β-aluminium brasses, regardless of the chemical composition, suffer from heat fragility over a long interval, which extends from 315° to 455° C. for the Cu-Zn series, and from 226° to 558° C. for β-brasses of the Cu-Zn-Al series. β-Brasses of maximum tenacity are brittle alloys and slight overheating renders them unsafe in use owing to the abnormally rapid crystal growth at temperatures above 700° C. Manganese brass is prepared from cupro-manganese in preference to ferro-manganese, which is difficult to alloy completely. Considered as a zinc-replacing element 1% Mn is equivalent to 0·8% Zn. Manganese is of chief value as a deoxidiser and when added in excess of the amount required for deoxidation trouble is experienced and defective castings result from the tendency to oxidation. A better cohesion between adjacent grains is noticed, which suggests that manganese may be of value as a toughening agent. Tin improves the corrosion-resisting properties of brass; in complex brasses of high ductility 0·7% is the maximum amount which should be used. The quantity of tin which brass will take into solution was found to be determined by the zinc content, *i.e.*, in the α-series an 80/20 brass dissolves 5% and a 70/30 brass less than 1% Sn. The addition of 0·5% Sn increases the yield-point and maximum strength of cast brass 2·25 and 1·3 tons respectively without affecting the other mechanical properties. Further addition of tin hardens the alloy without increasing the strength and the alloy finally becomes brittle. There is no difficulty in forging tin brasses, but 1% Sn is the limit of practical utility.—C. A. K.

Red-brass; Volumetric determination of tin and antimony in ——. F. J. Mück. Chem.-Zeit., 1922, **46**, 790.

Two grams of the alloy is dissolved in 20 c.c. of nitric acid, the solution evaporated to 5 c.c., 100 c.c. of boiling water added, the liquid boiled for 5 min. and the precipitate of antimonic and stannic acids filtered off, washed with hot 5% nitric acid and dissolved in 15 c.c. of strong sulphuric acid and 10 c.c. of strong nitric acid. 2—3 g. of potassium sulphate and 0·5 g. of tartaric acid are added and the solution is evaporated to syrupy consistency. After cooling, 180 c.c. of water and 7 c.c. of hydrochloric acid are added and the solution is boiled for 5 mins., cooled, and titrated with permanganate for antimony. Another 30 c.c. of water and 60 c.c. of hydrochloric acid are added and the tin is reduced by boiling with 2—3 g. of antimony and titrated with iodine as usual.
—A. R. P.

Brass; Dezincification of —— [*by solution*]. R. B. Abrams. Trans. Amer. Electrochem. Soc., 1922. [Advance copy.] 12 pages.

The dezincification of brass takes place in two stages; in the first the brass as a whole is dissolved, in the second the copper in solution is re-deposited with solution of an equivalent amount of brass. The second stage does not take place unless there is a means of holding the copper solution in contact with the brass, such as the presence of a membrane or of a large excess of dissolved copper. Under natural conditions of weathering the membrane may be supplied by a layer of insoluble zinc or copper salt or by contact of the metal with a cover of wood or metal. Without this protection the soluble copper salt is washed away and the brass dissolves as a whole; with it the metal gradually turns into a mass of solid copper which is generally deposited in two layers.—A. R. P.

Aluminium-silicon alloys; "Modification" of ——. J. J. Curran. Chem. and Met. Eng., 1922, **27**, 360—361.

Aluminium-silicon alloys are "modified" by melting them under a layer of an alkali fluoride which according to Guillet simply fluxes off oxide inclusions and gives a more satisfactory structure. The author finds that a "normal" aluminium-silicon alloy shows a "modified" structure after melting with a little sodium, part of which remains in the final alloy, and suggests, therefore, that in the use of alkali fluorides part of the alkali metal is reduced by the silicon (which volatilises as fluoride) and its presence in the final alloy is the real cause of the "modified" structure.—A. R. P.

Tin alloys containing iron; Analysis of ——. N. Welwart. Chem.-Zeit., 1922, 46, 777.

A discussion of Meyer's paper (J., 1922, 256 A) pointing out a number of precautions that must be taken to ensure accurate results and suggesting certain minor modifications that shorten the time required for an analysis.—A. R. P.

Nickel, monel metal, stellite, stainless steel and aluminium; Thermal expansion of ——. W. H. Souder and P. Hidnert. U.S. Bureau Standards, Sci. Paper 426, 1922, 497—519.

The average coefficient of thermal expansion between 0° and 600° C. of commercial nickel was found to be 14·9—15·7×10^{-6}, of monel metal 15·9—16·7×10^{-6}, of stellite 13·6—17·1×10^{-6}, of stainless steel 11·2—12·1×10^{-6}, of aluminium 29·3—29·5×10^{-6}. The expansion curve of nickel is, with the exception of a small break at 350° C., quite regular, while that of stellite shows irregularities between 300° and 500° C. The curve of monel metal is regular up to 600° C., as is that of stainless steel up to the critical region (825°—850° C.). The aluminium curve may be expressed by the empirical equation: $L_t = L_0\,[1+(21{\cdot}90t+0{\cdot}012t^2)10^{-6}]$.—A. R. P

Uranium; Glacial acetic acid method for determining —— *in carnotite.* W. W. Scott. J. Ind. Eng. Chem., 1922, 14, 531—532.

About 0·5 g. of the ore is boiled with 40 c.c. of dilute nitric acid (1:1) until decomposed completely, the solution evaporated to dryness, the residue baked for a few mins., and then boiled for 5 mins. with 25 c.c. of a mixture of glacial acetic acid and nitric acid (100:5). The solution is filtered, the insoluble portion washed with the acid mixture, the filtrate, which contains all the uranium, is evaporated to dryness, the residue heated over a burner until it turns black, and the extraction with the acid mixture repeated. The filtrate thus obtained is evaporated, the residue heated, dissolved in 10 c.c. of nitric acid and 40 c.c. of water, the solution partly neutralised with ammonia, and solid ammonium carbonate added until the uranium carbonate first precipitated is re-dissolved. After the addition of a further 3 g. of ammonium carbonate and 5 c.c. of ammonia the solution is filtered, the residue washed with hot water, the filtrate acidified with nitric acid and boiled to expel carbon dioxide. Excess of ammonia is then added and the solution boiled until all the uranium is precipitated, as is shown by the yellow-coloured solution becoming colourless. The precipitate is collected, washed with a small quantity of 2% ammonium nitrate solution, ignited and weighed as U_3O_8.—W. P. S.

Metals; Beilby's theory of the amorphous state of ——. C. Benedicks. Rev. Mét., 1922, 19, 505—513.

The author reviews critically the facts on which Beilby's theory of the amorphous state of metals is based. Several of the results obtained by Beilby may be satisfactorily explained without assuming the presence of a thin, mobile, transparent, amorphous film of metal. Thus, the surfaces of polished specimens of antimony and copper often show spots of considerably less reflecting power than, or of a different colour to, the rest of the metal, which Beilby assumes to be due to cavities covered with a thin film of amorphous metal, whereas the author has found that these effects are produced by inclusions of antimony trioxide or cuprous oxide. With regard to the increase of hardness of the polished surface it has been shown by Osmond that this is probably due to particles of the polishing medium becoming embedded in the metal. While it is fair to assume that, if the amorphous phase exists on the surface of a metal, it can also exist in the interior, the assumption that its presence there, after subjecting the metal to a hammer-hardening process, is the cause of the increased hardness observed does not accord with past experience. The following theory is advanced to explain the increase of hardness of metals on hammering: After deformation, an originally plane surface may exhibit a "parallel translation," in which each particle slides over the next in a manner similar to a pile of books that has been pushed sideways, or it may undergo a "proportional translation," in which the lamellæ have a macled aspect, *i.e.*, they do not really slide but a rotation of the crystal element takes place. In the former case, the amount of deformation possible is unlimited, the lamellæ simply sliding over one another, and there is no increase in hardness. In the second case, however, the amount of deformation possible is strictly limited by the characteristic angle of the macles and each deformation the metal undergoes increases the resistance to further deformation, *i.e.*, increases the hardness by making the lamellæ grow into each other, an operation that becomes more difficult to perform the further it is carried out.
—A. R. P.

Hardness of metals; An accurate method of determining the —— *with particular reference to those of a high degree of hardness.* R. L. Smith and G. E. Sandland. Proc. Inst. Mech. Eng., 1922, 1, 623—641.

By a suitable modification of the Brinell formula it is possible to obtain truly relative hardness figures from which may be calculated the load required to give a constant impression. The modified hardness numeral suggested is calculated from the expression: Brinell hardness number at 1000 kg. ×$(0{\cdot}9+0{\cdot}4/d^2)$, where d is the diameter of the impression in mm. The figure arrived at is not strictly accurate where the hardness exceeds 525 Brinell, owing to the deformation of the ball, and the authors have calibrated natural pyramidal diamonds to replace the steel ball and so obtain substantially correct values for hardness for the higher ranges. The diamonds have to be calibrated individually owing to the difficulty in grinding true hemispherical surfaces. The load applied with the diamond test is light and the impression shallow, and the test is very sensitive therefore to the surface hardness of the material. A more accurate estimate of the maximum stress is possible with the modified hardness numbers, as they lie on a straight line which passes through the origin, and only one conversion factor (0·23) is required over the range 30—90 tons for plain carbon steels.—C. A. K.

Brinell machine attachment for use with small specimens. E. D. Campbell. Iron and Steel Inst., Sep., 1922. [Advance proof.] 8 pp.

The large regular balance corresponding to a pressure of 500 kg. on the ball of a Brinell machine was replaced by a light balance constructed of brass tubing, using also separate holders for balls of 5 and 2 mm. diam. The light balance was adjusted so that the impression produced when viewed through a 16-mm. objective would appear of the same size as an impression made with a 10-mm. ball under a 3000 kg. load viewed through the standard 48-mm. objective. The final weight of the balance was adjusted by experimental comparative calibration.

The instrument was adapted to the use of softer metals by calibrating similarly a 5-mm. ball and observing the impression through a 32-mm. objective. Certain precautions are necessary in the determination of hardness by means of small impressions. The metal must be polished almost to the same degree as for metallographic work and a film of oil applied to lessen friction during the test. The application of the load should be gradual and the full load should be maintained at least 1¼ min.
—C. A. K.

Metals; Tearing tests on ——. H. L. Heathcote and C. G. Whinfrey. Chem. and Met. Eng., 1922, **27**, 310—311.

Structural metals which have been tested to withstand certain definite stresses may fail under apparently smaller stresses owing to the concentration of the stress overstraining the piece at the surface where the section changes, and thereby causing the metal to tear. The resistance to tearing of a metal may be found by cutting a thin sheet in two places and bending the tongue of metal thus formed at right angles to the sheet and the two wings, which should be of equal size, into alinement with the tongue in the opposite direction. The specimen is then gripped in a delicate testing machine by the tongue and wings and load is gradually applied until the metal tears as viewed by a "strong" glass. The average of 5—6 tests gives the pull required to tear the metal in two places and bend and unbend a width equal to that of the specimen. By carrying out tests on specimens of width x in. and y in., and assuming that P and p are the pulls required to tear, bend and unbend material which is t in. thick, then the actual tearing force F per linear inch is given by the equation: $F=(px-Py)/2t(x-y)$. The results obtained agree more closely with those given by the notched bar impact test than with those obtained in the ordinary tension test.—A. R. P.

Moulding sands [for iron foundries]; Factors influencing the grain and bond in ——. C. W. H. Holmes. Iron and Steel Inst., Sept., 1922. [Advance proof.] 22 pages.

In judging the value of sands for grey-iron founding, the mechanical and physical properties are of equal importance to the chemical analysis. The most successful moulding sands contain both mobile or hydrated bonding material capable of transference from grain to grain and static bonding material firmly attached to the surface of the grains. The bond absorption value obtained on raw sand is greatly modified by mechanical treatment. Appreciable degradation of the sand grains occurs during the usual mechanical preparation, and in view of the fact that the degradation may be excessive, the bond distribution factor is a very important characteristic of sands. No single test is sufficient to judge the practical value of moulding sands.—T. H. Bu.

Patents.

Iron and steel; Process for the direct manufacture of ——. L. P. Basset. E.P. 159,475, 24.2.21. Conv., 24.2.20.

Fuel in an extremely divided condition, *e.g.*, finely pulverised coal or hydrocarbon, and superheated air in suitable proportions to produce only carbon monoxide, are injected into the lower end of an inclined rotary furnace. The ore is mixed with a quantity of carbon insufficient to reduce the whole of it, and with basic fluxes, and the mixture is fed into the upper end of the furnace. The fraction of the ore escaping reduction serves, with the help of the basic slag, to prevent the reduction of the calcium phosphates, silicates, etc. in the ore and thus avoid phosphorisation of the metal.
—T. H. Bu.

Iron and steel; Process of desulphurising ——. H. Koppers. E.P. 162,618, 28.4.21. Conv., 28.4.20.

After treatment of the molten iron in the usual manner for the removal of phosphorus, manganese, silicon, and the like, the slag is removed and a highly basic slag put on, in which are immersed blocks of dense carbon of about the same sp. gr. as the slag, whereby calcium is liberated and combines with the sulphur in the iron. The dense carbon may consist of coke overheated in the carbonisation process, or of perforated or unperforated blocks of finely ground coke briquetted under high pressure with tar as a binder. The slag layer is revivified by passing a current of air through or over it.—T. H. Bu.

Silicon steel and other metals and alloys; Methods of refining ——. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 183,217, 15.4.21.

The molten metal is subjected to a periodically varying magnetic field so as electromagnetically to expel occluded slag particles, which are caused to rise to the surface. The metal is then mechanically separated from the supernatant slag. Silicon steel refined in this way and with the sulphur not greater than 0·10% shows on the average a reduction of 12% in hysteresis losses.—T. H. Bu.

Iron and steel; Apparatus for the determination of the percentage of carbon in ——. C. J. G. Malmberg and J. G. Holström. E.P. 184,215, 11.3.21.

A specimen of iron or steel is subjected to repeated magnetisation and demagnetisation between two chosen values of the magnetising force. The difference between the two magnetic fluxes through the specimen is taken as an indication of the carbon content, and is measured by the induction in a wire wound round the specimen or on any part of the circuit of which the specimen forms a part.—C. A. K.

Steel alloy; Non-corrosive ——. W. Belleville. U.S.P. 1,424,612, 1.8.22. Appl., 16.6.21.

A steel alloy contains approximately Ni 15·5%, C less than 1%, Si 0·3%, Mn 0·5%, Cr, S, P each less than 0·1%.—C. A. K.

Alloy for forging steel and method of producing same from nickel ore. L. P. Burrows; L. B. Archer executrix. U.S.P. 1,424,710, 1.8.22. Appl., 20.1.20.

Crushed nickel ore is subjected to the action of reducing gas in a closed chamber until the oxygen content of the ore is removed. The refined ore is smelted, and the metallic product broken up and disintegrated by exposing it to the atmosphere. The disintegrated material is then subjected to a low red heat without oxidation until its weight is reduced about 20%.—T. H. Bu.

[Iron] alloy. W. H. Smith, Assr. to The Cleveland Brass Mfg. Co. U.S.P. 1,424,782, 8.8.22. Appl., 23.3.18.

The alloy contains 50—85% Fe, 1—10% Ni, 1—3% Si, and the remainder, chromium.—A. R. P.

Iron ores, iron and steel, and coke used in the metallurgy of iron; Process of desulphurising ——. W. I. Estabrooke and D. D. Jackson, Assrs. to J. T. Pratt, D. D. Jackson, and J. D. Sears. U.S.P. 1,426,054, 15.8.22. Appl., 13.7.20.

A halogen (chlorine) is introduced into the molten or heated material, whereby a volatile sulphur halide is formed.—C. A. K.

Electrolytic iron; [Bath for the] production of ——. M. Schlötter. G.P. 310,043, 13.12.17.

Alcohols, such as glycerol or glycol, are added to the ordinary bath for the deposition of electrolytic iron, which is then obtained so soft that it may be cut with a knife. For example, the bath may consist of a solution of 280 g. of ferrous chloride and 2 g. of hydrogen chloride in a litre of water to which 400 c.c. of pure glycerol has been added. —A. R. P.

Iron and steel; Process for covering —— with a rust-resisting coating. W. Schmidding. G.P. 310,756, 11.7.18.

The iron or steel articles are dipped in a solution containing phosphoric acid, zinc, and calcium, together with an oxidising substance which yields oxygen in the nascent state or which, in the presence of acids, yields hydrogen peroxide. The evolved oxygen prevents the formation of slime, shortens the time required and hastens the chemical reaction.—A. R. P.

Iron and iron ores; Removal of sulphur from ——. O. Baumann. G.P. 356,039, 13.3.19.

The ores are fused with barium sulphate, and the product is used in the ordinary smelting operations for removing sulphur. Barium has a greater affinity than calcium for sulphur, and so carries the sulphur into the slag.—A. B. S.

Shaft furnaces and the like. E. F. Chaudière. E.P. 161,971, 19.4.21. Addn. to 137,168 (J., 1920, 179 A).

A central core consisting of concentric iron columns protected by a refractory material is fitted vertically in a shaft furnace in line with the chimney. Suitable openings into the iron column allow a proportion of the air which has passed through the calcined material to be admitted direct to the chimney to assist the draught, or the heated gases above the combustion zone may be withdrawn for the purpose of recuperation of heat. The direction and volume of flow in the core is regulated by a reversible fan and by dampers.—C. A. K.

Furnaces; Open hearth ——. G. L. Danforth, jun. E.P. 183,247, 20.4.21.

The ports of an open-hearth furnace are arranged so that the air and gas from separate ports meet in a combustion chamber of diminishing sectional area towards the inlet to the furnace. In the furnace the cross-sectional area is gradually enlarged, thus allowing the gases to expand. The effect is that of a Venturi tube, and the minimum area of the port entering the furnace may be less than the combined areas of the gas and air ports opening into the combustion chamber.—C. A. K.

Crucible furnaces; Gas heated ——. T. Teisen. E.P. 183,394, 16.11.21.

In a crucible furnace of the type in which gas is admitted through a vertical burner passage, air is directed into this passage at right angles, either tangentially, or otherwise, so as to cause the air to swirl around the gas stream and so protect the lining from excessive heating.—C. A. K.

Furnace; Hearth smelting or heating ——. Façoneisen-Walzwerk L. Mannstaedt und Co. Akt.-Ges., and H. Bansen. E.P. 184,252, 4.5.21.

The furnace is heated by twin burners on either side of the furnace, and extending the full length of the furnace chamber. After passing partially across the furnace the gases travel longitudinally and pass out of the furnace through recuperators. Each pair of burners is provided with a regenerator, and at any one time one burner acts normally whilst the second is used as a flue for part of the furnace gases through the regenerator. The burners situated opposite to one another are directed in slightly different directions in the vertical plane. The combustion chamber may be constructed with circular cross-section so that the gas and air from the burners enter the combustion chamber tangentially.—C. A. K.

Cupola and blast furnaces; Process for improving the operation of ——. Vulkan-Werk Rheinshagen und Co. G.P. 354,469, 15.8.20.

Water, in a liquid form, is introduced into the furnace by the blast, whereby an economy is effected in the fuel consumption, the iron is improved in quality, and the lining of the furnace is protected.—A. R. P.

Tungsten wires; Manufacture of drawn ——. Patent-Treuhand-Ges. für Elektrische Glühlampen, m.b.H. E.P. 163,014, 6.5.21. Conv., 7.5.20.

Drawn tungsten wires are produced from pressed or sintered rods which contain in their cross-sections zones which differ from the main body and if necessary from one another in their chemical or physical properties, or in the composition, nature, or relative proportions of the constituents, all cross-sections throughout the length being in general alike. Thus filaments may be produced from tungsten with various sizes of grain, or from tungsten with various additions of thorium dioxide, or from tungsten containing molybdenum, uranium, thorium, tantalum, vanadium, chromium, carbon, phosphorus, etc. or mixtures thereof. Drawn tungsten wires of definite structure can be methodically produced from such material. —J. S. G. T.

Precious metals [e.g., gold]; Process for the metallurgical treatment of ores containing —— [and a volatile metal, e.g., antimony]. Blei- und Silberhütte Braubach A.-G. E.P. 167,741, 28.4.21. Conv., 12.8.20.

Ores containing gold or other precious metal, together with large amounts of volatile metals, such as antimony, arsenic, zinc, and lead, are smelted, in shaft furnaces of the type used in the production of pig-iron, with suitable additions to give a slag of a higher melting-point than the volatilisation-point of the one constituent (*e.g.*, antimony oxide), and a suitable concentration metal (*e.g.*, copper or pig-iron) in which to collect the precious metal. —A. R. P.

Gold; Recovering —— and apparatus therefor. O. C. Knipe. U.S.P. 1,426,746, 22.8.22. Appl., 31.10.21.

The interior of an open hollow drum is lined with a porous fabric coated with grease, which retains the particles of gold when a liquid containing gold in suspension is rotated rapidly within the drum. —C. A. K.

Noble metals; Recovery in a pure state of the ——, particularly gold and platinum, by chlorination. C. Bennejeant. G.P. 355,886, 14.1.21.

Alloys or ores of the noble metals are strongly heated with chlorine compounds so as to volatilise the chlorides of commoner metals whilst the chlorides of nobler metals remain in the residue. —A. B. S.

Precious and other metals; Joining together [welding or soldering] of ——. J. Maurer. E.P. 183,188, 18.3.21.

A SOLDERING paste for use in joining metals consists of a mixture of finely divided metals identical with the metals to be welded, the oxides of the same metals, a reducing agent, a flux, and a binding medium, the latter being preferably vaseline. Powdered carbon is a suitable reducing agent. —C. A. K.

Copper; Process for the autogenous [electric] welding of ——. H. Cauzler. G.P. 355,906, 7.10.20.

THE electrode consists of a copper rod containing gold, or gold and silver, together with phosphorus, manganese, silicon, or boron. The welds obtained have a high tensile strength, are readily machinable, and have a great resistance to attack by acids. —A. R. P.

Copper; Process for the extraction of —— from its ores. P. W. Nevill and H. Soanes. E.P. 172,926, 20.7.21. Conv., 13.12.20.

FINELY crushed copper ore, containing the bulk of the copper in an oxidised form, is treated with water and ferrous sulphate, either with or without the addition of sodium chloride, or with dilute sulphuric acid, and the resulting pulp is heated for a short time by means of steam while finely divided metallic iron is added to reduce all the copper compounds to a metallic sponge, which is then separated from the gangue by elutriation, flotation, or other means.—A. R. P.

Nickel ores; Process of treating —— and product resulting therefrom. L. P. Burrows: L. B. Archer executrix. U.S.P. 1,424,711, 1.8.22. Appl., 4.5.20.

STEAM is suddenly expanded, and without condensation, any water vapour held in suspension is separated. The resulting gaseous product is heated and crushed nickel ore is subjected to its action at red heat in a closed chamber for about 5 hours. —T. H. Bu.

Nickel or nickel-rich alloys; Process for the preparation of —— from low-grade nickel-iron alloys. M. Stern. G.P. 354,219, 23.3.18.

IRON-NICKEL alloys containing a low percentage of nickel are subjected in the form of turnings to oxidation, either by moistening them with a rust-producing substance, such as magnesium chloride solution, and heating the mass in the air, or by passing air or oxygen over the heated metal, so that the heat of oxidation of the iron raises the temperature to such an extent that the mass melts, the greater part of the iron being oxidised and slagged off while the nickel is recovered in nearly pure form or as a high-grade ferro-nickel alloy. —A. R. P.

Nickel; Process for the preparation of agglomerates of pure —— from crude nickel oxide. Soc. Anon. "Le Nickel." G.P. 355,887, 8.6.21. Conv., 21.4.21.

CRUDE nickel oxide is heated in a closed vessel with solid, liquid, or gaseous reducing agents to such a temperature and for such a time that it is reduced to metal except for a small quantity. The charge is powdered and washed with dilute hydrofluoric acid, then dried, and pressed into the desired shape. The shapes are heated in a closed vessel first alone, then with the successive addition of powdered carbon and lime.—A. R. P.

Zinc-smelting furnace; Vertical retort ——. A. Jones. U.S.P. 1,424,825, 8.8.22. Appl., 19.2.21.

THE furnace consists of a chamber containing a number of vertical retorts arranged in rows; a fixed condenser placed between each pair of rows communicates with each retort in these rows.—A. R. P.

Zinc and other volatile metals or metalloids; Process for the distillation of —— from ores. W. Troeller. G.P. 353,797, 10.10.13.

THE ore mass is mixed with a solid fuel and the mixture charged into a discontinuously working converter of the Huntington-Heberlein type, provided with either artificial external cooling appliances or extra thick walls. The furnace is fired with gaseous or liquid fuel or with coal dust, which is burnt in such a manner that the flame envelopes the ore mixture and the reducing gases permeate the porous mass and thus effect more complete reduction. The gases may also be burnt inside the ore mass after the manner of flameless combustion. From time to time the air supply is interrupted, so that the unburnt gases permeate the mass, thus effecting still more efficient reduction, while part of the metal is simultaneously recovered in liquid form.—A. R. P.

Zinc oxide and similar material containing lead; Process for removing lead from ——. H. Pape. G.P. 354,096, 16.1.17.

THE finely ground oxide is mixed with quicklime or slaked lime and water to a thick slime, which is stirred into a large bulk of water and the insoluble zinciferous material separated by filtration. The solution is treated with just sufficient of a compound of sulphuric, carbonic, or chromic acid to precipitate the lead, and the clear liquor is used instead of water for the first part of the process, while the precipitate is treated in the usual manner for the recovery of its lead content. Coarse material, such as roasted or sintered ore, is mixed with lime and water before grinding, and the mixture is then ground wet and treated as before. —A. R. P.

Zinc dust; Process of manufacturing ——. T. Kato. U.S.P. 1,425,661, 15.8.22. Appl., 26.11.19.

METALLIC zinc is volatilised in a retort from which air is excluded, and the zinc vapours are diluted with a non-oxidising gas and cooled quickly. —D. F. T.

Separating process. [Concentration of ores.] R. Ellis. U.S.P. (A) 1,425,185, (B) 1,425,186, and (C) 1,425,187, 8.8.22. Appl., (A) 15.4.18, (B) 2.4.19, (C) 20.8.15. (C) Renewed 25.4.21.

(A) The comminuted ore is mixed with water and an oily liquid, and then with a material which will give anions having a greater valency than two. The mixture is aerated and the froth separated. (B) After the addition of oil and before aeration a material capable of making the contact potential of the oil more negative is added. (C) A process for the concentration of mixed ores includes the use of a solution having a selective action for the oxidised portion of the ore and of a solution containing anions having a valency greater than two and cations having a valency greater than one. —C. A. K.

Flotation process. R. Luckenbach, Assr. to Luckenbach Processes, Inc. U.S.P. 1,425,327, 8.8.22. Appl., 9.2.20.

THE tar product from the distillation of "greasewood" is added to the pulp, which is then aerated, and the froth separated.—C. A. K.

Flotation process for dressing mineral mixtures. Maschinenbau-Anstalt Humboldt. G.P. 353,726, 17.8.20.

THE mixture before passing into the flotation vessel is treated with a mixture of vaporised or gaseous wetting media, such as oils, hydrocarbons, etc., and vaporised or gaseous media affecting the capacity for adsorption and suspension of the constituents of the mineral mixture. If desired the mineral mixture may be separately submitted to the action of the two kinds of media. The consumption of reagent for increasing the adsorption coefficient is in this manner reduced.—J. S. G. T.

Magnetic separator. W. E. F. Bradley. U.S.P. 1,425,235, 8.8.22. Appl., 21.9.18.

A STREAM of material to be treated is subjected to the action of a series of electro-magnets arranged in sequence with the pole faces directed downwards. The magnets are energised in groups of "relatively displaced cyclic current phases, the algebraic sum of the currents of a group alternating cyclically from a positive value to a negative value and back to positive."—C. A. K.

Alloy. S. Mayer and W. James, Assrs. to Magno Storage Battery Corp. U.S.P. 1,425,330, 8.8.22. Appl., 23.6.21.

AN alloy of Sn 50, Pb 25, Zn 17, and Sb 8%.
—C. A. K.

Ores; Method of reducing ——. E. C. King. U.S.P. 1,425,386, 8.8.22. Appl., 23.10.20.

A CARBONACEOUS material and an oxidising agent are introduced below the surface of a bath of molten metal produced from the ore, and further quantities of the ore are concurrently fed on to the surface of the bath.—A. R. P.

Zirconium alloy and process of making same. F. M. Becket, Assr. to Electro Metallurgical Co. U.S.P. 1,425,572, 15.8.22. Appl., 1.10.20.

A LOW-CARBON ferro-alloy consisting essentially of iron, silicon, and zirconium is made by smelting in the electric furnace a charge comprising silica, a zirconium ore, a carbonaceous reducing agent, and a source of iron. The charge is proportioned to yield an alloy containing silicon in at least as high proportion as the zirconium, thus preventing the formation of zirconium carbide in interfering quantities.—H. H.

Metals from ores; Process of extracting ——. S. McKirahan, Assr. to F. A. Fuller. U.S.P. 1,425,667, 15.8.22. Appl., 14.2.18.

FINELY comminuted, oxidised ore is mixed with sodium chloride and heated to a temperature above 1000° C. The metal in the ore sublimes as chloride.
—D. F. T.

Phosphor metals; Method of producing ——. S. L. Nicholson, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,425,679, 15.8.22. Appl., 29.11.20.

PHOSPHORUS vapour is brought into contact with a metal heated to a temperature below its melting point. The metal is melted subsequently and cast into ingots.—C. A. K.

Metals; Process of freeing —— from copper. M. O. Sem, Assr. to Det Norske Aktieselskab for Elektrokemisk Industri. U.S.P. 1,425,701, 15.8.22. Appl., 4.4.19.

METAL containing copper is melted and treated with a sulphide of the same metal, and the copper sulphide is separated from the purified metal.
—C. A. K.

Electroplating; Process and apparatus for ——. W. E. Belke. U.S.P. 1,426,141, 15.8.22. Appl., 15.3.22.

A BATH for carrying out electroplating operations is provided with an arrangement of pipes and valves at the bottom whereby the electrolyte may be withdrawn in part to a filtering apparatus situated above the tank, and means are provided to discharge the filtered liquid on to the surface of the bath.
—A. R. P.

Tin and lead; Electrolytic production of adherent deposits of ——. M. Schlötter. G.P. 299,791, 17.2.17.

THE articles to be plated are first coated in an alkaline bath, the chief part of the deposit being afterwards made in an acid bath. This double treatment avoids the drawbacks of either an acid or alkaline bath, when used alone.—A. B. S.

Tin; [Electrolytic] process of depositing —— free from pores. M. Schlötter. G.P. 299,794, 8.3.17.

TIN free from pores is deposited by the electrolysis of alkaline stannate solutions free from acid radicles and made up principally or entirely with caustic potash.—J. S. G. T.

Tin; Process for recovering —— [from concentrates]. H. H. Alexander, Assr. to American Smelting and Refining Co. U.S.P. 1,426,341, 22.8.22. Appl., 26.5.17. Renewed 17.11.21.

TIN concentrates are mixed with carbonaceous matter and the mixture is sintered until approximately 70% of the sulphur contained in the mixture has been removed. The resulting mass is broken up into suitable-sized lumps which are mixed with carbonaceous material and smelted in a blast furnace to obtain metallic tin.—A. R. P.

Smelting and electrolysing process. R. Rodrian, Assr. to Rodrian Electro-Metallurgical Co., Inc. U.S.P. 1,426,507, 22.8.22. Appl., 3.3.22.

A CHARGE of metalliferous material is melted above a bath of molten metal and an electric current is passed through the mass, the molten metal acting as cathode and a carbon rod as anode.—A. R. P.

Brass; Method of making ——. W. R. Webster. U.S.P. 1,426,623, 22.8.22. Appl., 31.3.20.

A CURVE is constructed showing the variation in the value of a physical characteristic of brass with differing proportions of zinc and copper. The composition of a mixture of scrap brass that is being melted is then determined by determining the value of the same characteristic on a test drawn from the furnace and reading the corresponding copper content on the curve. Sufficient copper or zinc may then be added to the furnace charge to bring the mixture to any desired composition.—A. R. P.

Metals [e.g. aluminium]; Recovery of —— from silicates. F. M. McClenahan. U.S.P. 1,426,890—1, 22.8.22. Appl., (A) 22.12.20, (B) 7.12.21.

(A) As a step in the recovery of metals from silicates the latter are decomposed by an excess of ammonium fluoride solution. (B) Aluminium hydroxide is recovered from a mixture of aluminium and ammonium fluorides by heating in the presence of water and removing the evolved vapours.
—A. R. P.

Metals and alloys; Process for briquetting turnings and scrap of ——. R. Walter. G.P. 352,684, 5.12.20. Addn. to 337,296 (J., 1921, 582 A).

IN the process described in the chief patent reducing substances are added to the scrap or briquettes when they contain metallic oxides, so that it is possible to employ oxidised scrap which could otherwise not be used.—A. J. H.

Ores; Process for the treatment of —— previous to blast sintering. Metallbank und Metallurgische Ges. A.-G. G.P. 353,867, 12.2.14. Addn. to 340,583 (J., 1922, 20 A).

The ore is treated with a fine spray of water in the form of a mist instead of with steam, so as to reduce the cost of the process.—A. R. P.

Magnesium and its alloys; Process for colouring ——. Chem. Fabr. Griesheim-Elektron. G.P. 354,281, 30.8.19.

The metal is treated with a solution of chromic acid containing salts of the heavy metals and small quantities of other acids. To obtain stable colours the articles, after removal from the pickling bath, are washed in boiling water and then heated in an air-bath to 100°—150° C. The shade of colour obtained depends on the nature of the heavy metal (copper, manganese, zinc, chromium, iron or cobalt) in the pickling bath. Black tones are obtained by using a larger amount of acid and no heavy metal salt. —A. R. P.

Metallic articles; Process for coating —— with a chemically inactive [acid-resisting] substance. W. Roth. G.P. 354,693, 1.11.21.

The articles are coated with molten silver bromide. A second layer may be provided if desired. The process is suitable for coating metallic articles which are to be used for electrochemical purposes in acid media.—A. R. P.

Antimony-lead alloys [; Process for the preparation of hard acid-resisting ——]. Soc. Thoumyre Fils. G.P. 354,978, 19.6.21.

Antimony is heated with a ferro-alloy, such as ferro-manganese, ferro-aluminium, ferro-nickel, ferro-vanadium, or ferro-tungsten in a finely divided form until the mass melts, whereupon the requisite quantity of molten lead is added. The resulting alloys are as hard as iron and very resistant to acids; they are suitable for the manufacture of cocks, pumps, vessels, and the like for acid liquids.—A. R. P.

Zirconium and similar metals, e.g., titanium, cerium, thorium, and the like; Process for treatment of materials containing ——. G. Siebert, Platin-Affinerie und Schmelze, and E. Korten. G.P. 355,485, 14.12.20.

The material is treated with halogens at a high temperature in presence of reducing agents, *e.g.*, carbon. A vertical electric furnace is used, having a funnel-shaped lower portion through which one of the electrodes is introduced. The walls of the furnace are protected by a stamped lining of the reaction mixture. At the beginning the reaction is effected under the influence of an arc struck between the electrodes, but subsequently the ends of the electrodes are pushed down into the reaction mixture or covered with a further quantity of the latter so that the charge acts as a resistance heater. Gaseous reacting substances are introduced into the furnace through one or more of the electrodes. —H. R. D.

Phosphate slags; Utilisation of basic ——. H. Nagell. G.P. 356,225, 14.5.18.

Vanadium compounds may be recovered from basic phosphate slags by heating a slightly acid solution of the slags.—A. B. S.

Manganese steel; Method of recovering ——. W. G. Nichols, Assr. to American Manganese Steel Co. Reissue 15,434, 22.8.22, of U.S.P. 1,291,656, 14.1.19. Appl., 17.12.21.

See J., 1919, 261 A.

Metal constituents of metalliferous materials; Process for dissolving out or recovering the ——. H. Bardt. E.P. 184,402, 10.10.21.

See U.S.P. 1,423,069 of 1922; J., 1922, 716 A.

Tin deposits; Process of producing dense and firmly-adhering ——. M. Schlötter. U.S.P. 1,426,678, 22.8.22. Appl., 21.1.20.

See E.P. 148,334 of 1920; J., 1921, 853 A.

Coating metal objects with a layer of another metal; Process for ——. O. Stalhane and O. O. Kring. U.S.P. 1,426,683, 22.8.22. Appl., 29.4.20.

See E.P. 167,262 of 1920; J., 1921, 703 A.

Ores containing zinc, cadmium, and copper; Electrolytic treatment of ——. D. Avery, R. H. Stevens, and R. T. D. Williams, Assrs. to Electrolytic Zinc Co. of Australasia Proprietary, Ltd. U.S.P. 1,426,703, 22.8.22. Appl., 16.3.20.

See E.P. 141,688 of 1920; J., 1921, 589 A.

XI.—ELECTRO-CHEMISTRY.

Carbon-electrode industry; The technology of the ——. V. Baking and baking furnaces. C. L. Mantell. Chem. and Met. Eng., 1922, 27, 312—318. (*Cf.* J., 1922, 718 A.)

Furnaces for baking "green" carbon electrodes may be either electrically heated, the electrodes themselves acting as resistors, or gas-fired. In the electric furnaces the electrodes are packed in between two permanent end walls connected to the electric supply, and side walls of loose bricks are built up and strengthened with tie rods. The space between the electrodes is filled with crushed petroleum coke, and two cores are provided to start the process. Current is supplied at 30—60 volts, 25 cycles, and as the cores heat up, the volatile matter in the carbons is gradually distilled off until eventually they become sufficiently conducting to carry the bulk of the current. The baking process occupies 12—20 days, and a further period of 20 days is required for cooling; the maximum temperature attained varies from 1100° to 1300° C., those portions nearest the cores being at the highest temperature. Graphitising furnaces are constructed in a similar manner, but are operated at much higher temperatures (2000° C.), and the baking takes only 3—6 days. Gas-fired baking furnaces generally consist of rectangular pits for the carbon surrounded on both sides and at the bottom by heating flues; the pits form a rectangular "ring" round a central gas main, and the waste gas flues are disposed round the outside of the furnace. Each furnace is divided into a number of sections, each of which is independent of the others, so that part of the furnace is being loaded while other parts are heating or cooling. Each section is first heated with waste flue gases to about 500° C. (120 hrs.), then with fresh gas to about 1050° C. (75 hrs.), after which it is allowed to cool. All operations are controlled by thermocouple observations. At the present time gas-fired furnaces are gradually replacing electric ones, as the former are not only cheaper to run but are far more easy to control, and also allow of the recovery of the volatile by-products evolved by the binder on coking. The heat economy of the gas-fired furnace is much greater than that of the electric furnace owing to regenerative working, but the life of the latter is four times that of the former. The electrodes from the electric furnace are more difficult to clean, and the packing dust is more difficult to grind for re-use.—A. R. P.

Carbon-electrode industry; Technology of the ——. VI. Cleaning, testing, machinery and shipping. C. L. Mantell. Chem. and Met. Eng., 1922, **27**, 353—359.

Carbon electrodes, after baking, are cleaned either by tumbling in steel tumbling barrels or by brushing, followed, if necessary, by grinding on emery wheels; they are then tested for resistivity by means of a suitable ohmmeter, and for apparent specific gravity by weighing and measuring. The resistivity is directly proportional to the proportion of volatile matter and inversely proportional to the real density between 1·98 and 1·88. The cleaned carbons are inspected for faults, and all cracked and blistered rods are returned to the grinding process. A good electrode should have an apparent density above 1·54, not more than 2·5% of ash, a high electrical conductivity, slow rate of oxidation, and great mechanical strength, combined with a good shape, accurate dimensions, and low heat conductivity. The physical properties of various electrodes are compared, and a complete flow-sheet of the process of manufacture is given.—A. R. P.

Nickel; Use of granulated —— for electric heating. O. Dony-Hénault. Bull. Acad. roy. Belg., 1922, **8**, 67—70. Chem. Zentr., 1922, **93**, IV., 418.

"Mond" nickel is suitable for use in place of steel in the construction of resistances used in electric furnaces. The thin black layer of oxide with which the nickel becomes coated when heated is a conductor when cold. The following results give the respective percentage increases of weight due to oxidation when steel and "Mond" nickel spheres of the same size were maintained for long periods at a red or white heat. Percentage increase of weight after 20 hours at 600°—700° C., steel 2·77%, nickel 0·113%; after a further 17 hours at 1000° C., steel 9·40%, nickel 0·73%.—J. S. G. T.

Patents.

Electric battery. R. C. Benner and H. F. French, Assrs. to National Carbon Co. U.S.P. 1,425,573, 15.8.22. Appl., 16.1.19.

Mercury and lead material are associated with the active surface of a negative zinc electrode.—H. H.

Electrolytic cell. A. V. Davis. U.S.P. 1,425,752, 15.8.22. Appl., 7.6.21.

An anode and a cathode are spaced to provide between them an anode chamber opening freely into the cell at its upper and lower ends. Means are provided for supplying an electrolyte solution to the cell and for automatically maintaining its level above the upper end of the chamber as electrolytic action takes place, thus producing a thermosiphonic circulation of the electrolyte upwards in the chamber and downwards in the cell.—H. H.

Electric arc furnaces; Apparatus for the treatment of gases in ——. P. Real. G.P. 354,527, 16.7.20.

In a furnace with electrodes in the form of rotating discs, the latter are fitted with wings which communicate the rotary motion to the entering gases. The rapid burning away of the electrodes is thus avoided.—C. I.

Gases; Process of treating —— in the electric flame arc. P. Real. G.P. 356,413, 15.1.21.

Rotating disc-electrodes provided with wind vanes are arranged in star formation in vertical planes disposed radially about a common axis coinciding with the direction in which the gas to be treated is fed to the arc.—J. S. G. T.

Carbon electrodes; Process of increasing the durability and conductivity of ——. A. Bergström. G.P. 354,773, 30.4.19.

Carbon electrodes are impregnated with a mixture of solutions of a metallic salt and of carbon compounds and then heated to a high temperature. In this manner the reduction of the metallic salt to metal is not effected at the expense of the electrode.—J. S. G. T.

Electrolytic tanks with diaphragm cells; Arrangement in ——. G. Haglund. U.S.P. 1,426,071, 15.8.22. Appl., 10.9.20.

See E.P. 151,260 of 1920; J., 1921, 121 A.

XII.—FATS; OILS; WAXES.

Oil seeds; Certain tropical ——. E. R. Bolton and D. G. Hewer. Analyst, 1922, **47**, 282—284.

The following seeds are described and the percentage of shell, kernel, and of oil in the kernel are given, together with full analytical characters of the oils obtained from them:—Bacury (*Platonia insignis*) kernels, Andirobinha or Mapia seeds, Bey beans (*Baillonella sp.*), Parinarium seeds, and the seeds of *Theobroma grandifolia* and *bicolor*.—H. C. R.

Soya bean oil; Composition of ——. W. B. Smith. J. Ind. Eng. Chem., 1922, **14**, 530—531.

The composition of the acids of soya bean oil having an iodine value of 134 (calculated as percentages of the original oil) is approximately as follows:—Linolenic acid, 2—3; linolic acid, 55—57; oleic acid, 26—27; saturated fatty acids, 9—10%.—W. P. S.

Beef bone fat and neat's foot oil. H. Eckart. Z. Unters. Nahr. Genussm., 1922, **44**, 1—29.

The bones are first boiled in open kettles, whereby the adhering flesh is removed and the best quality fat is obtained, but the cartilage is practically unchanged. The bones are then transferred to digesters and treated with hot water and steam at 0·5—1·5 atm. pressure for 4—6 hrs. The fat thus obtained from fresh bones is of a light yellow colour and faint aromatic odour and can be used without refining as an edible fat, the free fatty acids not amounting to more than 1·5% (as oleic acid). Details of the yields obtained in practice are given, the average yield of fat from bones being 12·6% and that of oil from the hoofs being 9·3%. A table of analytical characters of bone fats, marrow fats, kidney fats, and neat's foot oils as obtained by the author from a well-nourished animal and as found in commerce is given. The rate of increase in free fatty acids shown by bone fat and neat's foot oil on storage depends on the conditions of storage and is much more rapid if the sample is exposed to the action of light and air than if it is stored in the dark and sealed up. In the case of the solid fat exposed to light and air an autocatalytic hydrolysis appears to take place, while in the case of the oil the hydrolysis appears to be a monomolecular reaction. Measurement of the surface tension of neat's foot oils by the drop-pipette method gave values varying from 26·7 to 29·7 dynes per sq. cm. at 50° C. The mixed ethyl esters of the fatty acids from bone fat were prepared and their analytical constants recorded. The compositions of beef bone fat and neat's foot oil are as follows:—Stearic acid 19—21%, 2—3%; palmitic acid, 20—21%, 17—18%; oleic acid, 53—59%, 74·5—76·5%; glycerol, 5—10% in both ases; unsaponifiable matter, about 0·5% and 0·1—5% respectively. The presence of cholesterol in he unsaponifiable matter in each case was conrmed. Tristearin was definitely identified as a onstituent of beef bone fat.—H. C. R.

Hardened fats; Ability of —— to hold water in suspension. K. Brauer. Chem.-Zeit., 1922, **46**, 793—794.

AMPLES of hardened and other fats used in the manufacture of margarine were melted and agiated with water and the percentage of water in he emulsion determined both before and after the emoval of as much as possible by pressing. The folowing figures were obtained: Hardened whale oil, 9%, 23%; hardened soya bean oil, 25%, 7%; hardned herring oil, 18·6%, 9·9%; hardened linseed oil, 6%, 5·8%; coconut oil, 6·4%, 3·6%; tallow, 15%, 0·8%. The striking ability of hardened whale oil o take up water and retain it even after pressing s suggested as a means of distinguishing between t and other hard fats.—H. C. R.

Twitchell's reagent; Constitution of ——. A. E. Sandelin. Annal. Acad. Scient. Fennicae, 1922, [A] **19.** (19 pages.) Chem. Zentr., 1922, **93**, IV., 508—509.

HYDROXYSTEARIC acid, hydroxystearosulphuric acid, and α- and β-naphthalenesulphonic acids possess no fat-hydrolysing properties, but a compound with feeble fat-hydrolysing properties is obtained when a mixture of hydroxystearosulphuric acid or hydroxystearic acid and α-naphthalenesulphonic acid is treated with sulphuric acid. By oxidising Twitchell's reagent with alkaline potassium permanganate, an acid was obtained the lead salt of which had the empirical formula, $C_{18}H_6O_{12}Pb_3$. Analysis indicated a tricarboxybenzene. The free acid consisted of prisms of m.p. 189°—190° C., soluble in ether, alcohol, and acetone, but only slightly soluble in light petroleum spirit, carbon tetrachloride, and chloroform. The sodium and potassium salts are easily soluble, the barium salt slightly soluble in water. The silver salt is soluble in hot water. Analysis of the free acid gave the formula $C_9H_6O_6$, and it is in all probability hemimellitic acid. The difficultly soluble barium salt of another acid, benzene-1.2-dicarboxy-4-sulphonic acid, was also isolated. The formation of these two acids leads to the conclusion that Twitchell's reagent is formed by combination of the naphthalene with the double bond of the oleic acid and sulphonation of the addition product, and that it has the constitution $C_{18}H_{35}O_2C_{10}H_6SO_3H$. In all probability fat-hydrolysing agents prepared from naphthalene and ricinoleic acid, castor oil or their hydrogenation products are of analogous constitution. The "Kontakt" fat-hydrolyser is, on the other hand, of different constitution, for here the sulphonic acid of high molecular weight contains no carboxyl groups.—H. C. R.

Fat-hydrolysing catalysts. A. E. Sandelin. Annal. Acad. Scient. Fennicae, 1922, [A] **19.** (13 pages.) Chem. Zentr., 1922, **93**, IV., 509.

THE reagents prepared from petroleum (Happach) and naphtha contain no carboxyl groups. All these reagents have the following properties in common. They are of high molecular weight, are sulphonic acids, easily soluble in water and can be precipitated by the addition of acids or sodium chloride solution; they are easily soluble in alcohol and slightly soluble in ether. Their aqueous solutions foam strongly, as also do solutions of their alkali salts, which are soluble in alcohol. Their alkaline-earth and metallic salts are amorphous and insoluble in water, but are often soluble in alcohol. Their action in the hydrolysis of fats is due first to their action as emulsifiers of fat with water and secondly to the fact that they are strong acids and as such accelerate the hydrolysis. Their action is intensified by the addition of sulphuric acid. Many sulphonic acids of high molecular weight have been prepared, such as those from oleic acid with toluene, cymene, terpenes, alcohols, and benzene, thymol, or naphthalene, and their fat-hydrolysing action has been tested. All had considerable effect as fat-hydrolysers, with the exception of those prepared from oleic acid and toluene or cymene. The failure of those is no doubt due to the decomposition of the sulphonic acids by boiling water.—H. C. R.

Unsaponified fat in soap; Determination of ——. O. Hagen. Seifensieder-Zeit., 1922, 49, 359—361. Chem. Zentr., 1922, **93**, IV., 330.

IF petroleum spirit is used in this determination very troublesome emulsions are usually met with, while with ether, although with care emulsions can be avoided, considerable amounts of soap are dissolved. The following method is suggested as overcoming the difficulties. The soap is cut into shavings and completely dried at 100° C. It is then mixed with about 5 times its weight of sand and extracted with petroleum spirit (b.p. below 60° C.) in a Dittmar and Vierth's rapid extractor. The extraction is complete in 1½—2 hrs. and the extract is evaporated to dryness. The determination can be completed in a day.—H. C. R.

PATENTS.

Oils and fats; Process for purification of ——. N. Goslings. E.P. 167,462–3, 22.6.21. Conv., 3.8.20.

THE free fatty acids are neutralised with alkaline-earth or metallic hydroxides and other bases which form insoluble soaps with the fatty acids, a soluble salt being added to the bases in such quantity as is necessary nearly to saturate the water used for dissolving or suspending the bases. The quantity of neutral fat carried down with the soap is by this means reduced to 5—12%. In the case of liquid fats and oils the soap produced is hardened by the incorporation of a small quantity of solid fatty acids with the oil before neutralising it.—H. C. R.

Cottonseed; Method of delinting ——. L. G. Polhamus. U.S.P. 1,425,688, 15.8.22. Appl., 19.4.22.

THE cotton seed is exposed to the action of gaseous hydrochloric acid for about one hour to render the lint extremely brittle, and is then agitated to remove the lint. The seed is subsequently exposed to the action of gaseous ammonia.—H. C. R.

Fish oil and the like; Apparatus for treating —— with ozone. J. C. W. Stanley, Assr. to The Title Guarantee and Trust Co. U.S.P. 1,425,803, 15.8.22. Appl. 21.3.21.

THE apparatus comprises a chamber containing in its upper portion an oil receiver with a perforated bottom. A reservoir is provided for receiving the oil discharged from a chamber and is connected with it by a pipe; a pump is arranged to circulate oil through the chamber. There are also means for passing air through an ozoniser and then through the chamber, and for passing heated air through the chamber.—H. C. R.

Catalysts; Non-pyrophoric —— and process for effecting reactions [hydrogenation] therewith. N. Sulzberger. U.S.P. 1,426,517, 22.8.22. Appl., 11.9.16.

The catalyst comprises a black, non-pyrophoric, magnetic, catalytically active reduction product of a reducible nickel compound, reduced by a wet process and in the presence of a metal of the platinum group. The product contains nickel and the metal of the platinum group in an intimate state of combination.—H. C. R.

Hydrogenation; Catalyst for —— and the preparation thereof. C. Ellis. U.S.P. 1,426,629, 22.8.22. Appl., 23.12.13.

A nickel compound capable of being converted into a catalyst and an insoluble sulphate capable of acting as an accelerator are precipitated together. —H. C. R.

Hydrogenating catalyst. G. Teichner. U.S.P. 1,427,037, 22.8.22. Appl., 29.9.20.

A precipitated non-coherent, loose, amorphous compound of nickel is reduced in a dry state at such a low temperature that cohesion or slagging of the particles is avoided, while the interior of each particle is left unreduced.—H. C. R.

Catalyst [for hydrogenation]; Process of manufacturing ——. A. W. Arldt. G.P. 356,614, 23.4.16.

The metals or reducible metallic compounds employed to produce the catalyst are impregnated with a substance such as sugar or fatty oil, which is then carbonised by means of concentrated sulphuric acid at ordinary temperature. A similar treatment with sulphuric acid may be employed for the revivification of spent catalysts poisoned with organic residues, *e.g.*, oil.—J. S. G. T.

Oils and fats; Method of and apparatus for crystallising ——. H. H. Doering. U.S.P. 1,426,555, 22.8.22. Appl., 16.2.20.

A stream of hot oil is introduced at the bottom of a body of cold water and a jet of compressed air discharged adjacent to the point at which the oil is introduced, so that the oil is broken up into small particles prior to solidifying into crystals.—H. C. R.

Soaps; Process for the electrolytic production of ——. A. Sandreczki. G.P. 354,234, 3.2.20.

The electrolyte is a mixture of fat and salt solution. It is caused to stream past the cathode by heating it or by other means. The two electrodes are in the form of hollow cylinders with a common axis and separated by a diaphragm. Within the inner cylinder is a stirring device which causes the liquid inside this electrode to be projected over the edge into the annular space between the two electrodes, from which space it passes under the inner electrode and is again carried up by the stirring device, so that it is kept in circulation during the electrolysis.—H. C. R.

Detergent with disinfecting properties. E. Chamberlin. E.P. 184,248, 3.5.21.

A detergent and disinfectant solution is prepared by boiling together a mixture in water of sodium carbonate and potassium permanganate with animal charcoal and filtering the mixture. —H. C. R.

Lime sludge; Process for completely removing the soap from ——. P. Krebitz. G.P. 355,492, 22.4.20.

Before treating the lime-sludge with water in the usual manner, coconut or palm-kernel oil soap is added to the extent of at least 25% of the total soap content of the sludge. Alternatively resin soap may be added to the lime-sludge to the extent of at least 20% of its total soap content. If the original mixture of fats consists only of animal fats, hardened oils, olive or palm oils, or any fats or oils of which the alkali soaps are strongly hydrolysed on dilution with water, it is very difficult to remove the soap from the lime-sludge, which can neither be filtered nor centrifuged. By following this process any mixture of fats can be treated according to Krebitz's process (J., 1904, 490; 1906, 188, 434).—H. C. R.

Sulphurised oils. G.P. 354,172. *See* XIV.

Converting organic acids into esters. E.P. 183,897. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Carbon black—its manufacture, properties and uses. R. O. Neal and G. St. J. Perrott. U.S. Bureau of Mines, Bull. 192, 1922. 95 pp.

Carbon black, in contradistinction to lampblack, vegetable black, etc., is obtained by direct contact of a flame of natural gas upon a depositing surface under conditions of incomplete combustion. Attempts to obtain carbon black by thermal decomposition or cracking processes have hitherto not been commercially successful on account of the relative inferiority of the products obtained, whilst processes purporting to increase the yield of carbon by effecting combustion in the presence of chlorine have been found to occasion undue depreciation of the apparatus involved. The production of carbon black from coal gas or other artificially made combustible gas, although claimed to yield a finer and blacker product, has not been undertaken commercially owing to the prohibitive price of the raw material in comparison with natural gas, which latter yields a handsome profit in spite of the low efficiency of the present combustion processes, viz., 2·5% recovery. The methods of manufacture of carbon black from natural gas differ mainly in the size and shape of the surface upon which the carbon is collected and the rate of travel of the moving parts of the apparatus. Generally speaking, the combustion plant consists essentially of a combustion building furnished with means for regulating air supply and ventilation at both inlet and outlet, and provided with burners adapted to play their flames upon collecting surfaces. The latter vary in design as the names of the several processes denote, and in decreasing order of output comprise (1) the channel process, (2) the small rotating disc process, (3) the large plate process, and (4) the roller process. In the channel process the flames from a number of fishtail-mouthed steatite-tipped burners are caused to impinge on to the under surface of travelling iron channel girders arranged horizontally side by side along the length of the combustion chambers, the deposited carbon being detached by stationary scrapers. A typical combustion building would contain about 38,400 burners. In the small disc process, the collecting surfaces consist of rotating discs of cast iron 36—42 in. in diameter, on the under side of which the flames impinge. The plates used in the large plate or Cabot process have a diameter of 24 ft., the plates being made of 48 segments. The plates are fitted with ventilator holes to allow the products of combustion to escape and maintain a draught. The rotating plates are furnished with scrapers and the operation is somewhat similar to that of the other processes, but owing to relative lightness of the supporting construction and slow movement of rotation of the plates, very little power is consumed in operation. In the roller or rotating cylinder process the flames from round burners impinge on horizontally supported rollers or cylinders 3—8 ft. in length and 8¼ in. outside diameter, disposed transversely to the length of the building. The scrapers are in contact with the roller at or near the top, whence the deposited carbon falls into a trough-shaped hopper in the bottom of the combustion chamber. A typical building contains 10,000 burners and 196 to 288 rollers. The temperature of combustion and the careful regulation of the air supply play an important part in determining the yield and nature of the black obtained, an insufficiency of air furnishing a carbon black containing absorbed intermediate products of incomplete combustion appearing as "volatile matter" on analysis. Such a product yields a "longer" black of lower fixed carbon content, a property in particular demand for certain purposes. The paper concludes with analyses of typical blacks of proprietary makes and specifications of material suitable for use in the several industries of printing ink, rubber, etc., together with a bibliography of the patent and technical literature relating to carbon black manufacture.—A. de W.

Shellac; Solubility of —— in alkalis or alkaline salts. H. Wolff. Farben-Zeit., 1922, **27**, 3130—3131.

THE solution of shellac in solutions of sodium carbonate, borax, etc., is not due to chemical combination of the base with the free aleuritic acid or the neutral saponifiable compound present in the shellac in amount corresponding to its ester value, since the resin dissolves in slightly warm sodium carbonate solution without a corresponding evolution of carbon dioxide. Furthermore, when shellac dissolved in just a sufficient amount of sodium carbonate solution is completely dried, the residue is no longer soluble in water but merely swells, the degree of swelling diminishing with each successive drying operation, as with a typical colloid. The solution process is therefore in the nature of a peptisation. The author claims to have obtained a water-peptisable residue by evaporation of the sol obtained by pouring an alcoholic solution of shellac into water; the residue, however, proved to be insoluble in alcohol until its solubility in water was lost by ageing. The loss of alcohol-solubility in bleached shellac is attributed to the coagulating effect of hydrogen-ions from the precipitation by acid, the maintenance of solubility by storage under water being in consequence due to a diminution of hydrogen-ion concentration.—A. de W.

Resins; Relation between the constitution of chemical compounds and their capacity to form ——. II. New method for production of synthetic resins. W. Herzog and J. Kreidl. Z. angew. Chem., 1922, **35**, 465—466. (*Cf.* J., 1921, 478 A.)

WHEN heated at 180° C. in a stream of carbon dioxide dibenzylideneacetone is gradually converted into a polymeric resinous compound, which melts between 85° and 95° C. and is soluble in ether, benzene, and turpentine. Analogous compounds, *e.g.*, dianisylideneacetone, dicinnamylideneacetone, benzylidenecinnamylideneacetone, difurylideneacetone and dipiperonylideneacetone give similar products. The capacity to polymerise in this way with formation of resins is attributed to the CH:CH·CO grouping, which is regarded as "resinophoric"; the additional presence of ethylenic linkages is favourable to the change. The grouping N:C:N has previously been shown to possess resinophoric character.—D. F. T.

Red lead and lead sesquioxide. Glasstone. *See* VII.

PATENTS.

Red oxide of iron; Manufacture of ——. D. Tyrer. E.P. 183,323, 8.6.21.

FERRIC oxide of good red colour can be obtained by exposing dry granular ferrous chloride (*e.g.*, from galvaniser's waste) in thin layers to the action of a mixture of steam and air heated to 250°—300° C.; the best mixture is obtained by passing air at ordinary temperature through water at 60° C. The condensed liquid obtained by cooling the mixture of air and excess steam should not attain a greater concentration than 30 g. of hydrochloric acid per 100 c.c. The action may be accelerated and the colour of the product enhanced by the addition to the ferrous chloride of a considerable proportion of ferric hydroxide or ferrous carbonate or of 0·1—1% of salts of copper, magnesium, tin, sodium or potassium.—D. F. T.

Inks and other pigmenting and like compositions. A de Waele. E.P. 183,513, 19.3.21.

THE vehicle for the colouring matter consists of an emulsion or emulsoid of which the component materials, *e.g.*, Yorkshire grease (from the waste liquor of wool washing) and water, possess "yield values" (*cf.* Bingham and Green, J., 1920, 495 A) materially lower than the yield value of the vehicle as a whole. The oily material normally forming the more viscous constituent may be mixed with a mineral oil or other organic solvent. With a vehicle of Yorkshire grease and water the latter may amount to 50—250% of the former, and the pigment may be a water-soluble dyestuff, such as Nigrosine.—D. F. T.

Pigments; Process of preparing —— from titanium compounds contaminated with sulphuric acid. G. Carteret and M. Devaux. E.P. 184,132, 27.7.21.

TITANIC oxide which has been washed with sulphuric acid, or other titanium compound contaminated with sulphuric acid is treated with an alkaline-earth chloride in solution, the free hydrochloric acid formed being eliminated by washing with milk of lime or milk of baryta and the titanic oxide finally dried.—A. de W.

Pigment and method of producing same. P. Fireman, Assr. to Magnetic Pigment Co. U.S.P. 1,424,635, 1.8.22. Appl., 31.5.19.

PRECIPITATED ferrous hydroxide is oxidised whilst suspended in its mother liquor, the oxidation being controlled by limiting the temperature during the early stages of oxidation to a point below that at which black oxides form.—D. F. T.

Pigment and pigment composition. K. B. Lamb, Assr. to The American Cotton Oil Co. U.S.P. 1,424,729, 1.8.22. Appl., 27.4.21.

AN intensely black pigment is produced by heating spent fuller's earth, with stirring, until the oil present is ignited and is finally consumed.
—D. F. T.

Paint composition. K. B. Lamb, Assr. to The American Cotton Oil Co. U.S.P. 1,424,414, 1.8.22. Appl., 2.2.22.

THE black pigment obtained by carbonising spent fuller's earth under suitable conditions is mixed with other black pigments and a drier and incorporated with a paint vehicle.—D. J. N.

Condensation products from phenols and aldehydes; Manufacture of ——, Bakelite-Ges. m.b.H., and R. Hessen. E.P. 159,461, 15.2.21. Conv. 1.3.20.

BY treating the primary product obtained by the condensation of formaldehyde and a phenol in the presence of a basic condensation agent, with sufficient acid or acid-forming substance approximately to neutralise the base, it is possible to produce "resoles," *i.e.*, resins which form infusible masses ("resites") when heated. Using a higher proportion of acid, albeit insufficient to effect direct conversion into "resites," a "novolak," *i.e.*, a resin which cannot be converted into an infusible mass by heat, is obtainable.—D. F. T.

Oil and varnish colours miscible with water. F. Günter. E.P. 183,177, 7.3.21.

A watery paste of the colouring material is emulsified together with binding agents (*e.g.*, drying oils) insoluble in water, in the presence of volatile stabilising agents, such as alcohol, pyridine, acetone, or naphthenic acid, and which are soluble both in water and in the binding agent. As an alternative, alkali salts of the fatty acids and of resin acids may be employed as stabilisers, in which case an element such as sulphur, phosphorus, or selenium, capable of forming an acid by slow oxidation, is added to the emulsion.—D. F. T.

Resins; Preparation of synthetic ——. D. G. Anderson and R. Maclaurin. E.P. 183,629, 17.5.21.

Synthetic resins are produced by the condensation of formaldehyde with the monohydric phenolic substances, boiling between 230° and 320° C., present in tars obtained by the low temperature distillation of coal.—D. F. T.

Rosin; Means for extracting crude spirits and —— from yellow and green pine stumps. J. M. Jordon. U.S.P. 1,424,248, 1.8.22. Appl., 10.1.21.

The wood is supported inside a vertical cylindrical chamber which is surrounded by a steam and water space. The water in the annular jacket is heated by means of a fire-box constructed inside the jacket. The extracted turpentine collects in the funnel-shaped bottom, which is provided with an outlet pipe.—D. F. T.

Resinous condensation products of aldehydes and phenols; Preparation of ——. A. Koch. G.P. 354,697, 13.4.20.

The condensation product of a phenol and an aldehyde is treated, during or after its formation, with hydrogen, preferably at elevated temperatures and under pressure, in the presence of any of the usual metallic catalysts, *e.g.*, reduced nickel or colloidal nickel, platinum, or palladium, in the presence of a protective colloid. For example, hydrogen is passed at 80° C. and under 3 atm. pressure through the anhydrous liquid condensation product obtained from phenol and a 40% aqueous solution of formaldehyde, in the presence of ammonia, until no further absorption of gas occurs, finely divided nickel being used as a catalyst. The product is filtered, washed, and concentrated. On heating it becomes hard, and is then soluble in alcohol, acetone, and caustic soda. It is odourless and has a higher melting point than that of the resin obtained under the same conditions without hydrogenation. Similar products may be obtained by passing hydrogen through a solution of resins (obtained from aldehydes and phenols) in suitable organic solvents not containing double linkings, *e.g.*, alcohol, in the presence of finely divided nickel.—A. R. P.

Resinous products from phenols methylated in the nucleus; Process for preparing ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 355,173, 3.2.20, and 355,174, 24.8.20.

Cresol, chlorocresol, or higher homologues are treated with chlorine at temperatures above 100° C. until nearly free from substances volatile in steam, and the residue, on cooling, solidifies to a hard amorphous mass. Alternatively the cresol or the like may be saturated with chlorine at ordinary or slightly higher temperatures, and the resulting product heated above 100° C., under reduced pressure if necessary. The products, according to the chlorine content, are soluble in alcohol, acetone, ether, and alkalis. When the chlorine content is high the products are soluble only in benzene hydrocarbons. They can be used for the preparation of dark or black varnishes and have a strong bactericidal action.—J. B. F.

Resinous condensation products of phenols; Preparation of ——. Dynamit A.-G. vorm. A. Nobel und Co. G.P. 355,389, 4.1.20.

Halogenated aromatic hydrocarbons of the type $R.CHX_2$ are heated with phenols in the presence of a small quantity of a metal halide. Thus, benzal chloride is heated with either phenol, in the presence of zinc chloride at 50°—100° C., or with *m*-cresol, in the presence of aluminium chloride at 70° C., until hydrogen chloride is no longer evolved, and the excess phenol or cresol is removed by steam distillation. An odourless, light-coloured resin, which is soluble in caustic alkalis, methyl alcohol, ethyl alcohol, benzene, and chloroform, is thus obtained. Similar products are obtained from homologues of benzal chloride or from derivatives containing halogen atoms in the nucleus.—A. R. P.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

[Rubber] latex; Application of hydrogen sulphide and sulphur dioxide gases direct to ——. H. P. Stevens. Bull. Rubber Growers' Assoc, 1922, 4, 386—387.

It is not possible to vulcanise the rubber globules of latex with hydrogen sulphide and sulphur dioxide. The gases under these conditions merely dissolve in the aqueous serum, and there react, producing molecular sulphur.—D. F. T.

Patents.

Vulcanisation of rubber and apparatus for use therein. B. Lambert. E.P. 183,590, 27.4.21.

Vulcanisation is effected in a medium consisting of the eutectic alloy of tin (25 pts.), lead (16 pts.), and cadmium (9 pts.), which melts at 145° C. A sufficient proportion of the alloy to maintain the temperature during the required period of solidification is melted by an immersed, insulated, electrically heated wire. In order to shorten the time of vulcanisation, an alloy containing the metals in the proportions 57:21:22 may be employed, having a solidification range of 153°—145° C.—D. F. T.

Caoutchouc and caoutchouc-like substances and compounds thereof or compositions comprising same; Fireproofing natural and artificial ——. H. Frood and H. P. Alger. E.P. 183,922, 30.4.21.

Rubber materials, particularly floor coverings containing rubber, together with inorganic or organic fibrous fillers (the latter themselves also preferably being treated with fireproofing agents), are rendered less inflammable by the incorporation of casein and hydrated aluminium oxide, together with a small proportion of antimony trichloride.
—D. F. T.

Rubber; Process of reclaiming ——. J. O. Navone. U.S.P. 1,424,668, 1.8.22. Appl., 24.1.20.

The rubber is dissolved from a rubber product in a hydrocarbon, the latter being subsequently removed by evaporation and the rubber precipitated in heated water.—D. F. T.

Plastic mass especially suited for use as a tyre-filler; Process for producing and using a ——. R. Gollert. G.P. (A) 303,924, 15.8.16, (B) 305,197, 30.1.17.

(A) Starch powder is mixed with "perglycerin" or "perkaglycerin" (*cf.* Neuberg and Reinfurth, J., 1920, 801 A) to a homogeneous paste, and if necessary with the aid of heat. The mixture is introduced into the tyre whilst fluid, and then submitted to further heating, *e.g.*, at 60° C. (B) A non-fluid mass, produced by mixing the preceding product with more starch, may be first introduced into the tyre, followed by a more fluid mass. After a suitable maturing period the filling material is subjected to heat.—D. F. T.

Sulphurised oils, particularly factice; Manufacture of ——. F. Balla, and Farbenfabr. vorm. F. Bayer und Co. G.P. 354,172, 10.12.20.

By treating oils with sulphur in the presence of a vulcanisation accelerator, products are obtained of increased hardness and free from residual sulphur. —D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Hide curing; Science of ——. G. D. McLaughlin and E. R. Theis. J. Amer. Leather Chem. Assoc., 1922, **17**, 376—399.

Hides are dehydrated by salting or immersion in a 25% brine solution. Of the three layers the adipose tissue is most dehydrated. The salt is absorbed by the hide during the process, and the greater the dehydration the greater the amount of absorbed salt. The epidermis does not absorb salt very readily, so that only the flesh side should be salted. If salting is delayed after the animal has been killed, the rate of diffusion of the salt into the hide is greatly reduced. The salt content of a hide containing blood which has been allowed to remain some time before curing is less than that of a similar hide from which the blood has been removed. The longer the delay between slaughtering and curing the greater the difference between the two. The diffusion of the salt is affected by the presence and condition of blood, by post-mortem changes, and by the composition of the salt. Hides should be washed and brined as soon as possible after flaying to secure a maximum absorption of salt in a minimum of time, to eliminate salt and iron stains, and to minimise the effect of post-mortem changes.—D. W.

Hide curing; Practice of heavy ——. G. D. McLaughlin and E. R. Theis. J. Amer. Leather Chem. Assoc., 1922, **17**, 399—404.

The authors have compared curing by "salting" and by "brining." When properly brined and tanned, the hides produce more leather, which is thicker, firmer, and has fewer salt and iron stains, than when the hides are salted. Brined stock requires special beam-house treatment, especially the use of "sharp" limes.—D. W.

Tannins and tanning extracts; Differentiation of ——. T. Körner and J. A. Bosshard. Ledertechn. Runds., 1922, **14**, 57—60, 65—66, 75—77. Chem. Zentr., 1922, **93**, IV., 289—290.

Quebracho tannin shows a higher carbon content than any other tanning material except cutch and gambier. Quebracho can be detected by dissolving a quantity of tanning extract in 10 parts of water, treating the solution with one-tenth of its weight of sodium chloride, filtering, extracting the filtrate with ethyl acetate, fractionally precipitating the ethyl acetate solution with alcohol, drying and analysing the last fraction. Pure quebracho extract in this way gives a carbon content of 60%, whilst with adulterated extracts lower values are obtained. Tannins can be separated and detected by fractional precipitation of the acetone solution of the acetylated tannin with alcohol. The acetylated tannins and the products obtained by their saponification lend themselves to differentiation. The acetylated tannins may be hydrolysed with 5 c.c. of hydrochloric acid (sp. gr. 1·19), cooled, treated with 25 c.c. of Wijs iodine solution, allowed to stand for 1 hour, diluted to 1 litre, and titrated with $N/10$ thiosulphate solution. The iodine absorbed by different tannins varies, but there is little variation for one and the same tannin.—D. W.

Tannin analysis; Contributions to —— *with special reference to gambier.* L. Pollak. Collegium, 1922, 125—133.

Various samples of Asahan gambier were analysed by the official shake method, by modifications of this method, using double and treble detannisations, a longer period of shaking, and a larger amount of hide powder, and by the filter bell method. The shake method with two and three detannisations gave a higher percentage of tans than the official shake method. There was no need to detannise three times. Pieces of sheep pelt were coloured in a known quantity of pine bark extract, and finished in a known amount of gambier liquor. The liquors were analysed by both filter bell and shake methods, before and after use, and the dry leather analysed. The discrepancies between the calculated amount of tannin in the leather and that actually found show that the official shake method gives less than the true tannin content and the filter bell method more.—D. W.

Tannin analysis. II. V. Kubelka and F. Berka. Collegium, 1922, 85—95, 143—155.

Results are given of numerous analyses of different extracts and tanning materials made by the official shake method, by detannising twice, and by the official shake method substituting dry chromed Freiburg hide powder for wet hide powder. The dry chromed powder has a higher absorptive power for materials which are not absorbed by the freshly chromed hide powder. The dry powder is used in the filter bell method, and that method yields better results than the shake method owing to the better absorptive power of the powder. The authors advocate the adoption of the filter bell method.—D. W.

Leather; Researches on ——. L. Jablonski. Collegium, 1922, 53—56, 96—97.

Portions from different parts of hides tanned with vegetable tanning materials in pits, partly in pits and partly in drums, and wholly in drums, and weighted, have been analysed for hide substance, specific gravity, water-soluble matter and fibrous structure. The results are shown graphically. Photomicrographs prove that the fibre bundles in the butt portions are thick and interwoven, whilst in the belly the bundles are very thin, and in some cases only separate fibres are present. No portion of a side is an average of the whole.—D. W.

Sole leather filled with sulphite-cellulose extract; Durability of ——. R. C. Bowker. U.S. Bureau of Standards, Tech. Paper No. 215. J. Franklin Inst., 1922, **194**, 241.

Sole leather filled with sulphite-cellulose extract is as durable as leather filled with chestnut wood and quebracho extracts.—D. W.

Keratin. I. A. Heiduschka and E. Komm. Z. physiol. Chem., 1922, **121**, 221—230.

Horn clippings were heated under a variety of conditions, for example, at atmospheric pressure, in a vacuum, in sealed vessels, and with water or ammonia in a vacuum. The temperature of incipient degradation varies with the time of heating and the conditions. Among the volatile products are ammonia, hydrogen sulphide, and other sulphur compounds.—H. K.

Ion concentration measurements. Keeler. *See* XXIII.

Patents.

Tanning hides; Process for ——. Chem. Fabr. Worms A.-G. E.P. 156,670, 6.1.21. Conv., 23.9.16.

Hides are tanned with the substances prepared according to E.P. 156,254 (J., 1922, 602 A), but treated with compounds (other than permanganates) of heavy metals, instead of with compounds of aluminium or chromium.—D. W.

Leathers; Treating and finishing ——. C. R. Reubig. E.P. 157,864, 10.1.21. Conv., 25.7.16.

Dressed or undressed leathers are treated for two hours with a solution of 8% of sodium thiosulphate and 5% of sodium sulphide to which has been added a caustic alkali, then with acids, and washed with water.—D. W.

Condensation products [tanning agents]; Method for the production of sulphonated ——. Elektrochem. Werke, H. Bosshard, and D. Strauss. E.P. 158,521, 10.1.21. Conv., 9.8.18.

Naphthalene or other polycyclic aromatic hydrocarbon, or carbazole, and sulphuric acid, or a sulphonic acid of the hydrocarbon or of carbazole, is condensed with glycollic acid by heating in the air or *in vacuo*.—D. W.

Hides and skins; Tanning arrangement for ——. M. Beretta. E.P. 159,215, 21.2.21. Conv., 20.2.20.

Hides and skins are tanned in an apparatus comprising one or more vessels divided longitudinally into two tanks, each vessel having at one end of the partition a port communicating with the two tanks, and provided with a sliding door, a filter chamber situated at the other end, and a propeller for circulating the liquor so that it can pass through the filter chamber if desired. The filter chamber may be provided with a sump to collect the solid matter. —D. W.

Tanning agents; Manufacture of ——. R. B. Croad, G. E. Knowles, and H. M. McArthur and Co., Ltd. E.P. 182,823, 3.1.21.

At least 2 mols. of an aromatic hydroxy compound is condensed in the open or under pressure with 1 mol. of formaldehyde, or an equivalent proportion of a compound yielding formaldehyde, in presence of an oxide, hydroxide, carbonate, or bicarbonate of an alkali or alkaline-earth metal, ammonia, or a salt of a strong base with a weak acid. The product is rendered soluble by sulphonation and partially neutralised.—D. W.

Tanning agents; Manufacture of ——. R. B. Croad, and H. M. McArthur and Co., Ltd. E.P. 182,824, 3.1.21.

At least 2 mols. of an aromatic hydroxy compound is condensed with 1 mol. of formaldehyde, or the equivalent proportion of a compound yielding formaldehyde, in presence of alkali or an alkaline salt, and the product is rendered soluble by sulphonating and further condensed with a suphonated aromatic compound and an aldehydic compound, or an aldehydic compound alone. The final product is partially neutralised.—D. W.

Tanning agent for the chrome tannage or dyeing of leather; Preparation of a ——. D. Burton and A. Glover. E.P. 184,360, 26.7.21.

A solution of sodium or potassium bichromate in water, after treatment with sulphuric or hydrochloric acid, is heated and then reduced by the addition of tea dust. Previous removal of the caffeine has little or no effect on the efficiency of the tea dust for this purpose.—D. F. T.

Chrome leather; Method for the neutralisation of ——. O. Röhm. G.P. 353,130, 2.12.19. Addn. to 352,285 (J., 1922, 722 A).

The leather is neutralised with sodium carbonate or other alkali or alkaline-earth carbonate, with the addition of formaldehyde or a formate, acetate, or lactate of an alkali or alkaline-earth metal; sulphites, thiosulphates, phosphites, arsenites, and arsenates of the alkali or alkaline-earth metals show a similar action to the salts of organic acids. For example, chrome-tanned pelts may be washed with water, allowed to stand in a bath containing a solution of sodium sulphite and calcium carbonate, until neutralised, then washed several times with water. —J. B. F.

Mineral tanned leather; Method for the neutralisation of ——. O. Röhm. G.P. 353,131, 2.12.19. Addn. to 352,285 (J., 1922, 722 A).

Iron- or aluminium-tanned leather is neutralised with alkali or alkaline-earth carbonates, together with formaldehyde or salts of lower fatty or hydroxy-fatty acids or of such weak inorganic acids, as carbonic acid. Thus an iron-tanned leather may be neutralised with calcium carbonate and sodium acetate, or sodium carbonate and sodium acetate, or an aluminium-tanned leather with sodium sulphite and sodium carbonate.—J. B. F.

Gas-impervious material [from animal membranes]; Method of making ——. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 184,012, 30.6.21.

A material impervious to gas and capable of retaining its flexibility when dry and at low temperatures is obtained by treating animal membrane, preferably the lining of the throat or bladder, with a hardening agent, such as Nigrosine, and a hygroscopic material having a freezing point below −50° F. (−46° C.), such as glycerin or ethyleneglycol. The membranes are first washed with dilute ammonia or similar detergent, dried while inflated, and preferably soaked for about 4 hrs. in a dilute (1%) solution of tannic or gallic acid; they are then agitated in a solution containing, for example, 30 pts. of glycerin, 5·5 pts. of ethyleneglycol, 2 pts. of Nigrosine, 70 pts. of water (by weight in each case), and, after removal of superfluous solution, are dried, preferably while mechanically working to increase their flexibility.—D. J. N.

Leather; Process for rendering —— *gas-tight.* A. Geiger and E. Brauer. G.P. 353,444, 14.2.18.

Leather is impregnated with halogenated aliphatic hydrocarbons of medium viscosity, and substances of high viscosity which will not crystallise out at low temperatures, *e.g.*, with a mixture of 70% of polymerised chlorinated spindle oil and 30% of coumarone resin.—D. W.

Tanning oils and fat-liquoring agents; Manufacture of —— *from hydroxy-fatty acids and phenol.* Gerb- u. Farbstoffwerke H. Renner und Co. A.-G. G.P. 354,165, 26.8.19.

The resins obtained by distilling hydroxy-fatty acids, *e.g.*, glycollic, lactic, or ricinoleic acid, or castor oil under ordinary or reduced pressure are mixed with phenols and diluted with mineral oil or other desired hydrocarbon. The insoluble resins yield with the phenol a colloidal solution which is absorbed by the animal hide and can serve as a substitute for the materials used in chamoising and oil tanning. Mixed with mineral oils these colloidal solutions yield emulsions which can be employed in stuffing or fat-liquoring vegetable-tanned leather. —D. W.

Plastic material made from casein. R. H. Abrey. E.P. 183,972, 30.5.21.

Casein is soaked in water, dissolved in an alkaline solution, and precipitated with a mixture of zinc sulphite, potassium or sodium metabisulphite, glacial acetic acid, and alcohol, which has been treated with zinc and milk of lime. The precipitate is worked into a tough mass, treated with formaldehyde, and dried.—H. C. R.

Albuminous matter; Process for separating —— from glue solutions prepared from bones. Plauson's Forschungsinstitut. G.P. 355,879, 13.9.19.

The glue solution is treated with ether or mixtures of ether with alcohol, acetone, etc. The extracted albuminous matter has a high food value, and the adhesive power of the glue is improved by its removal.—H. C. R.

[Waste tanning] liquors; Selective removal of organic matter from ——. C. L. Peck, Assr. to The Dow Co. U.S.P. 1,426,596, 22.8.22. Appl., 1.7.19.

Tannery liquors are subjected to a flotation process by which hair is selectively removed from fleshings etc.—A. G. P.

Leather; Process for the treatment of —— with indiarubber. A. McLennan. U.S.P. 1,425,530, 15.8.22. Appl., 21.1.22.

See E.P. 179,969 of 1920; J., 1922, 560 A.

XVI.—SOILS; FERTILISERS.

Selenium; Action of —— on the metabolism of plants in presence of the radioactivity of the air and soil. J. Stoklasa, P. Kricka, J. Penkava, J. Zelenka, J. Chmelar, and V. Jansky. Biochem. Zeits., 1922, **130**, 604—643.

The authors have examined the action of ions containing selenium in the presence of and absence of radium emanations on the growth of azotobacter, the germination of seeds, and the development of plants. Sodium selenite inhibits the growth of *Azotobacter chroococcus*, but the inhibition is overcome by radioactivity. Both selenite and selenate are detrimental to the germination of seeds, the selenite being the more powerful. Radioactive air accelerates the germination of seeds and inhibits the toxic action of selenites and selenates on the growth of plants. In water culture media very minute quantities of selenates can accelerate the growth of plants, but minute quantities of selenites and larger quantities of selenates inhibit. Radioactive water of weak activity stimulates the growth of plants, and may completely inhibit the toxic action of selenite ions.—H. K.

Patents.

Phosphatic fertiliser material and process of making the same. L. R. Coates. U.S.P. 1,425,747, 15.8.22. Appl., 1.9.21.

Material containing superphosphate is mixed with a material containing an alkaline calcium compound. The mixture is wetted and converted into a condition into which it can be strewn as fertiliser. —H. H.

Fertilisers; Process of preventing disintegration of ——, more especially of calcium cyanamide. W. Schwarzenauer. G.P. 306,237, 4.4.16. Addn. to 304,965.

Other oils, or fats, are used in place of the distillate derived from bituminous shale referred to in the previous patent (J., 1921, 314 A).—J. S. G. T.

Seed corn; Fungicide for treating ——. Farbw. vorm. Meister, Lucius, u Brüning. G.P. 353,014, 31.7.20.

Acetaldehyde is employed, either alone or in conjunction with other fungicides and substances, such as water or infusorial earth, reducing the risk of fire. The germinating power of the seeds is much less affected than is the case when formaldehyde is used.—J. S. G. T.

Fertiliser; Process of manufacturing a dustless, non-corrosive ——. W. Schrauth. G.P. 353,493, 22.1.20.

Calcium cyanamide is treated with naphthenic acids, if necessary mixed with neutral oils such as phenol-free tar oil or petroleum distillates. —J. S. G. T.

XVII.—SUGARS; STARCHES; GUMS.

White sugar; Deterioration of Mauritius —— during storage. H. A. Tempany and D. D'Emmerez de Charmoy. Bulletin 24 (General Series), Dept. Agric., Mauritius, 1922.

Moulds, bacteria, and torulæ are all concerned in the deterioration of white sugar (containing about 99% of sucrose and 0·15—0·30% of moisture), the most destructive of the three being the last mentioned, the forms of which encountered by the authors differ from those described by other investigators. Mauritius white sugars have a ratio of moisture to non-sugar well below the figure generally regarded as safe, and primarily the cause of their deterioration is the absorption of moisture from the atmosphere under unsuitable conditions of storage. Individual samples exhibited considerable differences in their liability to deteriorate, the reason for which may be the variation in the size of grain. Deterioration in Mauritius warehouses was noticed to be mostly confined to the layers of bags in contact with the floor, which effect appears to be due to the greater fluctuations of temperature and corresponding increases in the relative humidity of the air at these places, and it was observed that where non-conducting floors existed deterioration was practically absent. Therefore, the authors advise that warehouses for the storage of sugar should be solidly constructed, fitted with doors and windows capable of being tightly closed, and especially they should be provided with floors of non-conducting materials. They should be opened as infrequently as possible, and if possible provided with some means of drying the air, in which latter connexion it may be possible to utilise the hygroscopic property of jute, which was observed to be capable of absorbing 35% of its weight of moisture from the air in 10 days. Another practice counteracting the tendency to absorption of moisture is to use crinkled paper linings for the jute bags, direct contact with the air being lessened in this way. (*Cf.* J., 1918, 275 A; 1919, 549 A; 1920, 583 A.)—J. P. O.

Beet juice; Liming raw —— and the separation of the resulting precipitate by subsiding. V. Skola. Z. Zuckerind. Czecho-slov., 1922, **46**, 601—611, 625—629.

Experiments carried out with the object of effecting a preliminary separation of the albuminoids from beet juice by the addition of lime and subsiding, showed that the rate at which the precipitate settled out was not dependent solely on the amount of lime, but largely upon the manner in which the addition was made. Generally the best results in respect of rapidity of subsiding were obtained by running the diffusion juice into milk of lime while constantly stirring; under these conditions when using 1% CaO about 0·2% CaO was retained in the sediment. A less favourable result was obtained when about 0·2% CaO in the form of milk of lime was added to the juice and the mixture heated to about 80° C.—J. P. O.

Beet juice; Rate of decomposition of some nitrogenous constituents of —— by lime. J. Vondrák. Z. Zuckerind. Czecho-slov., 1922, **46**, 483—490, 533—539, 589—597.

Laboratory experiments carried out with aqueous solutions of various amides in the presence of lime, under conditions resembling those prevailing in the factory during defecation, showed glutamine to be very readily decomposed, asparagine more slowly, and choline and allantoin only inappreciably. A more rapid decomposition of asparagine resulted when the lime was added in the cold and the solution subsequently heated, than when the addition was made at a high temperature, and it is therefore suggested that in the factory defecation should be carried out in the cold. As a means of preventing the retrogression of the alkalinity during evaporation and boiling, it is advisable that lime should be added in the second carbonatation, the saturation at this stage being carried out with carbon dioxide at 100° C.—J. P. O.

Cane juice; Influence of the amino-acids of —— in inhibiting inversion. J. W. L. van Ligten. Archief Suikerind. Nederl.-Indië, 1922, **30**, 216—221. Int. Sugar J., 1922, **24**, 439.

Experiments are described demonstrating that the impurities which are present in cane juice (presumably principally the amino-acids) are capable to a marked extent of inhibiting the inversion of sucrose by hydrogen-ions at high as well as at low temperatures.—J. P. O.

Molasses; Exhaustibility of (Java) cane —— in connexion with its composition. H. Kalshoven. Int. Sugar J., 1922, **24**, 416—419.

In order to obtain a nearer insight into the influence which the composition of a molasses may have upon its exhaustibility, determinations of sucrose, reducing sugars, ash, and gum were made on a large number of samples of this product, which had attained equilibrium at room temperature, further crystallisation not being possible. These results showed that a high dry substance content causes a low purity under otherwise like conditions; that a high content of reducing sugars gives *ceteris paribus* a low purity; that the percentage of gums usually occuring exerts no appreciable influence on the purity; and lastly that the non-sugars present (especially the salts) may either increase or diminish the purity.—J. P. O.

Fructose [lævulose]; Preparation of ——. T. S. Harding. J. Amer. Chem. Soc., 1922, **44**, 1765—1768.

A solution of sucrose (2000 g.) in water (6000 c.c.) is acidified with glacial acetic acid (2 c.c.) and treated with such a quantity of invertase that hydrolysis is complete in about 18 hrs. at 20°—30° C. A few grams of active decolorising carbon is added and the solution is filtered. The clear, colourless filtrate is immediately concentrated to a syrup of about 90—95% total solids in a vacuum at as low a temperature as is possible by the use of a good water pump. The thick syrup is mixed with 2 vols. of hot glacial acetic acid, cooled, seeded with dextrose, and allowed to crystallise at 15°—20° C. during 3—4 days. The dextrose is removed and washed thoroughly with glacial acetic acid; its weight should be 36—37·5% of that of the sucrose taken. The filtrate is diluted with 2 vols. of distilled water and concentrated to a thin syrup in a vacuum at a low temperature. The resulting thin syrup is again diluted with water and subsequently concentrated at a low temperature until it contains about 90—95% of total solids. The final syrup is mixed with an equal volume of hot glacial acetic acid, the mixture is cooled somewhat, seeded with lævulose and allowed to remain at 15°—20° C., crystallisation being usually complete in 2—3 days. The crystals are removed and washed with glacial acetic acid. The yield of crude lævulose is 23·5—28% of the weight of sucrose taken. Further purification is effected by dissolving the crude product (400 g.) in boiling ethyl alcohol (75%, 200 c.c.), adding absolute ethyl alcohol (300 c.c.) and decolorising with active carbon. The filtered solution is diluted further with ethyl alcohol (100 c.c.), seeded with lævulose and allowed to crystallise in a desiccator at the atmospheric temperature. The yield is 75—80% of the weight of crude lævulose taken. Generally a second crystallisation by the same method is necessary to obtain a pure product.—H. W.

Maltose; Action of ozone on pure solutions of ——. C. W. Schonebaum. Rec. Trav. Chim., 1922, **41**, 501—502.

Treatment of 5% solutions of maltose with ozone for 3 hrs. at ordinary temperatures and at 70° C. effects no decomposition if the solution is neutral. In $N/10$ acid solution no decomposition occurs in the cold, but rapid inversion takes place at the higher temperature. In $N/10$ alkaline solution 35% of the sugar is decomposed in the cold; in heated solution it is rapidly destroyed. Formic acid is a primary product; water and carbonic acid are the final products.—H. J. E.

Dextrose, lævulose, sucrose, lactose and maltose; Action of hydrogen peroxide on pure solutions of ——. C. W. Schonebaum. Rec. Trav. Chim., 1922, **41**, 503—508.

The object of the investigations was to ascertain whether hydrogen peroxide could be used industrially for purifying sugar solutions. The method used was to add 4 c.c. of a 3% neutral solution of hydrogen peroxide to 4 g. of sugar dissolved in 80 c.c. of solvent; after 3 hrs. the solution was diluted to 100 c.c. and analysed. The solvents used for the sugar were water, $N/10$ sulphuric acid, and $N/10$ caustic soda; in each case two determinations were made, at ordinary temperature and at 70° C. Control experiments were also carried out. In general under these conditions no decomposition of the sugar occurred except in the case of sucrose, which was inverted in neutral solution to the extent of about 10%. The general conclusion is drawn that thin syrups may be purified with hydrogen peroxide of the strength indicated, provided that the solution is feebly alkaline. With increased concentration of the peroxide, a proportion of the sugar is decomposed.—H. J. E.

Invert sugar; Relative sweetness of ——. J. W. Sale and W. W. Skinner. J. Ind. Eng. Chem., 1922, **14**, 522—525.

If sucrose is assigned a sweetening value of 100, the sweetening value of invert sugar is only 85; since, however, 100 units of sucrose when inverted become 105 units of invert sugar, the net loss of sweetening value by the inversion of 100 units of sucrose is about 11 units. Invert sugar syrup prepared with invertase and concentrated by boiling under reduced pressure is superior to syrups prepared with acid, being free from "harsh" taste though having a slight "candy" flavour.
—W. P. S.

Maize starch syrup [glucose]; Researches on ——. E. Parow. Z. Spiritusind., 1922, **45**, 229.

Chemical examination reveals but little difference between syrups prepared from maize starch and potato starch, but the latter are usually more satisfactory when subjected to the "confectioner's test" (*i.e.*, little or no discoloration on heating to 145° C.). Complete analyses of a number of starches and syrups indicated that the discoloration on heating was influenced by the fat and protein contents of the syrups. The addition of fat to a syrup increased the discoloration. A syrup with 0·06% fat and 0·09% protein showed little alteration on heating to 145° C.; but others having 0·14—0·19% fat and 0·19—0·39% protein were badly discoloured. High fat content may frequently be avoided by limiting the amount of oil added to prevent frothing in the vacuum apparatus during the manufacture of glucose.—A. G. P.

Starch; Combination of —— *with iodine.* H. v. Euler and S. Bergman. Kolloid-Zeits., 1922, **31**, 81—89.

Aqueous solutions of soluble starch dissolve more iodine than pure water and the solubility of iodine in soluble starch solutions containing potassium iodide is greater than the sum of the solubilities in solutions of the two constituents separately. The power of starch to take up iodine is therefore increased by the presence of potassium iodide. (*Cf.* J.C.S., Oct.)—J. F. S.

Starch; Combination of —— *with iodine.* H. v. Euler and S. Landergren. Kolloid-Zeits., 1922, **31**, 89—90.

The amount of iodine extracted from toluene solutions of iodine by soluble starch solutions containing a constant quantity of potassium iodide does not increase with increasing concentration of starch.
—J. F. S.

Polysaccharides; Constitution of ——. *I. Xylan and its acetyl derivatives. I.* S. Komatsu and K. Kashima. Mem. Coll. Sci. Kyoto, 1922, **5**, 307—314.

Xylan was prepared from maize cobs by extraction with caustic soda and repeated precipitation with alcohol. Unlike xylan from wheat straw, acetylation of the product was difficult. The monoacetyl derivative was prepared by heating with acetyl chloride under pressure or by the action of acetic anhydride in acetic acid solution with chlorine and sulphur dioxide as catalysts (J., 1921, 8 T). The diacetyl derivative resulted from treatment of xylan with acetyl chloride using pyridine or zinc chloride as a catalyst, and from further acetylation of the monoacetyl compound in the presence of chlorine and sulphur dioxide. Xylan is rapidly hydrolysed by dilute hydrochloric or sulphuric acid, yielding *l*-xylose. The velocity constants of the hydrolysis of xylose and its acetyl derivatives have been worked out.—A. G. P.

Patents.

Diffusion apparatus for the extraction of sugar from the beet. A. Rak. E.P. 166,527, 5.7.21. Conv., 13.7.20.

The apparatus comprises a continuous battery of units, each consisting of an open-topped diffuser, arranged vertically and enlarged towards the bottom, and a slice-press of the spiral type, the bottom of the diffuser communicating with the bottom of the slice-press by a conduit enlarged towards the slice-press end, and blade and shovel mechanism for feeding the slices through the conduit, the diffusion of the material taking place successively in several stages according to the number of units employed. In order to compensate for the diminution of the volume of the slices at the preliminary stage, two units may be provided for the first stage communicating with a single series of units for the subsequent stages.—J. P. O.

Sugar juice; Treatment of ——. W. Mauss. E.P. 182,855, 8.3.21.

The mechanical impurities (cane chips, particles of gum, wax, etc.) are removed from the juice, preferably by centrifuging, the residue being washed with water while in the machine, discharged, mixed with more water, again centrifuged, and finally discharged, while the water finally separated is used for maceration during milling. The juice is then treated for the separation of its chemical impurities, *e.g.*, by the sulphitation process, the precipitate resulting being removed, preferably by filtration, and washed with water, these wash-waters being also used for maceration during milling.—J. P. O.

[Sugar] centrifugals; Method of and means for washing ——. R. A. Steps, Assr. to Sugar Machinery Co. U.S.P. 1,423,583, 25.7.22. Appl., 7.1.20.

A vertically thin, elongated spray of wash-water is made to sweep substantially from the top to the bottom and from the bottom to the top of the centrifugal, a nozzle and means to oscillate it at speeds varying at different levels in proportion to the thickness of the mass of sugar being provided.
—J. P. O.

Refined massecuite; Process for the manufacture of ——. A. Hinze. G.P. 353,194, 1.4.21.

A small part of the sugar to be worked up is dissolved in water at 60°—80° C. to give a saturated solution, in which the remainder of the sugar in a finely-divided form is stirred and the mixture is then boiled for a short time. The sugar does not become yellow in the process and less heat is required than in the older methods.—A. R. P.

Lactose; Process for purifying ——. E. Trutzer. G.P. 355,020, 28.11.20.

Solutions of crude milk-sugar are treated with calcium aluminate to adsorb or precipitate non-sugars, thus avoiding any excess of free calcium hydroxide and ensuring a good yield of lactose.
—A. R. P.

Starch; Manufacture of —— *[from wheaten flour].* F. H. Campbell. E.P. 182,829, 11.1.21.

In the manufacture of starch, wheaten flour is subjected to the action of a single proteolytic enzyme, *e.g.*, pepsin or trypsin, whereby the nitrogenous constituents are converted into water-soluble substances, without the starch or its envelope being affected. In an experiment 0·04% of pepsin (on the weight of flour) was heated in slightly acidified water to 40°—50° C., the flour added, and the temperature maintained while constantly mixing for 1½—2½ hours, after which the starchy matter was separated in a centrifuge and washed with water till free from acid.—J. P. O.

Starch; Method and apparatus for separating gluten from ——. Corn Products Refining Co., Assees. of R. G. Brindle. E.P. 159,838, 3.3.21. Conv., 8.3.20.

Starch containing gluten is aerated to produce a froth which is maintained in a substantially stable and quiescent condition so as to keep the bubbles of the froth from breaking until the starch liquor has drained therefrom, after which it may be subjected to a further aeration until it has reached a condition at which a stable froth cannot be obtained. It is then run into a vessel in which it separates by stratification into a lower layer of refined starch, an upper of nearly clear water, and an intermediate stratum of mixed starch, gluten, and water. The intermediate layer is withdrawn from the vessel, and subjected to further aeration.—J. P. O.

Dextrin; Apparatus for manufacturing ——. J. J. Merrill, Assr. to Corn Products Refining Co. U.S.P. 1,425,497, 8.8.22. Appl., 2.11.17.

The reaction vessel contains a rotary agitator provided with a number of blades. The upper and lower end portions of each blade stand at an angle to each other and the corresponding end portions of the blades are substantially parallel one with another.—J. R.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Fat-coloration in —— *as a criterion of age, quality, and degeneration.* Bernfeld. Woch. Brau., 1922, **39**, 195.

The presence of fat in yeast cells may be rendered evident by staining with either alkanna or Soudan III. An aqueous suspension of the yeast similar in consistency to that leaving the separators is stirred with alcoholic solution of Soudan III., saturated in the cold, this being added drop by drop until an orange-red coloration is obtained; the action of the colouring matter is continued for 30—80 minutes. The extent to which the colour is taken up increases with the number of generations; thus, if the time during which the dye acts is constant, cells of the first generation may show no colour, whilst those of the third generation exhibit small, slightly tinted points and those of the fourth larger and distinctly coloured fat drops. Small cells are usually richer in fat than older ones. The results obtained may be vitiated if the staining is prolonged, owing to the toxic action of the alcohol or dye coming into play. If 0·005% of Methylene Blue is mixed with the Soudan III., dead cells may be detected at the same time.—T. H. P.

Yeast fermentation; Simple contrivance for the automatic registration of ——. E. Sieburg. Biochem. Zeits., 1922, **130**, 459—462.

The evolution of carbon dioxide from a sugar solution and yeast is recorded on a kymograph by arranging that the fermenting solution is contained in the closed limb of a U-tube with a lower layer of mercury, on the surface of which there is a float carrying a pointer. By arranging a series of such U-tubes comparative measurements of various yeasts on the same substrate, and of the same yeast on various substrates, and the influence of accelerators can be recorded continuously by the tracings.—H. K.

Fermentation; Accelerators of ——. H. v. Euler and S. Karlsson. Biochem. Zeits., 1922, **130**, 550—555.

Washed dry yeasts, free from co-enzyme, are not activated by juices and extracts containing much vitamin-B, but there is marked acceleration of fermentation by washed dry yeast on addition of the co-enzyme.—H. K.

Invertase; Inactivation of —— *by small quantities of silver salts.* H. v. Euler and K. Myrbäck. Z. physiol. Chem., 1922, **121**, 177—182.

Euler and Svanberg had previously shown (*cf.* J., 1920, 795 A) that whilst invertase was inhibited by silver salts proportional to their concentration, mercuric salts behaved differently, the results falling on a curve. A re-examination of the effect of silver salts shows, however, a parallelism with the mercuric salt curves, the previous results being due to the fact that the inhibitive power depends on the concentration of the enzyme.—H. K.

Invertase preparations; Analytical investigation of ——. H. v. Euler and K. Josephson. Svensk Kem. Tidskr., 1922, **34**, 74—81. Chem. Zentr., 1922, **93**, III., 383.

The authors have estimated the ash, carbohydrates (by Molisch's colorimetric method), nitrogen, and phosphorus in a number of invertase preparations of known inverting powers. The poisoning of invertase by silver nitrate observed by Myrbäck is discussed, and the conclusion is drawn that 0·1% of the dry matter of yeast consists of pure invertase, about 0·3 g. of the latter occurring in 1 kg. of pressed yeast.—T. H. P.

Carbohydrates; Acetone and butyl alcohol fermentation of various ——. G. C. Robinson. J. Biol. Chem., 1922, **53**, 125—154.

The fermentative ability of an organism of the *Granulobacter* type, isolated from a sample of fresh barley, towards various carbohydrates was studied. The course of fermentation was followed by making periodic estimations of the titratable acidity of the media and of the amount and, where possible, the composition of the carbohydrates present. The carbohydrates studied fell into two groups according to the type of fermentation which occurred. In the first group, which consisted of dextrose, lævulose, mannose, sucrose, lactose, and starch, the acidity of the media, after reaching a maximum, showed a decided fall, whilst the carbohydrate was completely consumed. The second group comprised galactose, xylose, arabinose, raffinose, melezitose, inulin, and mannitol. In these cases the high acidity persisted and the consumption was incomplete. Dextrin fell into the first or second group according as it was prepared by the hydrolysis of starch with malt amylase or with acid. Trehalose, rhamnose, melibiose, and glycerol were not fermented. With mixtures containing dextrose and either sucrose or lactose, dextrose was preferentially consumed. Maltose, however, was fermented concurrently with dextrose, lævulose, or mannose. Galactose was more completely consumed in the presence than in the absence of dextrose. From the experimental data it is concluded that the organism secretes the enzymes amylase, inulinase, and maltase, but not invertase, lactase, or raffinase. Raffinose is hydrolysed to melibiose and lævulose by sucrase within the cell.—E. S.

Hexoses and related compounds; Fermentation of —— *by certain pentose-fermenting bacteria.* W. H. Peterson, E. B. Fred, and J. A. Anderson. J. Biol. Chem., 1922, **53**, 111—123.

The action on various sugars of four cultures of the group of pentose-fermenting organisms previously described (J., 1922, 72 A) has been examined. Dextrose, lævulose, lactose, raffinose, and melezitose were converted almost quantitatively into lactic acid, small quantities of carbon dioxide, which is regarded as a product of cell respiration, also being produced. With the last three sugars the action was slow, and, when the cultures became old, a secondary fermentation began with the production of volatile acids. Mannitol was fermented differently from the sugars, thus showing the influence of the terminal alcohol group. With one exception, in which no volatile acids were formed, the products from this substance were lactic acid, ethyl alcohol, formic acid, and acetic acid. The action of the pentose-fermenting bacteria resembles that of *Streptococcus lactis*. The lactic acid produced by the former, however, is always optically inactive whereas that produced by the latter is active.—E. S.

Drying yeast; Apparatus for ——. E. Klein. E.P. 176,340, 10.2.22. Conv., 3.3.21.

The apparatus comprises a rotating tank with air inlets and outlets and an intermediate floor permeable to air and provided with oblique air conduits the direction of which substantially coincides with that of the movement of the material on the bottom. The floor is composed of two superposed plates provided with bevelled portions arranged to form nozzle-like air passage spaces which extend obliquely to the plane of the plate. The tank is provided with a stationary cover which carries a stirring or disintegrating device. When the yeast reaches a certain degree of fineness it is separated and carried by air currents into a series of collecting tanks where the drying is completed. The escaping air containing yeast particles meets numerous baffle plates and with the repeated change in the direction of the air the yeast particles are separated.—J. R.

Yeast; Growing of ——. B. A. Stagner, Assr. to National Retarder Co. U.S.P. 1,425,065, 8.8.22. Appl., 6.7.18.

Suitable carbohydrate material and the products of hydrolysis of keratin or material containing keratin are supplied to the seed yeast in order to assist in its growth and to supply nitrogenous material. The resulting yeast is of good colour, odour, and keeping quality, and is suitable for use in the manufacture of leavened bread.—J. R.

Malt preparation; Process for producing a —— *for brewing purposes.* F. Vydra. E.P. 184,381, 19.8.21.

Bruised or ground malt is mashed with water, partly or completely saccharified, and kiln-dried at 110° C. The product is used in small amounts in brewing beer.—A. G. P.

Diastatic preparations; Process for making stable, dry ——. Diamalt A.-G. G.P. 354,944, 8.7.16.

Highly diastatic malt extract is incorporated with inorganic colloidal matter which binds the diastase colloidally; the dry product forms a colloidal solution with water. In order to re-activate the adsorbed diastase, alkali hydroxide is added either to the dry product or to its solution in water. Colloidal silica is specially suited for use as the inorganic colloid. The product is very stable to dry heat, easily analysed, keeps well, and forms solutions of high diastatic power.—H. C. R.

Alcohol; Dehydration of ——. J. Van Ruymbeke. E.P. (a) 184,036, 15.7.21, and (b) 184,129, 22.3.22.

(a) Alcohol of 92—93% concentration as obtained in the usual rectifying process is heated and the vapours are brought in contact with glycerin in a rectifying column through which a counter current of glycerin flows. By suitably regulating the rates of flow of the glycerin and alcohol vapour, the vapour leaving the column when condensed in the usual manner gives an alcohol of 98—99% concentration. The glycerin which flows to the bottom of the column carries away both alcohol and water. This alcohol may be recovered in a second rectifying column by injecting steam and passing the recovered alcohol to the primary rectifying apparatus. The aqueous glycerin is then concentrated and used to dehydrate further amounts of 92—93% alcohol. (b) Instead of glycerin alone, a solution containing glycerin and an anhydrous salt or salts of a hygroscopic nature such as calcium chloride, zinc chloride, or potassium carbonate, may be employed with increased efficiency. By the use of such a mixture in the rectifying column an alcohol of 99·8% concentration or even higher may be obtained. After use the mixture of glycerin and salt is distilled in a current of steam to recover the alcohol and the residue concentrated by heating *in vacuo* at 160° C.—J. R.

Dealcoholising beverages. H. Heuser. U.S.P. 1,426,066, 15.8.22. Appl., 4.6.19.

Beverages are heated under reduced pressure and the vapours evolved carried away to a cooled receptacle.—A. G. P.

Distillery waste; Process of recovering volatile organic acids from ——. L. M. Burghart, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,426,457, 22.8.22. Appl., 24.6.18.

The sugary material is mixed with a soluble caustic alkali and heated in a furnace. The clinker containing soluble oxalates and salts of other acids, is extracted with acidified water. Lime is added to precipitate calcium oxalate, after the removal of which the liquor is evaporated, treated with a non-volatile mineral acid and alcohol, and the esters formed collected.—A. G. P.

Glycerin; Production of —— *by fermentation.* A. T. Cocking and C. H. Lilly. U.S.P. 1,425,838, 15.8.22. Appl., 23.8.20.

See E.P. 164,034 of 1919; J., 1921, 557 a.

XIXa.—FOODS.

Self-raising flour; Determination of carbon dioxide in ——. B. R. Jacobs. J. Ind. Eng. Chem., 1922, 14, 419—420.

Five grams of the flour is placed in a flask connected with an absorption vessel containing a definite volume of standardised barium hydroxide solution, 100 c.c. of 0·1% diastase solution is added to the flask, and a current of air free from carbon dioxide is passed through the apparatus while the flask and its contents are heated, first at 70° C. for 10 mins. and then at 100° C. for 25 mins. The mixture is finally boiled for a few seconds, the absorption vessel then disconnected, and the excess of barium hydroxide titrated, using phenolphthalein as indicator. If it is desired to determine the residual carbon dioxide, the operation is continued after the addition of hydrochloric acid to the contents of the flask.—W. P. S.

Urea; Value of —— *for increasing the production of milk from cows.* W. Völtz, W. Dietrich, and H. Jantzon. Biochem. Zeits., 1922, **130**, 323—431.

A detailed description is given of a large number of experiments on the value of urea, alone, and mixed with feeding materials such as potatoes or beet poor in protein, in comparison with earth-nut cakes. The minimum maintenance demand of digestible protein was 0·33 kg. per 1000 kg. of cow per diem. The yields of milk and of the constituents of milk were invariably increased by administration of urea; not more than 150 grams per day per cow must be given.—H. K.

Casein; Products of prolonged tryptic digestion of ——. S. Fränkel and P. Jellinek. Biochem. Zeits., 1922, **130**, 592—603.

When casein is digested with trypsin until the bromine reaction for tryptophan is negative, the filtrate after precipitation with Hopkins' reagent gives on removal of mercury and addition of alcohol, racemic hydroxyproline in 0·8% yield. From the filtrate mercuric chloride precipitates histidine anhydride dihydrochloride, m.p. 285°, in small quantity. The mercuric chloride precipitate in alkaline solution contained ammonium and methylammonium chlorides.—H. K.

Proteins and their derivatives; New combined fractionation method for separating ——. M. A. Rakusin. Biochem. Zeits., 1922, **130**, 432—441.

The filtrates from 95% alcoholic extracts of a large number of animal and vegetable proteins and of enzymes, were tested qualitatively by various colour reactions and found to contain carbohydrate and nitrogenous substances in most cases. Pepsin-fibrin peptone can be fractionated by extraction with 95% alcohol and subsequent successive treatment of the filtrates with a 10% suspension of aluminium hydroxide for periods of 24 hours each, into a number of fractions which differ from one another in their colour reactions to various protein and carbohydrate reagents.—H. K.

Proteins; Kinetics of the coagulation of —— *by heat.* H. Lüers and M. Landauer. Z. angew. Chem., 1922, **35**, 469—471.

The coagulation of proteins by heat is considered as occurring in two stages, viz., a chemical process of denaturation, and the subsequent physical flocculation of the denatured particles. The initial process in the case of the plant albumin, leucosine (obtained from barley or malt extract) was found to be a reaction of the first order. Working at $p_H=6{\cdot}09$ and temperatures between 52·9° and 57·05° C., the temperature coefficient was 1·47 per degree. —A. G. P.

Proteins; Proteolysis in material containing ——. G. Chabot. Bull. Soc. Chim. Belg., 1922, **31**, 193—204.

Experiments on proteolysis were made with the aid of green malt such as is used in the manufacture of yeast by the aeration method, this material being rich in proteolytic enzymes and containing sufficient protein to allow the course of proteolysis to be easily followed. The malt was used at a concentration of 20%, and changes due to the action of micro-organisms were excluded by the addition of sodium fluoride solution. The extent of peptonisation was measured by determinations of amino-acid nitrogen by Sörensen's method before and after proteolysis. Sodium fluoride had no appreciable effect on the percentage of protein decomposed at 17° C.; at 35° C. it appeared to exert a slight inhibiting action, whilst at 50° C. it facilitated decomposition to a small extent. The optimum temperature for peptonisation over a period of 4 hrs. was about 45° C., and 25·17% of the total nitrogen was found as amino-acids capable of titration with formaldehyde. In absence of sodium fluoride, the optimum temperature was 35° C. Determinations of the optimum time at 45° C. in presence of sodium fluoride showed that continuance of the action from 15 hrs. to 24 or even 36 hrs. gave but a small increase in % of nitrogen as amino-acid. Investigation of the optimum reaction of the medium carried out by addition of different amounts of $N/10$ sulphuric acid and $N/10$ caustic soda showed that the addition of 0·2 g. of sulphuric acid per 100 g. of malt gave the greatest yield of amino-acid; this addition corresponds to the neutralisation of about three-fourths of the natural alkalinity of the malt. Hydroxyl ions, even in small quantity, exert an inhibiting action, which increases with the concentration. The author discusses briefly the part played in peptonisation by hydrogen ions.—H. J. E.

Eggs; Methods of minimising shrinkage during the storage of ——. L. H. Almy, H. I. Macomber and J. S. Hepburn. J. Ind. Eng. Chem., 1922, **14**, 525—537.

Loss on weight during storage of eggs is mainly due to the escape of moisture through the shells, and is not prevented by preliminary treatment with hot air for 5 mins., or to any appreciable extent by treating the eggs with cold or hot solutions of mineral or organic acids, mineral salts, or soap. Experiments with vegetable, animal, and mineral oils (used as coatings on the eggs) showed that sealing properties are not strictly related to drying properties of the oils. Cottonseed oil makes a very good sealing agent, and the value of mineral oils for the purpose bears a definite relation to their sp. gr., flash pt., and viscosity. Mineral oils are probably preferable to vegetable oils because they are less likely to impart odour to the eggs and are less subject to change during storage. The addition of 1 or 2% of soap increases the sealing value of a mineral oil, but nothing is to be gained by the addition of gums, waxes, or rosin to relatively heavy mineral oils.—W. P. S.

Foods; Method of determining hydrogen sulphide evolved by —— *when cooked at various temperatures.* E. E. Kohman. J. Ind. Eng. Chem., 1922, **14**, 527—529.

The food substance is placed in a 3-litre flask which is fitted in an autoclave supplied with steam from a boiler; the flask is closed with a wooden stopper and a tube extending from just above this stopper to the bottom of the flask allows steam to enter the latter from the autoclave. A delivery tube from the flask passes through the cover of the autoclave and is connected with a condenser provided with a receiver containing bromine solution. The delivery tube is fitted with a tap to control the rate of distillation; if desired, the delivery tube may have a branch capillary tube, which also enters the condenser, this arrangement in conjunction with the tapped tube yielding a more uniform volume of distillate. The distillation is made at 120° C., about 650 c.c. of distillate being collected in 45 mins. The oxidised sulphur compounds in the distillate are determined in the usual way as barium sulphate. In the case of green maize etc., reducing substances other than sulphides are found in the distillate; as measured by permanganate reduction the hydrogen sulphide amounts to about one-tenth of the reducing substances.—W. P. S.

Water-soluble B [vitamin]; Presence of the antineuritic substance ——, *in the chlorophyll-free plants.* C. R. Orton, E. V. McCollum, and N. Simmonds. J. Biol. Chem., 1922, **53**, 1—6.

Vitamin B is present in small quantities in onion roots; it is therefore concluded that this vitamin is not associated with the chloroplasts in plant tissue. The mushroom *Agaricus campestris* is a good source of vitamin B; experiments with Indian-pipe, *Monotropa uniflora*, gave inconclusive results. —E. S.

Water-soluble B [vitamin]; Glacial acetic acid as a solvent for the antineuritic substance ——. V. E. Levine, E. V. McCollum, and N. Simmonds. J. Biol. Chem., 1922, **53**, 7—11.

Glacial acetic is a good solvent for the extraction of vitamin B from plant material. Impurities can be largely removed from such extracts by precipitation with ether.—E. S.

Theobromine and caffeine; Apparatus for the extraction of ——, *with boiling chloroform.* O. P. A. H. Schaap. Pharm. Weekblad, 1922, **59**, 920—923.

The apparatus is a modified Soxhlet extractor, of specified dimensions, the siphon tube being completely outside the extractor tube. The material to be treated is placed in a Schleicher and Schüll thimble, which is supported from below by a wad of cotton wool placed in the extraction tube. A bath of hot water (70°—75° C.) surrounds the latter. The chloroform must boil gently in the extraction tube for ten minutes before siphoning over, and the shape and dimensions of the apparatus and the procedure are of importance in securing this.—S. I. L.

Lye hominy: its discoloration and a new process for its manufacture. E. F. Kohman. J. Ind. Eng. Chem., 1922, **14**, 415—418.

Lye hominy is usually prepared by boiling maize (2100 g.) with sodium hydroxide solution (7 l. containing 52 g. of sodium hydroxide), washing the product with cold water and cooking it; the finished product has a dark or even black colour due to incomplete removal of the alkali by washing. The degree of alkalinity, and consequently the colour, also depends to some extent on the size, shape, and age of the grains. If the grains are subjected to a scrubbing action directly after the treatment with alkali, the outer layer of the grains and the tips are removed, the residual alkalinity is thus decreased, and the product is white.—W. P. S.

Patents.

Blood; Processes for preserving the fluidity of ——. F. W. V. Fitzgerald. E.P. 183,943, 5.5. and 9.11.21.

The initial coagulation of blood is prevented if the calcium salts in the blood are removed, *e.g.*, by precipitation with a neutral or alkaline solution of a soluble oxalate or fluoride or a mixture of both. In addition a preservative may be added.—J. R.

Pectin-containing material; Process of making —— *and resulting product.* F. G. Beylik and N. W. Schwartzlose. E.P. 184,081, 5.9.21.

Pectous materials, such as pectic acid $C_{16}H_{22}O_{15}$ and pectosic acid $C_{32}H_{46}O_{31}$, are prepared from plant materials containing pectin as follows: The material comminuted by crushing or slicing is dehydrated at a low temperature, ground to a fine condition, and extracted with a solvent (such as alcohol) capable of dissolving substantially all the substances present except pectous material and cellular tissue. The residue has pectin, pectic and pectosic acids uniformly distributed throughout the mass. In making jellies, jam, etc. it is only necessary to add a small quantity of the pectous material to the fruit juices which form the basis of the jelly or jam. The cellular tissue present does not interfere with the making of a clear jelly.—J. R.

Vegetable albuminoid and process of producing it. A. Moffatt, Assr. to E. H. Wolcott. U.S.P. 1,425,033, 8.8.22. Appl., 24.8.18.

Vegetable material is subjected to the action of an "amylolytic" acid and then boiled until all the starch originally present is rendered soluble. The resulting mixture is drained free from liquor and the insoluble residue of albuminoids and fats washed free from the soluble products of the amylolysis.—J. R.

Coffee; Method of roasting and packing ground or whole ——. J. A. Reynolds. U.S.P. 1,426,011, 15.8.22. Appl., 4.12.19.

Green coffee is roasted in a vessel from which air is excluded. The volatile products are removed by evacuation, and condensed on a cellulose menstruum. The roasted coffee is stored, together with a portion of the impregnated cellulose, in sealed containers.—A. G. P.

Preserved eggs and process therefor. A. K. Epstein. U.S.P. 1,426,559, 22.8.22. Appl., 9.12.20.

Eggs, after removal from the shells, are mixed with glycerin, frozen, and stored in a frozen condition till required for use.—A. G. P.

Feeding-stuffs; Manufacture of —— *from straw and the like.* E. Beckmann. G.P. 354,822, 2.2.19.

Straw or the like is digested with alkali carbonate solution. Great care is not necessary in washing out the excess alkali carbonate, since it is not injurious to cattle.—J. B. F.

Dehydrated milk. International Dry-Milk Co., and S. M. Dick. E.P. 184,203, 4.2.21.

See U.S.P. 1,374,555 of 1921; J., 1921, 407 A.

Crystallising oils and fats. U.S.P. 1,426,555. *See* XII.

Albuminous matter from glue solutions. G.P. 355,879. *See* XV.

XIXb.—WATER PURIFICATION; SANITATION.

Aeration of quiescent columns of distilled water and of solutions of sodium chloride. W. E. Adeney, A. G. G. Leonard, and A. Richardson. Sci. Proc. Royal Dublin Soc., 1922, **17**, 19—28.

The aeration of quiescent bodies of water, fresh and salt, under natural conditions is effected by a process of mixing of the exposed layer with the unexposed portions of the water to depths of at least ten feet. The mixing is caused by the downward streaming of the constantly changing layer of water exposed to the air. This process is more rapid and more uniformly downward in salt water than in fresh water. The rate of streaming depends largely on the rate of cooling of the surface layer by evaporation, and it is more rapid at temperatures above 10° C. The optimum rate of streaming is reached with a 1% salt solution.—J. F. S.

Effluent from strawboard mills; Treatment and disposal of ——. H. B. Hommon. Proc. Amer. Soc. Civil Eng., 1922, **48**, 1397—1402.

As a result of tests carried out at 7 strawboard mills in America, it is estimated that about 38,500 galls. of effluent is produced in the manufacture of 1 ton of strawboard; on this basis 20,000,000,000 galls. of waste water, containing approximately 161,000 tons of dry suspended solids, was discharged from the various plants in the United States during 1918. Investigation has shown that this waste can be treated at reasonable cost, so that it may be safely discharged into a body of water affording a dilution factor of 5 or 6. For every ton of strawboard produced per day the following should be provided: settling tanks of a combined capacity of 975 cub. ft., filter bed (for drying sludge) made of unscreened cinders, 10 in. deep and 875 sq. ft. in area; filter for settled effluent made of screened cinders (screened over a ¼″ screen) 5 ft. deep and 4171 sq. ft. in area. The raw effluent should be allowed to settle for 2 hrs. in the settling tanks and then run on to the filter bed. From results already obtained it is believed that filter beds, made as described above, with cinders screened over a ¼″ screen, could be used for years for treating strawboard wastes, but would probably require to be flushed once a year, preferably with fresh water, to remove clogging material. The sludge from the settling tank could be used as a fertiliser.—D. J. N.

Carbonyl chloride; Sorption of —— by beechwood charcoal. H. M. Bunbury. Trans. Chem. Soc., 1922, **121**, 1525—1528.

The sorption of carbonyl chloride by beechwood charcoal at 18° C. and 100° C., as measured by Travers' apparatus (Proc. Roy. Soc., 1904, **74**, 126; 1906, A **78**, 9), agrees with the formula $x/m=kp^{1/n}$. At 18° and 100° C., the values of $1/n$ are 0·231 and 0·488 and of k 0·235 and 0·038 respectively. Approximate equilibrium is established after a few minutes, the velocity of sorption being extremely rapid.

—P. V. M.

Bacteria, erythrocytes, and yeast; Use of the ultramicroscope for examination of the action of poisons on the cells of ——. I. Traube and P. Klein. Biochem. Zeits., 1922, **130**, 477—480.

By means of the ultramicroscope it is possible to follow the adsorption of submicrons present in saturated aqueous solutions of a variety of toxic substances such as xylidine, octyl alcohol, nonylic acid, *m*-cresol, thymol, and vuzin on red-blood corpuscles, Soor's bacilli, and yeast cells. The penetration of these substances into the cells and the subsequent break up of the cells through hæmolysis, plasmolysis, etc. can be followed.—H. K.

Invertase, maltase, and α-methylglucosidase; Action of quinine, narcotics and arsenic compounds on ——. P. Rona, Y. Airilla and A. Lasnitzki. Biochem. Zeits., 1922, **130**, 582—591.

The combined inhibitory action of quinine and narcotics on invertase is less than the sum of their individual actions. Arsenious acid, arsenic acid, and atoxyl had no action on maltase or α-methylglucosidase, but methyl arsenious oxide was inhibitory.—H. K.

Formaldehyde. Kühl. *See* XXIII.

Detergent and disinfectant. E.P. 184,248. *See* XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Relation between constitution of —— and Vitali's reaction. P. Hardy. J. Pharm. Chim., 1922, **26**, 172—176.

It has been shown that Vitali's reaction, which was considered to be characteristic of atropine and hyoscyamine, is also given by isoatropylcocaine. The author shows that scopolamine also responds to the test, which is a general test for esters formed by the combination of an alcohol with tropic acid and other acids of analogous constitution.

—H. J. E.

Codeine salts: the hydrobromide. Preparation of solutions for injection. F. Martin. J. Pharm. Chim., 1922, **26**, 176—187.

The author's results on the composition and dehydration of crystallised codeine hydrobromide are in agreement with those of Dott (Pharm. J., 1884, **14**, 917), namely that the crystallised salt loses ½ mol. H_2O when heated on a boiling water bath and the remaining 1½ mols. at about 115° C. The solubility of this salt is considerably increased in presence of sodium benzoate or salicylate; the preparation of solutions for subcutaneous injection, based on this increase in solubility, is described.

—H. J. E.

Colchicine: its assay, isolation and special properties. E. C. Davies and J. Grier. Pharm. J., 1922, **109**, 210—211.

In preparing the alkaloid in quantity by the use of phosphotungstic acid, satisfactory precipitation is only possible in presence of sodium chloride. The best results were obtained by the following method: The powdered seeds and corms are treated with methylated spirit in a Soxhlet extractor in which the boiling flask is placed at the side so that the drug is not exposed to heat. The alcohol is distilled off, the residue extracted with hot water, and any oil removed with ligroin. The impure alkaloid is then extracted with chloroform and the chloroform residue extracted with hot water. This extract is filtered and the filtrate precipitated by phosphotungstic acid in presence of 2% of sodium chloride and 0·5% of hydrochloric acid. The precipitate is collected, washed free from sodium chloride with 0·1% hydrochloric acid, and transferred to a separator containing chloroform. A slight excess of ammonia is added, the chloroform evaporated and residue crystallised from 50% alcohol. No difference was found in the product from seed and corm. The most satisfactory solvents for the extraction of the powdered drug were chloroform, ethyl alcohol, methyl alcohol, and methylated spirit. Assay was carried out volumetrically with Mayer's and Schiebler's reagents and also by precipitation with Schiebler's reagent. It was found that 1 c.c. of Mayer's reagent ($N/20$) is equivalent to 0·011 g. of colchicine. The centrifuge was utilised to obtain more rapid separation of the precipitate, thus increasing the sensitiveness of the method. The results of the above and of gravimetric estimations with Schiebler's reagent established the ratio of

1 part of colchicine to 3·3 of phosphotungstic acid as the proportions in which they combine. The precipitation was carried out in the presence of sodium chloride and hydrochloric acid, the precipitate being washed, dried and ignited; it decomposed at 200° C. yielding $P_2O_5, 20WoO_3$. Colchicine gives a green coloration with alkali, and may thus be estimated colorimetrically in dilute solution. An account of the properties of the alkaloid and also those of colchiceine is given together with the methods of preparation of colchicine salicylate and tannate. A list of the usual tests for colchicine is appended. The authors note that phenol, cresol and thymol give precipitates with the alkaloid and suggest that the tannate and salicylate are not true salts but addition products in which the phenolic rather than the carboxylic group is functioning. —H. J. E.

Hyoscyamine and its sulphate. Preparation and racemisation. A. Goris and P. Costy. Bull. Sci. Pharmacol., 1922, **29**, 113—121. Chem. Zentr., 1922, **93**, III., 268—269.

Hyoscyamine and atropine can be separated by making use of the different solubilities of the free bases in benzene or of the sulphates in alcohol. The conversion of crystalline hyoscyamine into atropine is very slow at 100° C., but is greatly increased if the base has previously been dissolved in chloroform. At 118° C. the conversion is complete in 2 hours. In the dissolved state the transformation occurs more readily in aqueous than in alcoholic solutions, but aqueous solutions of hyoscyamine sulphate are stable even on prolonged heating.—D. F. T.

Plants; Chemical constituents of green ——. XIX. Occurrence of lactic acid and succinic acid in the leaves of the raspberry (*Rubus Idæus*). H. Franzen and E. Stern. Z. physiol. Chem., 1922, **121**, 195—220.

The aqueous extract of raspberry leaves after removal of substances precipitable by lead acetate, contains chiefly calcium, magnesium, and manganese salts of lactic acid with a little succinic acid. The dried leaves contain 1% of lactic acid. The isolation and characterisation of these acids is facilitated by fractionation of the esters, conversion into hydrazides, and condensation with benzaldehyde.—H. K.

Emulsin. II. R. Willstätter and G. Oppenheimer. Z. physiol. Chem., 1922, **121**, 183—194.

In continuation of previous work (J., 1922, 228 A) it is found that those enzyme actions of the emulsin complex which proceed best in a decidedly acid medium follow the unimolecular law, as, for instance, hydrolysis of salicin, arbutin, helicin, and phenylglucoside. By comparing the times at which 50% of the following glucosides have been hydrolysed, helicin, salicin, phenylglucoside, arbutin, methylglucoside, prunasin, and amygdalin, by nine totally distinct preparations of emulsin, it is found that the ratio of the time values for helicin, salicin, and phenylglucoside alone is the same in each case. This is the first quantitative demonstration that one enzyme of the emulsin complex can attack different substrates. This enzyme, phenylglucosidase, is most specific for helicin.—H. K.

Ring-substituted phenylphosphinic and phenylarsinic acids; Comparative study of ——. D. R. Nijk. Rec. Trav. Chim., 1922, **41**, 461—500.

The following improved methods of preparation of these acids are given: *p-Aminophenylarsinic acid.* A mixture of 30 g. of freshly-distilled aniline and 22 g. of dry arsenic acid is heated to 170°—200° C. in an hour, and then at 200° C. for two hours; the product is cooled to 100° C., added to concentrated caustic soda and shaken so as to dissolve as much as possible, then filtered. The filtrate is extracted three times with ether to remove excess of aniline, rendered slightly acid with nitric acid, and evaporated to a small volume. The acid which crystallises on cooling is dissolved in dilute caustic soda and the solution heated gently with animal charcoal and filtered into absolute alcohol. The sodium *p*-aminophenylarsinate (atoxyl) separates in colourless crystals. The yield is somewhat increased with an excess of aniline and corresponds to 25—30% of the arsenic acid used. *5-Nitro-2-aminophenylarsinic* (*nitranilinarsinic*) *acid.* Double the usual yield is obtained by the following method: A mixture of 55 g. of *p*-nitraniline and 10 g. of arsenic acid is heated to 206° C. for 15 min., and at 230° C. or below during the subsequent reaction. *Phenylarsinic acid.* 30 g. of aniline is dissolved in 243 g. of 50% nitric acid with 580 c.c. of water, the whole being cooled on ice. The solution is diazotised with 21 g. of sodium nitrite in a little water. Concentrated caustic soda is then added, the temperature being kept down by a freezing mixture, until the mixture is only feebly acid; the last traces of acidity are removed by addition of sodium acetate. The diazonium nitrate is then added drop by drop with constant shaking, to a mixture of cuprous hydroxide suspended in 200—300 c.c. of water, 33 g. of arsenious oxide, 40 g. of caustic soda, previously dissolved in 100 c.c. water, and ether (about 30 c.c.). The completion of the action is ascertained by testing with β-naphthol. The product is filtered, the filtrate acidified with hydrochloric acid, treated with animal charcoal and evaporated on the water bath until the phenylarsinic acid begins to separate in colourless needles. The greater part of the acid is obtained at this stage; the remainder is extracted by hot absolute alcohol after the mother-liquor has been evaporated to dryness. The yield from 30 g. of aniline was 20 g. of the acid.—H. J. E.

o-Toluenesulphonamide; Oxidation of ——. A. W. Pamfilow. Ber. Polytech. Iwanowo-Wosniessensk, 1921, **4**, 167—168. Chem. Zentr., 1922, **93**, III., 353.

Oxidation of 1 mol. of the sodium salt of the amide with 2·4 mols. of potassium permanganate for 6 hrs. at 60° C. gives 80% of the theoretical yield of saccharin. On oxidation of the free amide by similar means the yield of saccharin is 10—15% lower, and the amount of permanganate used i doubled.—J. B. F.

Hydantoins. Synthesis of the soporific 4-phenyl-4-ethylhydantoin [*nirvanol*]. W. T. Read. J. Amer. Chem. Soc., 1922, **44**, 1746—1755

Phenyl ethyl ketone reacts with an absolute alcoholic solution of ammonium cyanide to form phenylethylaminoacetonitrile, $(C_6H_5)(C_2H_5)C(CN).NH_2$; reaction does not take place in aqueous solution and even in 95% alcohol the yields are very low. The nitrile is converted by potassium cyanate in the presence of glacial acetic acid into the nitrile of phenylethylhydantoic acid, $(C_6H_5)(C_2H_5)C(CN).NH.CO.NH_2$, in 80% yield. When this compound is boiled with hydrochloric acid (20%), it is transformed into 4-phenyl-4-ethylhydantoin in 85% yield. The latter substance may be prepared by the procedure outlined above from phenyl ethyl ketone without isolating and purifying the intermediate products, the yield being 62%. (*Cf.* J.C.S., Oct.).—H. W.

Trihalogen tertiary butyl alcohols; Derivatives of ——. IV. Benzoyl ester of tribromo-tert.-butyl alcohol or brometone benzoyl ester. T. B. Aldrich and J. E. Blanner. J. Amer. Chem. Soc., 1922, **44**, 1759—1762.

Tribromo-tert.-butyl benzoate (brometone benzoate), monoclinic crystals, m.p. 90° C., is prepared in excellent yield by heating molecular proportions of benzoyl chloride and brometone on the water bath until hydrogen chloride ceases to be evolved. It is not readily saponified. In contrast to brometone, the halogen atoms are not readily removed by treatment with sodium hydroxide solution. Its insolubility probably accounts for its lack of physiological action. The nitrobenzoates of chloretone and brometone are prepared similarly by the use of the nitrobenzoyl chlorides or, in the case of the meta compounds, by nitration of the parent esters with concentrated nitric acid. They are not as active physiologically as the alcohols from which they are derived, possibly owing to their insolubility in water.—H. W.

Oxyhæmoglobin; Preparation of crystalline ——. M. Heidelberger. J. Biol. Chem., 1922, **53**, 31—40.

The method described depends upon the fact that the washed corpuscles from dog's or horse's blood crystallise almost completely in the presence of toluene when saturated with a mixture containing four parts of carbon dioxide to one of oxygen. The oxyhæmoglobin so obtained may be recrystallised by dissolving in sodium carbonate solution and re-precipitating by saturation with the above mixture of gases. Salts may be removed from the recrystallised product by pressure dialysis. It is essential to perform all operations in the cold and in the presence of excess of carbon dioxide, and to prevent the oxyhæmoglobin becoming dry at any stage. Using this method, preparations with 96—100% of the theoretical oxygen capacity have been obtained. —E. S.

Creatinine; Determination of ——. K. Pfizenmaier and S. Galanos. Z. Unters. Nahr. Genussm., 1922, **44**, 29—41.

The method given in the "Schweizerisches Lebensmittelbuch" for the determination of creatinine is rapid and simple, but can only be successfully used when light coloured solutions are available for the colorimetric comparison and a colorimeter of the Duboscq type is used. If the solutions are dark in colour or contain sugar the method fails, as animal charcoal cannot be used because it adsorbs creatinine. Colorimetric comparison in cylinders (*loc. cit.*) was found to be unsatisfactory. The method of Sudendorf and Lahrmann (J., 1915, 1027) is of general application and is the only one available for use with dark-coloured solutions. If the authors' instructions are exactly followed and too great an excess of potassium permanganate —especially with very dark-coloured solutions— is avoided, accurate results are always obtained. The methods referred to are described in detail. —H. C. R.

Glyoxalinedicarboxylic acid for the recognition and separation of organic bases. H. Pauly and E. Ludwig. Z. physiol. Chem., 1922, **121**, 165—169.

Glyoxalinedicarboxylic acid forms sparingly soluble and well crystallised acid salts with organic bases. The salts of the following are described: Methylamine, m.p. 240°—245°; dimethylamine, 238°—239°; trimethylamine, 264°—265°; ethylamine, 253°—254°; diethylamine, 180°; propylamine, 212°; *n*-butylamine, 225°—227°; piperidine, 221°—222°; *d*-coniine, 208°—209°; atropine, 93°; hydrazine, above 260°; guanidine, 241°—242°; glyoxaline, 245°; and *l*-histidine, 253°—254°. The solubilities of the last four are very small, of the others between 2 and 45%.—H. K.

Chymosin and pepsin. VII. Experiments on their purification. O. Hammarsten. Z. physiol. Chem., 1922, **121**, 240—260.

The starting material was prepared by extraction of the mucous membrane of the pig's stomach with 0·2% hydrochloric acid and precipitation of the "crude pepsin" as a hyaline mass by half saturation with sodium chloride. Preliminary experiments are described in which the sodium chloride was dialysed away in 0·2% hydrochloric acid and the solution kept at 37° to denature. The solution was then either (1) dialysed against water, (2) precipitated by half saturation with sodium chloride, or (3) precipitated by saturation with ammonium sulphate. The present communication deals mainly with the fractional extraction of the "crude pepsin" by water in a centrifuge, dialysis of the extracts, and analysis of their content in organic matter, pepsin, and chymosin. The successive extracts, except the later ones, compare favourably in activity with Pekelharing's pepsin although the qualitative reactions are different. A comparison of the clotting time on milk and the digestive power by Mett's test of the author's preparation with Pekelharing's preparation showed no parallelism under any conditions. The author's solutions are stable, very faintly acid, and inactivated by neutralising.—H. K.

Chymosin and pepsin. VIII. Relative sensitiveness to alkali of the stomach enzymes of the calf and pig. O. Hammarsten. Z. physiol. Chem., 1922, **121**, 261—282.

Michaelis and Rothstein (Biochem. Zeits., 1920, **105**, 60) found that alkali destroyed chymosin and pepsin from the pig's stomach at the same rate, whilst the author (Z. physiol. Chem., 1915, **94**, 291) found that these enzymes when prepared from the calf's stomach were acted upon by alkali at totally different rates. This is now ascribed to the use of different animals. Chymosin from the pig's stomach is destroyed much more rapidly than chymosin from the calf's, and the same probably applies to the pepsin content. The experiments, moreover, point again to the separate entities of chymosin and pepsin as they are destroyed at different rates.—H. K.

Furfural; Commercial ——. *Its properties and uses. I.* C. S. Miner, J. P. Trickey, and H. J. Brownlee. Chem. and Met. Eng., 1922, **27**, 299—303.

The physical and chemical properties of furfural are described in some detail, together with a number of its condensation products with other organic compounds. A method of manufacture on a large scale from oat-hulls (which should yield nearly 20% of their weight in furfural) by digestion with steam and acid under pressure has been worked out and a production of several tons per month is being made by the process. The toxic effect of furfural is about half that of phenol for gold-fish and its bactericidal action is about one-quarter that of phenol.—A. R. P.

Furfural solutions; Distillation of aqueous ——. H. Bergström. Svensk Papperstidning. Zellstoff u. Papier, 1922, **2**, 139—140.

The distillation constants of dilute aqueous solutions of furfural are as follows:—

Percentage of fnrfural by weight—

In solution	0·1	0·2	0·5	1·0	1·5	2·0	2·5	3·0	3·5	4·0	4·5
In vapour	0·7	1·3	3·4	6·5	9·1	11·4	13·1	14·7	16·2	17·6	19·0

The values are very similar to those found for dilute solutions of methyl alcohol.—J. F. B.

Furfural; Commercial ——. *Its properties and uses. II.* C. S. Miner, J. P. Trickey, and H. J. Brownlee. Chem. and Met. Eng., 1922, **27**, 362—366.

The use of furfural in making resins, varnish, dyes etc. is briefly discussed and a complete bibliography

of furfural and its chief derivatives is appended. Preliminary tests show that it may be used as a solvent for nitrocellulose, hydrated cellulose acetates, and oleic acid.—A. R. P.

Formic acid; Catalytic decomposition of —— on surfaces of platinum and silver. H. C. Tingey and C. N. Hinshelwood. Trans. Chem. Soc., 1922, **121**, 1668—1676.

The thermal decomposition of formic acid in contact with platinum yields carbon dioxide and hydrogen exclusively at temperatures from 235° to 80° C. This is not analogous to the decomposition in contact with glass at these temperatures, as carbon monoxide and water are never formed. The temperature coefficient of the reaction in contact with platinum is approximately the same as that of the corresponding reaction in contact with glass, viz., 1·7—1·8. The "heat of activation," calculated from the formula $d.\log.k/dT=Q/RT^2$, is 22,000 cals. per g.-mol. for platinum, and 28,000 cals. for glass. In contact with silver the decomposition yields mainly carbon dioxide and hydrogen. The temperature coefficient for this reaction is again high, 1·9—2·3, corresponding to a mean "heat of activation" of 31,000 cals. Varying amounts of carbon monoxide are also formed, most of which can probably be accounted for by the reaction in contact with the walls of the glass bulbs used. Platinum foil catalyses only slightly, and silver powder not at all, the formation of carbon dioxide from carbon monoxide and water. Platinum is the most efficient catalyst and is associated with the lowest heat of activation with respect to one and the same mode of reaction, *i.e.*, decomposition into carbon dioxide and hydrogen.—P. V. M.

Trimethylene; Preparation of —— in a pure condition. M. Trautz and K. Winkler. J. prakt. Chem., 1922, **104**, 37—43.

Trimethylene is conveniently prepared by the reduction of trimethylene bromide in amyl alcohol by zinc dust at 100°—115° C. The gas evolved is fractionated at a low temperature in an apparatus which is described, and pure trimethylene obtained with the following constants: vapour density, 1·45—1·49; sp. gr. of liquid, 0·720; m.p., −127°; b.p., −34·5° at 750 mm.; $n_{He}=1{\cdot}000977$.
—W. O. K.

Propylene; Preparation of —— in a pure condition. M. Trautz and K. Winkler. J. prakt. Chem., 1922, **104**, 44—52.

Propylene is prepared in very good yield by passing propyl alcohol or, preferably, isopropyl alcohol over aluminium oxide or fragments of graphite crucibles at 360° C., preferably under diminished pressure. It is purified by passing through a receiver cooled in ice, then over calcium chloride and potassium hydroxide, through a vessel cooled in a mixture of toluene and solid carbon dioxide, and finally over calcium chloride. Pure propylene has the following constants: vapour density, 0—2% higher than corresponds to the molecular weight; sp. gr. of liquid, 0·647; b.p., −47·8° at 750 mm.; it does not solidify in liquid air; $n_{He}=1{\cdot}00102$. The specific volumes of mixtures of trimethylene and propylene in the liquid condition are additive.—W. O. K.

Aldehydes; Reduction of acid chlorides to —— by means of nickel catalysts. H. Schliewiensky. Z. angew. Chem., 1922, **35**, 483.

Attempts to prepare benzaldehyde by the reduction of benzoyl chloride with hydrogen in the presence of a nickel catalyst (*cf.* Rosenmund, J., 1918, 442 A) were unsuccessful. Reaction could not be effected in the presence of catalysts prepared from freshly precipitated basic nickel carbonate which was (*a*) ignited while moist in air to the oxide and subsequently reduced by hydrogen in an electric furnace at 310°—320° C., (*b*) heated directly in the tube at 310°—320° C., and subsequently reduced at the same temperature, and (*c*) dried at 100° C. in air and then ignited and reduced in hydrogen at 310°—320° C. Failure cannot be attributed to inactivity of the catalyst, which rapidly caused the hydrogenation of fats.—H. W.

Aldehydes; Reduction of acid chlorides to —— by means of nickel catalysts. K. W. Rosenmund. Z. angew. Chem., 1922, **35**, 483.

In reply to Schliewiensky (*cf. supra*) it is pointed out that attention has already been drawn (*cf.* J., 1918, 442 A) to the variability in the behaviour of palladium and nickel as catalysts in the conversion of acid chlorides to aldehydes by hydrogen. A trustworthy procedure has been given in the case of palladium (Rosenmund and Zetzsche, J., 1921, 321 A); a modified method will be published in the case of nickel.—H. W.

Formaldehyde; Determination of —— in impure solution. F. Kühl. Collegium, 1922, 133—142.

An investigation of the sulphite method (*cf.* Auerbach, J., 1905, 1187), Blank and Finkenbeiner's method (J., 1899, 79), and Romijn's iodine potassium cyanide methods (J., 1897, 366) shows that the potassium cyanide method is the best.—D. W.

Pinene hydrochloride; The borneol obtained from the magnesium compound of ——. G. Vavon and A. L. Berton. Comptes rend., 1922, **175**, 369—372.

Pinene hydrochloride was prepared by treatment of French turpentine with gaseous hydrogen chloride, and was treated with Grignard's reagent. The product on oxidation and subsequent treatment with ice-water, yielded an alcohol which was found to be a mixture of borneol and isoborneol. If oxidation takes place at a low temperature, the proportions in which these two substances are obtained are about equal, but at a higher temperature borneol free from isoborneol may be produced. The determination of the relative quantities of the two substances depends on the fact that the optical rotatory power of borneol varies but little with the nature of the solvent, whilst in the case of isoborneol the variations are considerable.—H. J. E.

Inchi grass (Cymbopogon cæsius, Stapf); Essential oil from ——. K. L. Moudgill and K. R. K. Iyer. Perf. and Ess. Oil. Rec., 1922, **13**, 292—295.

The characters of the oil (yield 0·8%) were: Soluble in 87% alcohol; sp. gr. at 30°/4° C., 0·9187; $n_D^{30}=1{\cdot}484$; $[\alpha]_D^{30}=-38{\cdot}9°$; acid value, 1·7; saponif. value, 5·6; acetyl value, 120; percentage of aldehydes (Bennett's hydroxylamine method), 4·2. The oil is not identical with any of the known commercial oils from allied grasses, and may be used as a substitute for palmarosa oil, which it resembles in odour. It contains *l*-borneol, *l*-camphene, *l*-limonene, *l*-terpineol, and unidentified sesquiterpene constituents.—H. C. R.

Theobromine and caffeine. Schaap. *See* XIXA.

Modified Schiff's solution. Wertheim. *See* XXIII.

Hæmoglobin. Terrill. *See* XXIII.

Patents.

Allylarsenic acid; Manufacture of ——. F. Hoffmann-La Roche u. Co. A.-G. E.P. 167,157, 29.6.21. Conv., 26.7.20.

Allylarsenic acid, colourless needles or coarse prisms, m.p. 129°—130° C., is prepared by treating a tertiary alkali arsenite, in aqueous solution and in the presence of an excess of alkali, with allyl halides.—H. W.

Acetone; Method of manufacturing —— from acetic acid. Stockholms Superfosfat Fabriks Aktiebolag. E.P. 171,391, 9.11.21. Conv., 9.11.20.

A catalyst is employed with metallic aluminium as a carrier. It is prepared by slowly cooling molten aluminium, with vigorous stirring, to obtain it in a porous and granular form. This metal is then placed in a solution or suspension of the catalyst substance and the liquid evaporated off. The tube containing such a catalytic preparation can be uniformly heated without difficulty and the difference of temperature in the catalytic mass nearest to the walls of the tube and in the central parts is small even if a tube of considerable size is employed. Acetone is produced from acetic acid in good yield and of a very high degree of purity by passing acetic acid over the heated catalyst prepared as described.—J. R.

Remedy for malignant tumor [colloidal metallic selenides and tellurides]; Manufacture of a ——. L. Lilienfeld. E.P. 173,507, 22.12.21. Conv., 23.12.20.

Colloidal selenides or tellurides of such metals as gold, iridium, platinum, mercury, silver, copper, etc. are obtained by the action of hydrogen or alkali selenides and tellurides on dilute solutions of the respective metallic salts in the presence or absence of protective colloids, such as gelatin, casein, starch, dextrin, soaps, etc., or the water-soluble alkylpolysaccharides, such as methylcellulose or ethylstarch. If the latter substances are used the colloidal selenide or telluride may be separated by coagulating the alkylcellulose or alkylstarch by heating to 50°—80° C., and the coagulum can be filtered off, and thoroughly washed with hot water, and the product may, if desired, be dissolved in alcohol and precipitated with ether, before it is finally dried. If other protective colloids, or none at all, are used, coagulation by heat is not feasible and other purifying methods such as dialysis must be employed.—G. F. M.

Esters; Process of converting organic acids into ——. P. Haddan. From E. Zollinger-Jenny. E.P. 183,897, 4.4.21.

The conversion of organic acids, other than polyhydroxy-fatty acids, into esters is greatly simplified and accelerated by the use of zinc or tin or other metal of the periodic group including tin. The metal need not necessarily be in the finely-divided state; it may be introduced into the apparatus in the form of a regulus or be applied to the floor or wall or to a body inserted in the vessel. As soon as the temperature of reaction is reached and maintained, the conversion sets in and proceeds with considerable speed until the mixture is neutral. It is not essential to have an excess of the alcoholic component; the mixture may be in stoichiometrical proportions. Organic acids of the highest molecular weight, including resin acids, can be converted into esters in this way and the process can be applied not only to pure, free fatty acids but also to fatty acids mixed with fat or diluted with primary monohydric or other alcohols. An example is given of the esterification of a mixture of copra oil waste and copra fat acids with glycerin. [Reference is directed, in pursuance of Sect. 7, Sub-Sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 112,624; J., 1919, 427 A.]—H. W.

Esters; Process for the manufacture of ——. A. A. Backhaus, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,425,625, 15.8.22. Appl., 11.10.19.

The ester formed by heating a mixture of an alcohol and an organic acid in the presence of a catalyst is continuously removed by distillation; the major portion of the other vapours accompanying the ester is condensed and returned to the reaction vessel.—D. F. T.

Ichthyol oil, ichthyol preparations and the like; Manufacture of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 184,292, 21.5.21.

Ichthyol oil is obtained in better yield and containing a higher proportion of sulphidic sulphur than has hitherto been found possible by subjecting Seefeld or other sulphurised shales to high-speed mechanical disintegration in presence of water in a "colloid mill." The oil in the shale is thereby dispersed to form a permanent emulsion with the water, whilst the mineral matter separates out on standing. To obtain the oil from the emulsion, the latter is heated to 60°—70° C., if desired, with the addition of an electrolyte, *e.g.*, hydrochloric acid. The oil can be further purified by solution in an organic solvent. The purified oil contains about 20% of sulphidic sulphur, compared with about 8% in preparations hitherto obtained. The emulsions of oil and water obtained as above described can be themselves used to advantage for therapeutic purposes, either with or without the addition of protective colloids, as they are readily absorbed by the skin. Sulphonation of the ichthyol to obtain a water-soluble product and the concomitant partial decomposition which ensues are thereby obviated.
—G. F. M.

Acetic anhydride; Manufacture of ——. H. W. Matheson and G. E. Grattan, Assrs. to Shawinigan Laboratories, Ltd. U.S.P. 1,425,500, 8.8.22. Appl., 25.4.18.

Acetylene is passed through acetic acid (96—100%) heated to 60°—200° C. in the presence of a finely-divided salt of mercury.—J. R.

Chlorine products from unsaturated hydrocarbons; Process for producing ——. A. E. Maze. U.S.P. 1,425,669, 15.8.22. Appl., 16.8.20.

Acetylene is passed into an alkaline solution of an alkali metal which has been saturated with chlorine.
—D. F. T.

Borneols and camphene; Manufacture of ——. B. T. Brooks, Assr. to The Viscoloid Co. and The Fiberloid Corp. U.S.P. 1,426,036, 15.8.22. Appl., 6.4.20.

The mother liquor obtained after the separation of crystallisable bornyl chloride from the product of the action of dry hydrogen chloride on pinene, is treated with a fatty acid in presence of an alkali salt of a fatty acid, and a bornyl ester and camphene are thereby obtained.—G. F. M.

Methyl sulphites of secondary aromatic aliphatic amines and process of making same. M. Bockmühl and K. Windisch, Assrs. to Farbw. vorm. Meister, Lucius, und Brüning. U.S.P. 1,426,348, 22.8.22. Appl., 16.7.21.

Compounds of the general formula,

$$RR'N.CH_2.OSO_2M,$$

where R and R′ are an aromatic and an aliphatic radicle respectively, and M an alkali metal, or ammonium, are obtained by condensing secondary aromatic aliphatic amines of the type RR′NH with a formaldehyde-bisulphite compound.
—G. F. M.

Pharmaceutical product. H. Weyland, H. Hahl, and R. Berendes, Assrs. to Farbenfabr. vorm. F. Bayer und Co. U.S.P. 1,426,430, 22.8.20. Appl., 8.8.21.

The condensation product obtained from xylene, sulphur, and aluminium chloride is a valuable

remedy for scabies. It forms a dark yellow oil, b.p. 150°—230° C. at 3—5 mm. pressure.
—G. F. M.

Aldehydes; Apparatus for making —— and separating them from other products formed. A. A. Backhaus and F. B. Arentz, Assrs. to U.S. Industrial Alcohol Co. U.S.P. 1,426,449, 22.8.22. Appl., 24.6.18.

The apparatus consists of a combination of a catalyser chamber, a means for passing alcohol vapours through it to form an aldehyde and hydrogen, an alcohol condenser, and a means for separating the resulting aldehyde and hydrogen consisting of a scrubber, by means of which acetic acid is brought into contact with the vapours on the counter-current principle.—G. F. M.

Calcium chloride preparation; Process for preparing a non-hygroscopic, easily soluble ——. Calcion Ges. m.b.H. G.P. 354,247, 12.4.19.

The known process for the preparation of diglycollic acid by introducing lime into monochloroacetic acid is modified by evaporating to dryness the solution of calcium chloride and calcium diglycollate obtained. The product obtained is stable to changes of temperature, easily soluble, contains 30% $CaCl_2$, and is useful in therapeutics. A product developing strong alkalinity in the body is often required in this connexion. This can be obtained by replacing part of the lime with an alkali, such as sodium hydroxide. A mixture of calcium chloride, calcium diglycollate, and sodium diglycollate is thus obtained, and the last-named compound changes to sodium carbonate in the body and facilitates the absorption of the calcium chloride.—H. C. R.

Acridine derivatives; Preparation of ——. L. Casella und Co., G.m.b.H. G.P. 354,400, 21.12.17.

Aliphatic aldehydes are allowed to react, preferably in dilute mineral acid solution, with 3.6-diamino-10-alkylacridinium compounds or their substitution products. With formaldehyde at ordinary temperatures acridinium compounds yield products insoluble in water and useful for antiseptic purposes as dusting powders. If the reaction is carried out at 100° C. the resulting products are more soluble and may be used medicinally for certain skin diseases. With acetaldehyde in *N*/1 hydrochloric acid solution 3.6-diamino-10-methylacridinium chloride gives at ordinary temperatures a powdery dark reddish-brown condensation product that on drying assumes a green metallic lustre. It dissolves in hot water to an orange-red solution which dyes cotton mordanted with tannin in orange-yellow shades which are fast to soap, soda, and acids. If the condensation is effected at 100° C under a reflux condenser, a reddish-brown lustrous powder is obtained, which is readily soluble in water and dyes cotton mordanted with tannin various shades of red. Similar products may be obtained from other acridinium derivatives on condensation with formaldehyde or acetaldehyde; they all dye cotton in yellow to red shades.—A. R. P.

Trypsin-hydrochloric acid preparations; Process for making stable ——. A.-G. für Anilin-Fabr. G.P. 354,481, 19.2.18.

Preparations containing trypsin, such as *Pancreatinum activum* or *absolutum*, or their compounds with tannic acid, are mixed in the dry state with betaïne hydrochloride or betaïne hydrochloride and pepsin. The mixture retains the properties of trypsin even after long storage. It is useful in the treatment of diseases of the stomach and intestines.—H. C. R.

Tropinemonocarboxylic acids; Process for the preparation of ——. E. Merck, O. Wolfes, and H. Maeder. G.P. 354,696, 17.10.20.

A mixture of acetonedicarboxylic acid, methylamine, and succinic dialdehyde is reduced in a neutral or faintly acid or alkaline solution; for example, a mixture of calcium acetonedicarboxylate, methylamine, and succinic dialdehyde is acidified with acetic acid and reduced with 3% sodium amalgam with the addition of acetic acid from time to time to keep the mixture just acid. After acidification with sulphuric acid and removal of calcium sulphate, the solution is rendered alkaline with caustic potash and the tropine bases are extracted by shaking with ether. The alkaline solution is neutralised, concentrated, and stirred with methyl alcohol to precipitate salts which are filtered off. The methyl alcohol solution contains severally optically inactive isomeric tropinemonocarboxylic acids which can be separated only with great difficulty. From one of the isomers, which is identical with ecgonine, a methyl ester, m.p. 122°—126° C., may be obtained. When treated with benzoic anhydride in benzene solution, this yields a benzoyl derivative, which, after recrystallisation from light petroleum ether, melts at 79°—80° C. and is identical with optically inactive cocaine. The reduction process may be carried out in alcoholic or alkaline solution or with metallic sodium in ethereal solution but not with strongly acid reducing agents, such as tin and hydrochloric acid.
—A. R. P.

Esters of tropinonedicarboxylic acid; Preparation of ——. E. Merck, O. Wolfes, and H. Maeder. G.P. 354,950, 29.6.20.

Solutions of succinic dialdehyde in water, of esters of acetonedicarboxylic acid in alcohol, and of methylamine and caustic potash in water are carefully mixed together and the mixture is kept cooled for several hours, after which the product is neutralised with acid and the alcohol distilled off. The residue is treated with ammonia and shaken several times with chloroform. The chloroform solution is separated and the solvent distilled, whereby diethyl tropinonedicarboxylate remains behind as a viscous uncrystallisable oil, slightly soluble in water with a weak alkaline reaction and more readily soluble in alcohol, ether, chloroform, and ethyl acetate. It gives a reddish-violet colour with ferric chloride, instantaneously decolorises bromine water and permanganate solution, and unlike tropinonemonocarboxylic acid esters, forms no solid hydrate with water. Boiling with acids yields tropinone, while careful saponification gives the ethyl ester of the monocarboxylic acid.—A. R. P.

Basic aluminium salicylate; Method for the preparation of ——. Soc. Chim. Usines du Rhône. G.P. 354,698, 29.6.21.

Aluminium hydroxide and salicylic acid are mixed in molecular quantities, in presence of water; warming facilitates the reaction. The product is a colourless, occasionally reddish, powder, containing 25·75% Al_2O_3 and having the formula, $C_6H_4(OH)CO_2.Al(OH)_2$. It is distinguished from the normal salicylate by its stability when heated with water and dilute acid. It passes undecomposed through the stomach and is a remedy for intestinal catarrh and diarrhœa.—J. B. F.

Colloidal suspensions; Process of producing stable —— in organic media immiscible with water. H. Karplus. G.P. 355,109, 31.5.18. Addn. to 293,848.

Two colloidal suspensions prepared in accordance with G.P. 293,848 and 296,637 (*cf.* E.P. 8640–1 of

1915; J., 1916, 601, 823) are simultaneously or successively dispersed in the same organic medium. One of the colloidal substances is a compound of the magnesium or aluminium group prepared in accordance with the previous patents.—J. S. G. T.

Acoine; Process for making clear solutions of —— in oils. G. Hirsch. G.P. 355,121, 13.3.18.

Acoine (di-*p*-anisylmonophenetylguanidine hydrochloride) is gradually added to the oil heated to its boiling point in such a way that the acoine does not come in contact with the walls of the containing vessel. The oily solution is used as a dispersing medium for insoluble mercury salts to allow of the painless incorporation of the latter in the human body.—H. C. R.

Serum and lymph preparations; Process for making stable ——. L. Cassella und Co., G.m.b.H. G.P. 355,415, 21.11.19.

The raw material is treated with acridine dyestuffs. For example, in the preparation of small-pox vaccine, the raw lymph is mixed with 3—5 times the quantity of a sterilised 1% solution of 3.6-diamino-10-methylacridinium chloride (Neutra-trypaflavine), and is then worked up in the usual manner. The trypaflavine lymph is distinguished from glycerol lymph by its green colour and its fluidity. The preservative power of the acridine dyestuffs is greater than that of glycerol or of the phenols usually employed. The action of sera and lymphs is not in any way affected by acridine dyestuffs, which, not being poisonous, are incapable of producing any harmful effects.—H. C. R.

Ethyl alcohol; Production of —— from acetylene or ethylene. W. Karo. G.P. 356,175–6, 16.3.19, and 19.9.20.

Ethylene or acetylene, mixed with hydrogen and oxygen and sufficient inert gas to render the mixture non-explosive, is passed over a catalyst consisting of a mixture of two or more finely divided metals on a suitable carrier, one metal at least being of the platinum group and one a less noble metal, such as copper, nickel, or iron. If the hydrocarbon is purified by passing it through solutions of copper sulphate in sulphuric acid and of bichromate in sulphuric acid no dilution with inert gas is necessary. By passing a mixture of 2 vols. of ethylene, 2 vols. of hydrogen, 1 vol. of oxygen, and 1 vol. of nitrogen or of 2 vols. of acetylene, 4 vols. of hydrogen, 1 vol. of oxygen, and 1 vol. of nitrogen over a nickel-palladium catalyst at 100° C., a yield of 12% of alcohol in the former and 8—10% in the latter case is obtained.—A. R. P.

Acetaldehyde; Process of manufacturing ——. H. W. Matheson. Reissue No. 15,434, 22.8.22, of U.S.P. 1,384,842, 19.7.21. Appl., 5.5.22.

See E.P. 132,557 of 1918; J., 1919, 845 A.

Dinitroglycol and its homologues; Process for the preparation of ——. H. Oehme, Assr. to The Chemical Foundation, Inc. U.S.P. 1,426,313, 15.8.22. Appl., 27.6.19.

See G.P. 338,056 of 1918; J., 1921, 640 A.

Amines. E.P. 184,234. *See* III.

Mercury. G.P. 356,507. *See* VII.

Acids from distillery waste. U.S.P. 1,426,457. *See* XVIII.

XXI. — PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsion; Theory of the characteristic curve of a ——. F. C. Toy. Phil. Mag., 1922, 44, 352—371.

The relation between the number of silver halide grains made developable and the light intensity has been studied for a number of grain sizes. The curves obtained by plotting the percentage of grains made developable against the log. of the intensity of light possess the characteristic S shape only for the grain size of $0{\cdot}98\mu^2$. Larger grains give curves in which the first point of inflexion is absent. A theory of the photographic plate is based on these results. The halide grains are assumed to contain sensitive nuclei, which are capable of change under the action of light in such a way as to become developable. These nuclei are produced during the precipitation and ripening of the emulsion and are not composed of silver halide. They are distributed throughout the grains according to the laws of chance, some particles possessing several nuclei. Those in the larger grains appear to be the more sensitive. Svedberg's assumption regarding the similarity of the light-sensitive material in large and small grains is not in agreement with the experimental facts in the case of a fast emulsion.
—W. E. G.

Photographic emulsions; Mutual infection of contiguous silver halide grains in ——. A. P. H. Trivelli, F. L. Righter, and S. E. Sheppard. Phot. J., 1922, 46, 407—410.

The authors claim to show that in the case of an emulsion containing flat, polyhedral grains, the individual grain is not the photographic unit, but that the grains are capable of mutually infecting each other. In the case of a clump of two or more grains, if one grain is reducible, the whole clump develops completely as a unit. This is in direct conflict with the results obtained by Svedberg (J., 1922, 348 A) with spherical grains, and it is suggested that the spherical grains and the flat, polyhedral grains represent two extreme cases.
—W. C.

Photochlorides and colloidal silver; Colour of ——. K. Schaum and T. Marx. Kolloid-Zeits., 1922, 31, 64—70. (*Cf.* J., 1921, 561 A.)

A method of determining the real colour of colloidal particles is described, and using this method it is shown that the faintly reflecting red particles of colloidal silver are in reality yellow, the red colour being due to a colour contrast with the many green particles also present. The colour range obtained in photographic intensification may be completely reversed in photographic reduction as follows: a blue silver sol is mixed with an equal volume of a 10% gelatin solution and allowed to set, then a concentrated solution of ammonia, potassium cyanide or sodium thiosulphate is poured on it and allowed to diffuse. After several days the following range of colours is observed commencing at the top of the tube: colourless, yellow, orange, red, reddish-violet, bluish-violet, and blue. Silver sols of various colours may be produced by the addition of definite amounts of magnesium sulphate, ammonium chloride, sodium chloride, or potassium sulphate. Thus with a yellow silver sol, 0·10 c.c. of $N/2$ magnesium sulphate gives an orange sol, 0·20 c.c. red; 0·25 c.c. purple; 0·30 c.c. reddish-violet; 0·50 c.c. bluish-violet, and 1·50 c.c. blue.—J. F. S.

Patents.

Photography; Process of producing multicoloured screens for ——. I. Kitsee. U.S.P. 1,426,995, 22.8.22. Appl., 17.1.19.

Figurations are produced on the gelatinous sub-

stratum of a moving picture film by means of a coloured alcoholic solution containing a dissolved resin, and the interspaces between these figurations are coloured with the aid of a dye insoluble in alcohol. By this means a multicoloured screen integral with the moving picture film is obtained.
—W. C.

Ferroprussiate paper; Manufacture of ——. E. Bertsch. G.P. 354,388, 16.10.20. Addn. to 320,981 (J., 1920, 676 A).

A simple acid salt is added to the emulsion in addition to excess of normal alkali oxalate. The advantages claimed are quicker printing and that the paper remains yellow for a longer time.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Some changes undergone by ——. A. Angeli. Z. ges. Schiess- u. Sprengstoffw., 1922, 17, 113—115.

The action of pyridine on collodion-cotton (12% N) was studied with the object of elucidating the changes undergone by the basic organic stabilisers usually added to nitrocellulose and nitroglycerin powders. The nitrocotton was extraordinarily easily gelatinised by the pyridine, forming a very viscous liquid which, however, rapidly lost its viscosity and in a few days had the appearance of ordinary pyridine. On adding water to the solution a white resinous mass was precipitated which tenaciously retained the smell of pyridine even after solution in sulphuric acid. The white powder obtained represented 80% of the weight of collodion-cotton used, was easily soluble in acetic acid, soluble in alcohol, but almost insoluble in ether and benzene. It burnt much more slowly than the original nitrocotton. Its nitrogen content varied between 9% and 10%. The substance was similar to that obtained by Berl and Fodor (J., 1910, 978, 1083) by the action of alkali hydroxides or carbonates on very dilute solutions of nitrocellulose in alcohol and ether. Heated in a glass tube the substance began to turn brown at 165° C. and became almost black at 250° C. An alcoholic solution of the substance when poured into water gave a very stable opalescent colloidal solution, which was coagulated by sodium chloride, ammonium sulphate, or gelatin, but gave no precipitate with aqueous tannin. The substance reacts readily with phenylhydrazine. Paper saturated in dimethylaminoazobenzene after a short time becomes intensely red in colour when subjected to the action of the wet compound, showing the development of an acid reaction. This is attributed to the volatilisation of the pyridine or the hydrolysis of the pyridine salt by water. The use of weak organic bases as stabilisers for nitrocottons is considered objectionable on account of the possibility of the production of acidic products through hydrolysis. Diphenylamine remains present as such in nitrocottons much longer than other organic bases. This may be due to it being such a weak base that it is only capable of reacting with nitrous acid to form the nitrosamine.—H. C. R.

Smokeless powders; Testing —— *for acidity.* A. Angeli. Z. ges. Schiess- u. Sprengstoffw., 1922, 17, 115—116.

The propellant is finely divided, suspended in water, and treated with a few drops of a 0·2% solution of dimethylaminoazobenzene. If no acids are present the particles of propellant remain of a lemon-yellow colour. In cases where acidity has developed they are coloured a more or less intense red. The liquid in which the propellant is suspended remains in either case entirely colourless.
—H. C. R.

Mercury oxycyanide; Explosibility of ——. H. Kast and A. Haid. Z. ges. Schiess- u. Sprengstoffw., 1922, 17, 117.

Mercury oxycyanide blackens and gives off smoke without flame on being strongly triturated in a porcelain mortar. It decomposes when struck by a 2 kg. weight falling 40 cm., and explodes with a similar weight falling 60 cm. With a 10 kg. weight the heights are 10 cm. and 16 cm. respectively. It is therefore more sensitive than gunpowder and picric acid and less so than tetryl. Ignited by a flame or red hot substance it burns with a pale red flame, but cannot be ignited by the sparks from pyrophoric cerium alloys. Its rate of burning in the open is greater than that of tubular smokeless powder but much less than that of gunpowder. It ignites at 170° C. in a bath of Wood's metal. Tested in the Trauzl block it gave an increase of volume of 10 c.c. without correcting for the detonator used. Assuming decomposition according to the formula $Hg(CN)_2,HgO=2Hg+C+CO+N_2+64{\cdot}5$ cals., the gas evolved per kg. is 190 l., heat per kg. 138 cals., temperature of explosion 2620° C., and specific energy 2090 kg.-litres, these figures being considerably less than those accepted for gunpowder.—H. C. R.

Patents.

Ammonium perchlorate explosives; Process for making easily cast ——. Chem. Fabr. von Heyden A.-G. G.P. 306,370, 2.9.17.

Ammonium perchlorate is mixed with nitrates of nitrogenous bases, especially ammonium nitrate, and salts of fatty acids or hydroxy-fatty acids, free hydroxy-fatty acids, amides of aliphatic carboxylic acids, sulphuric esters, and where necessary dihydroxybenzenes, aromatic hydroxy-acids and sulphonic acids or their salts. In addition to being easily cast these explosives are characterised by giving little noxious vapour on explosion when the compounds mixed with the perchlorate are in the form of alkali salts.—H. C. R.

Shells; Process for filling projectiles such as —— *with an explosive mixture consisting mainly of ammonium nitrate and charcoal.* Verein Chem. Fabr. in Mannheim. G.P. 310,130, 9.9.17.

The oxidising agent is melted alone and the charcoal is stirred into the melt, preferably in a vessel other than that used for melting the first constituent, *e.g.*, in a measuring vessel containing exactly the charge for one shell, and provided with heating and stirring arrangements. The charcoal mixes better if it is previously briquetted, the binding material used being ammonium nitrate. In this way shells may be rapidly and safely filled with a very effective explosive.—H. C. R.

Explosive and propellant; Process for preparing an —— *from ammonium nitrate and nitrates, oxalates, and similar salts of ammonium and amines.* Verein Chem. Fabr. in Mannheim. G.P. 334,547, 8.12.16.

The mixture is liquefied and re-solidified in a homogeneous or nearly homogeneous condition. For example the solvent is rapidly evaporated from a solution of the components by allowing the concentrated solution to flow over steam-heated rolls, from which the solidified mass may be removed by scrapers. Alternatively the constituents may be melted together at as low a temperature as possible and the melt rapidly cooled.—H. C. R.

Match composition. M. Pohl. G.P. 347,120, 30.5.20.

The addition of lignite to a mixture of potassium chlorate, sulphur, clay, binding materials, and filling materials, is proposed.—H. C. R.

XXIII.—ANALYSIS.

Stalagmometer and stagonometer; A new ——. I. Traube. Biochem. Zeits., 1922, **130**, 476.

The stalagmometer described previously (J., 1922, 121 A) is not suitable for measurements of viscosities.—H. K.

Analysis; Refractometric and interferometric quantitative ——. I. Becka. Z. physiol. Chem., 1922, **121**, 288—299.

The author has extended the observations of de Crinis on the use of the refractometer for the analysis of solutions so as to make it more generally applicable. He also describes the use of the interferometer for more dilute solutions. The experiments have special reference to urine analysis. —H. K.

Ion concentration measurements; Application of —— to the control of industrial processes. E. A. Keeler. J. Ind. Eng. Chem., 1922, **14**, 395—398.

Several forms of electrodes are described which are suitable for industrial work and examples are given of the application of the hydrogen-ion method to the control of neutralisation processes in the case of such materials as pineapple juice, tooth pastes, beet sugar juice (carbonatation process), wool scouring liquor, tanning liquors, boiler feed water, etc. —W. P. S.

Heat of combustion of benzoic acid, sucrose, and naphthalene. W. Swietoslawski and H. Starczewska. Bull. Soc. Chim., 1922, **33**, 654—667.

Further experiments have been made in order to obtain standard values; the results are in accord with those of Dickinson (J., 1915, 411). The most probable value for the heat of combustion of benzoic acid, which is recommended as standard, is 6323 cals. per g. in air, at 15° C., or 6318 cals. per g. *in vacuo*. (*Cf.* J., 1922, 328 R.)—H. J. E.

Osmium; Recovery of —— from microscopical preparations. O. Bosse and H. von Wartenberg. Z. wiss. Mikros., 1922, **38**, 346—349. Chem. Zentr., 1922, **93**, III., 119.

The material is saponified with caustic potash, evaporated, and the soap fused with potassium nitrate in a nickel crucible. The melt is treated with water, and nickel sulphate solution added. On standing nickel hydroxide, part of which becomes oxidised to the hydrated peroxide, settles out carrying with it the osmium. The precipitate is filtered off, and the precipitate and filter transferred to a 250 c.c. flask fitted with a ground-in dropping funnel and provided with a drain tube. The precipitate is treated with a mixture of chromic and sulphuric acids and kept warm. The contents of the flask are then steam distilled, and a solution of pure osmium tetroxide is obtained. An iron crucible cannot be used because too much iron passes into solution during fusion producing an inconvenient amount of hydroxide. In the authors' experiments 70% of the osmium was recovered.—J. B. F.

Micro-analysis of mixtures with special reference to organic ultimate analysis. A. Benedetti-Pichler. Z. anal. Chem., 1922, **61**, 305—331.

The application and advantages of microchemical methods of analysis are described; the importance of obtaining a representative sample for analysis is emphasised and limits of error are discussed. —W. P. S.

Isotopes of lead; Chemical method of separating ——. T. Dillon, R. Clarke, and V. M. Hinchy. Sci. Proc. Royal Dublin Soc., 1922, **17**, 53—57.

Lead chloride recovered from residues from the manufacture of mesothorium has been made to react with magnesium ethiodide according to the equation:

$$2PbCl_2+4MgC_2H_5I=Pb(C_2H_5)_4+2MgCl_2+2MgI_2+Pb,$$

and the atomic weight of the lead in the tetraethyl compound and the metal lead determined. The values 207·1 and 207·4 were obtained, indicating that the isotopes of lead react differently with magnesium ethyl iodide and showing the possibility of separating the isotopes by this reaction.—J. F. S.

Oxygen in organic compounds; Determination of ——. H. ter Meulen. Rec. Trav. Chim., 1922, **41**, 509—514.

The substance to be analysed is heated in a current of pure dry hydrogen and the resulting gas passed over reduced nickel, the water produced being collected and weighed. The results appear to be accurate when proper precautions are taken. The hydrogen is washed in permanganate solution, dried in sulphuric acid, freed from traces of oxygen by passing over heated platinised asbestos and then over calcium chloride. It is then brought into contact with the material to be analysed (0·1—0·2 g. heated in a platinum boat contained in a quartz tube) and passed over finely divided nickel which is maintained at a bright red heat, afterwards being brought into contact with nickelised asbestos heated to 350°—400° C. in a spiral hard glass tube. It is in the spiral tube that the transformation into water occurs and the product is then passed through calcium chloride tubes, and finally through a soda-lime tube to collect any carbon dioxide that has escaped reduction. The method is not applicable to substances which contain halogens or sulphur, which act as catalyst poisons, nor is it available in the case of nitrogenous substances, as the ammonia formed on hydrogenation is retained by the calcium chloride.—H. J. E.

Schiff's solution; A modified —— [for detection of aldehydes]. E. Wertheim. J. Amer. Chem. Soc., 1922, **44**, 1834—1835.

A solution of rosaniline hydrochloride (0·005 g.) in hot water (50—100 c.c.) is filtered, if necessary, diluted to 300 c.c., and cooled with running water. Sodium hydrosulphite (6 g.) is added to the cooled solution. The salt dissolves completely in a few minutes, after which the solution is ready for use. If it is boiled for 1 min. (not longer) it first becomes red and subsequently almost colourless. It may then be heated in testing for aldehydes in order to hasten the test. Used in this manner the solution gives the aldehyde test in about half the time required for the ordinary Schiff's test, although without heating it usually requires a little longer time than the customary Schiff's solution. Special precautions in preserving it are unnecessary.—H. W.

Hæmoglobin; Colorimetric determination of —— with especial reference to the production of stable standards. E. H. Terrill. J. Biol. Chem., 1922, **53**, 179—191.

Two modified methods for the preparation of acid hæmatin standards are described. A concentrated stock solution is prepared by removing the serum from defibrinated or oxalated blood, adding water, acidifying, filtering, and concentrating by means of an electric fan. The second method yields an acid hæmatin protein powder which is quite stable in the dry state and forms clear solutions in water and in $N/10$ HCl. In estimating hæmoglobin, the laking of the blood with water prior to acidification is recommended. Direct acidification produces a turbidity which leads to high results when a clear standard is used.* Heat should not be employed o develop maximum colour as this again produces a turbidity.—E. S.

Suspended matter in gases; Determination of —— by collection on filter paper. S. H. Katz and G. W. Smith. Gas World, 1922, 77, 160—161.

DETERMINATIONS were made of the efficiency of filter paper for the removal of tar (tobacco smoke) from air, the tests being carried out in a " tar camera " (J., 1918, 475 B), and the determination of tar present before and after filtering made by means of the Tyndall effect. The filtering efficiencies of single sheets of filter paper supplied with the apparatus ranged from 63 to 90%. The efficiencies of higher grade filter papers were greater than 90%. Four layers of filter paper retained all tar. For quantitative determinations the paper should be dried and weighed between clipped watch glasses. A period of two hours drying *in vacuo* should be allowed before weighing, followed by a further drying for one hour and check weighing. Quantitative results only can be obtained by comparison of the tar filter with a colour chart, the average error, in the present experiments, ranging from 38 to 57%.—J. S. G. T.

Patents.

Calorific value of gas; Method of and apparatus for measuring the ——. J. S. Withers. From E. R. Lanphier. E.P. 184,025, 6.7.21.

GAS is burned in a Bunsen burner, previously adjusted to burn completely a gas of known calorific value. A sleeve threaded on the burner tube and controlling the admission of primary air to the burner is adjusted until the luminous tip of the flame just disappears. The calorific value is then read by means of a micrometer head, provided on the upper end of the sleeve and moving over a scale of calorific values engraved on the burner tube.
—J. S. G. T.

Analysis and recording [of the volumetric composition] of gases; Apparatus for the ——. A. G. Dale. E.P. 184,279, 12.5.21.

GAS is continuously drawn through a gas analysis apparatus by means of a water ejector, and an oscillating element moving in a cylinder traps a definite volume of gas from the stream and forces it through an absorbing liquid to the recording vessel, such as a float chamber in which hangs an oil-sealed metal float which rises to a height proportional to the volume of gas passing into the float. The rise or fall of the float operates a pen mechanism. A U-tube water gauge connected with the main gas pipe serves to indicate the cleanliness of the pipe line and soot filter employed.
—J. S. G. T.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

Renton. Filter presses. 25,577. Sep. 21.

Soward. Furnaces. 24,907. Sep. 14.

Complete Specifications Accepted.

10,704 (1921). Reid. Furnaces. (185,784.) Sep. 27.

12,220 (1921). Jewell. Stills. (185,451.) Sep. 20.

12,659 (1921). Greenwood, and Carr and Co. Apparatus for baking and drying substances at high temperatures. (185,460.) Sep. 20.

13,411 (1921). Pennell. Filtration of turbid water or liquid. (185,796.) Sep. 27.

15,884 (1921). Buxton and Buxton. Rotary multiple drying cylinder. (185,823.) Sep. 27.

16,394 (1921). Aktiebol. Cellulosa. *See* V.

17,203 (1921). Blair, Campbell, and McLean, and Ferguson. Evaporators and distilling apparatus. (185,873.) Sep. 27.

17,395 (1921). Plauson's (Parent Co.), Ltd. (Plauson). High speed disintegrators. (185,878.) Sep. 27.

22,242 (1921). Hutchins. Making emulsions. (185,618.) Sep. 20.

28,602 (1921). Monkbridge Iron and Steel Co., Kitson, and Brown. Furnaces. (185,668.) Sep. 20.

31,905 (1921). Prym. Filling bodies for absorption and reaction towers. (185,681.) Sep. 20.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Aguillon. Recovering benzol contained in gas. 25,377. Sep. 19.

Breisig. Gasifying bituminous fuel. 25,378. Sep. 19.

Broadhead, and Dempster and Sons. Manufacture of gas. 24,961. Sep. 15.

Day. Extracting hydrocarbon oil material from oil-bearing earthy material. 25,211. Sep. 18.

Evans, and South Metropolitan Gas Co. Manufacture of smokeless fuel. 25,231. Sep. 18.

Johnstone. Purification of lubricating etc. oil. 24,981. Sep. 15.

Neath. Manufacture of gas from coal and oil. 25,790. Sep. 23.

Quick. 25,429. *See* XII.

Roots. Gas-generator. 25,140. Sep. 16.

Sutcliffe. Apparatus for distilling carbonaceous substances. 24,624. Sep. 11.

Sutcliffe. Briquetting fuel etc. 25,731. Sep. 22.

Wilson. Synthetic coal. 25,649. Sep. 22.

Complete Specifications Accepted.

7747 (1921). Goold (Universal Oil Products Co.). Production of cracked petroleum oils. (185,439.) Sep. 20.

8723 (1921). Low Temperature Carbonisation, and Davidson. Retorts for distilling coal and other carbonaceous substances. (185,778.) Sep. 27.

10,084 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of oily pastes or emulsions from mineral and other oils. (185,779.) Sep. 27.

10,230 (1921). Cox, Kerr, and Baty. Gas purification. (185,780.) Sep. 27.

10,692 (1921). Meyer zu Eissen and Kiederich. Increasing the consistency of hydrocarbon oils and other oils and fats. (185,782.) Sep. 27.

12,675 (1921). Woodall, Duckham, and Jones, and Duckham. Carbonising fuel in vertical retorts. (185,461.) Sep. 20.

15,363 (1921). Piron. Recuperative coke-ovens. (185,811.) Sep. 27.

15,458 (1921). Klee. Apparatus for determining the flash point of oils etc. (185,814.) Sep. 27.

17,230 (1921). Deutsche Petroleum A.-G., Kaeser, and Bauer. Retorts for distillation. (165,724.) Sep. 27.

17,879 (1921). Murray. Manufacture of carburetted water gas, blue water gas, methane-hydrogen, and producer gas. (185,887.) Sep. 27.

22,803 (1921). Jensen (Stone). Oil-cracking process and apparatus. (185,624.) Sep. 20.

23,856 (1921). Niece. Cracking hydrocarbons. (185,632.) Sep. 20.

27,626 (1921). Climie. Gas-producers. (185,980.) Sep. 27.

32,546 (1921). Yeadon. System of low-temperature carbonisation. (185,684.) Sep. 20.

32,915 (1921). Healy. Gas-producers. (185,685.) Sep. 20.

III.—TAR AND TAR PRODUCTS.

Applications.

Aguillon. 25,377. *See* II.

Barrett Co. Manufacture of aromatic hydrocarbons. 24,727. Sep. 12. (U.S., 14,11.21.)

Pellegrini and Poma. Manufacture of acid H (aminonaphtholdisulphonic 1.3.6.8). 25,351. Sep. 19. (Ital., 12.12.21.)

Thompson (Atack). Manufacture of anthraquinone and derivatives thereof. 24,753. Sep. 13.

IV.—COLOURING MATTERS AND DYES.

Applications.

Carpmael (Bayer u Co.). Manufacture of intermediate products and their application for dyeing. 25,120. Sep. 16.

Durand et Huguenin Soc. Anon. Manufacture of products for dyeing etc. textile fabrics. 24,602. Sep. 11. (Fr., 16.9.21.)

Imray (Chem. Fabr. Griesheim-Elektron). Manufacture of monoazo dyestuffs. 25,232. Sep. 18.

Johnson (Badische Anilin u. Soda Fabrik). Manufacture of vat colouring matters. 25,121, 25,209, and 25,362. Sep. 16, 18, and 19.

Complete Specifications Accepted.

17,630 (1921). British Dyestuffs Corp., Baddiley, Payman, and Bainbridge. Manufacture of direct dyeing cotton colours. (185,880.) Sep. 27.

21,852 (1921). British Dyestuffs Corp., Green, Saunders, and Bate. Manufacture of triarylmethane colouring matters. (185,612.) Sep. 20.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bernini. Testing woollen and silk materials. 24,870. Sep. 14. (Ital., 27.5.22.)

British Cellulose and Chem. Manuf. Co., and Dreyfus. Manufacture of artificial filaments, threads, etc. 25,694. Sep. 22.

Hunt, and Hunt, and Moscrop. Boiling kiers for textile fabrics. 25,763. Sep. 23.

Complete Specifications Accepted.
